- If $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R/\mathfrak{a}$ is prime then regard any $a, b \in R$. Then $(a + \mathfrak{a})(b + \mathfrak{a}) = ab + \mathfrak{a} \in \mathfrak{p}/\mathfrak{a}$ is equivalent, to $ab \in \mathfrak{p}$ which again is equivalent, to $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$ (as $\mathfrak{p}$ is prime). And again this is equivalent, to $a + \mathfrak{a} \in \mathfrak{p}/\mathfrak{a}$ or $b + \mathfrak{a} \in \mathfrak{p}/\mathfrak{a}$. Hence $\mathfrak{p}/\mathfrak{a}$ is prime, too. For the converse implication just pursue the same arguments in inverse order.

- As the correspondence $\mathfrak{b} \longleftrightarrow \mathfrak{b}/\mathfrak{a}$ maintains the inclusion $\subseteq$ of subsets, it is clear that maximal elements mutually correspond to each other. That is $\mathfrak{m}/\mathfrak{a}$ is maximal, if and only if $\mathfrak{m}/\mathfrak{a}$ is maximal.

□

Proof of (1.76):

(i) Clearly $\varphi(0_R) = \varphi(0_R + 0_R) = \varphi(0_R) + \varphi(0_R)$ and subtracting $\varphi(0_R)$ from this equation (i.e. adding $-\varphi(0_R)$ to both sides of the equation) we find $0_S = \varphi(0_R)$. Hence $\varphi(a) + \varphi(-a) = \varphi(a - a) = \varphi(0_R) = 0_S$ which proves that $\varphi(-a)$ is the negative $-\varphi(a)$.

(ii) Analogous to the above we find $1_S = \varphi(1_R) = \varphi(uu^{-1}) = \varphi(u)\varphi(u^{-1})$ and $1_S = \varphi(1_R) = \varphi(u^{-1}u) = \varphi(u^{-1})\varphi(u)$ which proves that $\varphi(u^{-1})$ is the inverse $\varphi(u)^{-1}$.

(iii) If $a, b \in R$ then $\psi\varphi(a+b) = \psi(\varphi(a) + \psi(b)) = \psi\varphi(a) + \psi\varphi(b)$ and likewise for the multiplication. Hence $\psi\varphi$ is a homomorphism of semi-rings again. And in the case of rings and homomorphisms of rings we also get $\psi\varphi(1_R) = \psi(1_S) = 1_T$.

(iv) Consider any $x, y \in S$, as Φ is surjective there are $a, b \in R$ such that $x = \Phi(a)$ and $y = \Phi(b)$. Now $\Phi^{-1}(x+y) = \Phi^{-1}(\Phi(a) + \Phi(b)) = \Phi^{-1}\Phi(a+b) = a + b = \Phi^{-1}(x) + \Phi^{-1}(y)$. Likewise we find $\Phi^{-1}(xy) = \Phi^{-1}(x)\Phi^{-1}(y)$. And if Φ is a homomorphism of rings, then $\Phi^{-1}(1_S) = 1_R$ is clear from $\Phi(1_R) = 1_S$.

(v) Since $\mathrm{im}(\varphi) = \varphi(R)$ the first statement is clear from (vi) by taking $P = R$. So we only have to prove, that $\mathrm{kn}(\varphi)$ is an ideal of R. First of all we have $0_R \in \mathrm{kn}(\varphi)$ since $\varphi(0_R) = 0_S$ by (i). And if $a, b \in \mathrm{kn}(\varphi)$ then $\varphi(a+b) = \varphi(a) + \varphi(b) = 0_S + 0_S = 0_S$ and hence $a + b \in \mathrm{kn}(\varphi)$. Analogously $\varphi(-a) = -\varphi(a) = -0_S = 0_S$ yields $-a \in \mathrm{kn}(\varphi)$. Now let $a \in \mathrm{kn}(\varphi)$ again and let $b \in R$ be arbitrary. Then $\varphi(ab) = \varphi(a)\varphi(b) = 0_S\varphi(b) = 0_S$ and hence $ab \in \mathrm{kn}(\varphi)$ again. Likewise $\varphi(ba) = \varphi(b)\varphi(a) = \varphi(b)0_S = 0_S$ which yields $ba \in \mathrm{kn}(\varphi)$.

(vi) As P is a sub-semi-ring of R we have $0_R \in P$ and therefore $0_S = \varphi(0_R) \in \varphi(P)$. Now assume that $x = \varphi(a)$ and $y = \varphi(b) \in \varphi(P)$ for some $a, b \in P$. As P is a sub-semi-ring of R we have $a + b$, $-a$ and $ab \in P$ again. And hence $x + y = \varphi(a) + \varphi(b) = \varphi(a+b) \in \varphi(P)$, $-x = -\varphi(a) = \varphi(-a) \in \varphi(P)$ and $xy = \varphi(a)\varphi(b) = \varphi(ab) \in \varphi(P)$. Thus we have proved that $\varphi(P) \leq_{\mathrm{s}} R$ is a sub-semi-ring again. And if R and S even are rings, P is a sub-ring of R and φ is a homomorphism of rings, then also $1_S = \varphi(1_R) \in \varphi(P)$ as $1_R \in P$.

(vi) And as Q is a sub-semi-ring of S we have $0_S \in Q$ and therefore $0_S = \varphi(0_R)$ implies $0_R \in \varphi^{-1}(Q)$. Now suppose $a, b \in \varphi^{-1}(Q)$, that is $\varphi(a), \varphi(b) \in Q$. Then $\varphi(a+b) = \varphi(a) + \varphi(b)$, $\varphi(-a) = -\varphi(a)$ and $\varphi(ab) = \varphi(a)\varphi(b) \in Q$, as $Q \leq_{\mathrm{s}} S$. This means that $a + b$, $-a$ and $ab \in \varphi^{-1}(Q)$ and hence $\varphi^{-1}(Q) \leq_{\mathrm{s}} S$ is a sub-semi-ring of S. And in the case of rings we also find $1_R \in \varphi^{-1}(Q)$ as in (vi) above.

(vii) First assume that $\mathfrak{b} \leq_{\mathrm{m}} S$ is a left-ideal of S. We have already proved in (vi) that $\varphi^{-1}(\mathfrak{b}) \leq_{\mathrm{s}} S$ is a sub-semi-ring of S (since $Q := \mathfrak{b} \leq_{\mathrm{s}} R$). Thus it only remains to verify the following: consider any $a \in R$ and $b \in \varphi^{-1}(\mathfrak{b})$. Then $\varphi(b) \in \mathfrak{b}$ and as $\mathfrak{b} \leq_{\mathrm{m}} S$ we hence get $\varphi(ab) = \varphi(a)\varphi(b) \in \mathfrak{b}$. Thus $ab \in \varphi^{-1}(\mathfrak{b})$ which means that $\varphi^{-1}(\mathfrak{b})$ is a left-ideal of R again. And in the case that $\mathfrak{b} \trianglelefteq_{\mathrm{i}} S$ even is an ideal, then by the same reasoning $\varphi(ba) = \varphi(b)\varphi(a) \in \mathfrak{b}$ and hence $ba \in \varphi^{-1}(\mathfrak{b})$.

(vii) Next assume that $\mathfrak{a} \leq_{\mathrm{m}} R$ is a left-ideal of R and that φ is surjective. Then $\varphi(\mathfrak{a}) \leq_{\mathrm{s}} S$ is a sub-semi-ring of S by (vi) for $P := \mathfrak{a} \leq_{\mathrm{s}} R$. Thus it again remains to prove the following property: Consider any $y \in S$ and $x = \varphi(a) \in \varphi(\mathfrak{a})$ (where $a \in \mathfrak{a}$). As φ is surjective there is some $b \in R$ with $y = \varphi(b)$. And as $ba \in \mathfrak{a}$ we hence find $yx = \varphi(b)\varphi(a) = \varphi(ba) \in \varphi(\mathfrak{a})$. Thus $\varphi(\mathfrak{a}) \leq_{\mathrm{m}} S$

is a left ideal of S. And in the case that $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ even is an ideal, then by the same reasoning $xy = \varphi(a)\varphi(b) = \varphi(ab) \in \varphi(\mathfrak{a})$.

(viii) Let $\varphi : R \to S$ be a homomorphism of semi-rings. If $\varphi(1_R) = 0_S$ then for any $a \in R$ we get $\varphi(a) = \varphi(1_R a) = 0_S \varphi(a) = 0_S$ and hence $\varphi = 0$. Else we have $\varphi(1_R) = \varphi(1_R 1_R) = \varphi(1_R)\varphi(1_R)$ and dividing by $0 \neq \varphi(1_R)$ (i.e. multiplying by $\varphi(1_R)^{-1}$) we hence find $1_S = \varphi(1_R)$.

(ix) As we have seen in (v) $\mathrm{kn}(\varphi) \trianglelefteq_{\mathrm{i}} R$ is an ideal of R. And as R is a skew-field, it has precisely two ideals: $\{0\}$ and R. In the first case $\mathrm{kn}(\varphi) = R$ we trivially have $\varphi = 0$. And in the second case $\mathrm{kn}(\varphi) = \{0\}$ we will soon see, that φ is injective.

□

Proof of (1.77):
If $b \in \mathfrak{b} \subseteq \mathfrak{a} + \mathfrak{b}$ then $\varrho(b) = b + \mathfrak{a} \in (\mathfrak{a} + \mathfrak{b})/\mathfrak{a}$ is clear and hence $\varrho(\mathfrak{b}) \subseteq (\mathfrak{a} + \mathfrak{b})/\mathfrak{a}$. Conversely for any $a \in \mathfrak{a}$ and $b \in \mathfrak{b}$ we get $(a + b) + \mathfrak{a} = b + \mathfrak{a} = \varrho(b)$ and hence $(\mathfrak{a} + \mathfrak{b})/\mathfrak{a} \subseteq \varrho(\mathfrak{b})$ as well.
Now consider any $r \in \varrho^{-1}(\varrho(\mathfrak{b}))$ that is $\varrho(r) \in \varrho(\mathfrak{b})$. That is there is some $b \in \mathfrak{b}$ such that $r + \mathfrak{a} = \varrho(r) = \varrho(b) = b + \mathfrak{a}$. That is $r - b \in \mathfrak{a}$ and hence $r - b = a$ for some $a \in \mathfrak{a}$. In other words $r = a + b \in \mathfrak{a} + \mathfrak{b}$ which proves $\varrho^{-1}(\varrho(\mathfrak{b})) \subseteq \mathfrak{a} + \mathfrak{b}$. Conversely consider any $a \in \mathfrak{a}$ and $b \in \mathfrak{b}$. Then $\varrho(a + b) = a + b + \mathfrak{a} = b + \mathfrak{a} = \varrho(b) \in \varrho(\mathfrak{b})$ and hence $a + b \in \varrho^{-1}(\varrho(\mathfrak{b}))$. □

Proof of (1.80):

(i) By definition φ is surjective iff any $x \in S$ can be reached as $x = \varphi(a)$ for some $a \in R$. And this is just $S \subseteq \varphi(R) = \mathrm{im}(\varphi)$, or equivalently $S = \mathrm{im}(\varphi)$. And if φ is injective then there can be at most one $a \in R$ such that $\varphi(a) = 0_S$. And as $\varphi(0_R) = 0_S$ this implies $\mathrm{kn}(\varphi) = \{\, 0_R \,\}$. Conversely suppose $\mathrm{kn}(\varphi) = \{\, 0_R \,\}$ and consider $a, b \in R$ with $\varphi(a) = \varphi(b)$. Then $0_S = \varphi(a) - \varphi(b) = \varphi(a - b)$. Hence $a - b \in \mathrm{kn}(\varphi)$ such that $a - b = 0_R$ by assumption. Hence φ is injective.

(ii) The implication (a) $\implies$ (b) is clear: Just let $\Psi := \Phi^{-1}$ then we have already seen in (1.76.(iv)), that Ψ is a homomorphism of (semi-)rings again. And the converse (b) $\implies$ (a) is clear (in particular Ψ is an inverse mapping of Φ). The implication (b) $\implies$ (c) is trivial - just let $\alpha := \Psi$ and $\beta := \Psi$. And for the converse (c) $\implies$ (a) we simply compute: $\alpha = \alpha \mathbb{1}_S = \alpha(\Phi\beta) = (\alpha\Phi)\beta = \mathbb{1}_R\beta = \beta$. Thus letting $\Psi := \alpha = \beta$ we have $\Psi = \Phi^{-1}$, such that Φ is bijective.

(iii) Suppose R is a ring, then let $f := \Phi(1_R)$. If now $x \in S$ is any element then we choose $a \in R$ such that $x = \Phi(a)$. And thereby we get $fx = \Phi(1_R)\Phi(a) = \Phi(1_R a) = \Phi(a) = x$ and likewise $xf = x$. Hence $f = 1_S$ is the unit element of S and hence S is a ring, too. Further we have seen $\Phi(1_R) = 1_S$ such that Φ is a homomorphism of rings.

Suppose S is a ring, then let $e := \Phi^{-1}(1_S)$. If now $a \in R$ is any element, then $\Phi(a) = \Phi(a)1_S = \Phi(a)\Phi(e) = \Phi(ae)$ and hence $a = ae$. Likewise we see $ea = a$ and hence $e = 1_R$ is the unit element of R. Hence R is a ring, too and $\Phi(1_R) = 1_S$ is a homomorphism of rings.

(iv) Clearly the identity map $\mathbb{1}_R : R \to R : a \mapsto a$ is both, bijective and a homomorphism of (semi-)rings for any (semi-)ring $(R, +, \cdot)$. But this is nothing but the claim $\mathbb{1}_R : R \cong_{\mathrm{r}} R$. And if $\Phi : R \to S$ is an isomorphism of (semi-)rings, then Φ^{-1} is a bijective (this is clear) homomorphism of (semi-)rings again (this has already been proved). Hence the second implication. And if both $\Phi : R \cong_{\mathrm{r}} S$ and

$\Psi : S \cong_r T$ then $\Psi\Phi$ is bijective and a homomorphism of (semi-)rings (as Φ and Ψ are such). And this has been the third implication.

□

Proof of (1.83):

(i) We first need to check, that $\widetilde{\varphi}$ is well-defined: thus consider $b, c \in R$ such that $b + \mathfrak{a} = c + \mathfrak{a}$. That is $c - b \in \mathfrak{a} \subseteq \mathrm{kn}\varphi$. And hence $0 = \varphi(c-b) = \varphi(c) - \varphi(b)$ which is the well-definedness $\varphi(b) = \varphi(c)$. Now it is straightforward to see, that $\widetilde{\varphi}$ also is a homomorphism

$$\begin{aligned}
\widetilde{\varphi}\Big((b+\mathfrak{a})+(c+\mathfrak{a})\Big) &= \widetilde{\varphi}\Big((b+c)+\mathfrak{a}\Big) = \varphi(b+c) \\
&= \varphi(b)+\varphi(c) = \widetilde{\varphi}(b+\mathfrak{a})+\widetilde{\varphi}(b+\mathfrak{a}) \\
\widetilde{\varphi}\Big((b+\mathfrak{a})(c+\mathfrak{a})\Big) &= \widetilde{\varphi}\Big((bc)+\mathfrak{a}\Big) = \varphi(bc) \\
&= \varphi(b)\varphi(c) = \widetilde{\varphi}(b+\mathfrak{a})\widetilde{\varphi}(b+\mathfrak{a})
\end{aligned}$$

Thus $\widetilde{\varphi}$ always is a homomorphism of semi-rings. And if if R and S even are rings, then $R/\mathfrak{a}$ is a ring as well with the unit element $1 + \mathfrak{a}$. Thus if $\varphi(1) = 1$ is a ring-homomorphism, then $\widetilde{\varphi}(1+\mathfrak{a}) = \varphi(1) = 1$ is a ring-homomorphism, too.

(ii) Let $\mathfrak{a} := \mathrm{kn}(\varphi)$ and $\Phi := \widetilde{\varphi}$, then by (i) Φ is a well-defined (semi-)ring-homomorphism and the image of Φ certainly is the image of φ

$$\mathrm{im}(\Phi) = \Phi\left(R\big/_{\mathfrak{a}}\right) = \varphi(R) = \mathrm{im}(\varphi)$$

Hence the mapping $\Phi : R/\mathfrak{a} \to \mathrm{im}(\varphi)$ is surjective by definition. But it also is injectitve (and hence an isomorphism) due, to

$$\begin{aligned}
\varphi(a) = \varphi(b) &\iff 0 = \varphi(a) - \varphi(b) = \varphi(a-b) \\
&\iff a - b \in \mathrm{kn}(\varphi) \\
&\iff a + \mathrm{kn}(\varphi) = b + \mathrm{kn}(\varphi)
\end{aligned}$$

(iii) We will first prove that $\mathfrak{b} + R \leq_r S$ is a sub-ring of S: clearly we have $0 = 0 + 0 \in \mathfrak{b} + R$ and (if R is a sub-ring of S) $1 = 0 + 1 \in \mathfrak{b} + R$. Now let $b + a$ and $d + c \in \mathfrak{b} + R$, then

$$\begin{aligned}
(b+a)+(d+a) &= (b+d)+(a+c) \in \mathfrak{b}+R \\
-(b+a) &= (-b)+(-a) \in \mathfrak{b}+R \\
(b+a)(d+c) &= (bd+bc+ad)+ac \in \mathfrak{b}+R
\end{aligned}$$

And hence $\mathfrak{b} + R$ is a sub-ring of S. And as $\mathfrak{b} \trianglelefteq_i R$ is an ideal of S with $\mathfrak{b} \subseteq \mathfrak{b} + R$ it trivially also is an ideal $\mathfrak{b} \trianglelefteq_i \mathfrak{b} + R$. Now let us denote the restriction of the canonical epimorphism $\sigma : S \to S/\mathfrak{b}$ to R by

$$\varrho : R \to S\big/_{\mathfrak{b}} : a \mapsto a + \mathfrak{b}$$

Then ϱ is a homomorphism with kernel $\mathrm{kn}(\varrho) = \mathrm{kn}(\sigma) \cap R = \mathfrak{b} \cap R$. In particular this proves that $\mathfrak{b} \cap R \trianglelefteq_i R$ is an ideal of R (as it is the kernel of a homomorphism). And it is straightforward to

see, that $\mathrm{im}(\varphi) = (\mathfrak{b}+R)/\mathfrak{b}$. [For any $a \in R$ we have $a \in \mathfrak{b}+R$ and hence $\varrho(a) \in (\mathfrak{b}+R)/\mathfrak{b}$. And if conversely $x = b+a \in \mathfrak{b}+R$ then $\varrho(a) = a+\mathfrak{b} = x+\mathfrak{b}$]. Thus we may apply the first isomorphism theorem (ii) to obtain

$$\begin{array}{rcccl} R\big/_{\mathrm{kn}(\varrho)} & = & R\big/_{\mathfrak{b}\cap R} & \cong_{\mathsf{r}} & \mathrm{im}(\varrho) \;=\; \mathfrak{b}+R\big/_{\mathfrak{b}} \\ & & a+\mathfrak{b}\cap R & \mapsto & \varrho(a) \;=\; a+\mathfrak{b} \end{array}$$

(iv) Suppose c and $d \in R$ with $c+\mathfrak{a} = d+\mathfrak{a}$. Then $c-d \in \mathfrak{a} \subseteq \mathfrak{b}$ and hence $c+\mathfrak{b} = d+\mathfrak{b}$. Therfore we may define the following mapping (which clearly is a homomorphism of (semi-)rings)

$$\varphi \;:\; R\big/_{\mathfrak{a}} \to R\big/_{\mathfrak{b}} \;:\; c+\mathfrak{a} \mapsto c+\mathfrak{b}$$

And clearly $\mathrm{kn}(\varphi) = \{\, b+\mathfrak{a} \mid b+\mathfrak{b} = 0+\mathfrak{b} \,\} = \{\, b+\mathfrak{a} \mid b \in \mathfrak{b} \,\} = \mathfrak{b}/\mathfrak{a}$. Hence we immediately obtain (iv) from the first isomorphism theorem.

□

Proof of (1.85):

(i) Let C denote the intersection $C = \{\, a \in R \mid \forall\, i \in I \;:\; a \in C_i \,\}$, then it is clear that $0,\, 1 \in C$, as any C_i is a positive cone and hence $0,\, 1 \in C_i$. Likewise, if $a,\, b \in C$ then for any $i \in I$ we have $a,\, b \in C_i$ and hence $a+b \in C_i$ and $a \cdot b \in C_i$, as C_i was supposed to be a positive cone. Yet this again means $a+b \in C$ and $a \cdot b \in C$, such that C is a positive cone again.

(ii) It remains to show, that $\mathrm{cone}(A)$ is well-defined. However, as R itself is a positive cone and $C \subseteq R$, hence R is an element of the defining set $\{\, C \subseteq R \mid A \subseteq C,\, C \text{ is a positive cone} \,\}$. In particular this set is non-empty and hence the intersection over all its elements exists.

(iii) Recall the definitions of the image $\varphi(C) = \{\, \varphi(a) \mid a \in C \,\}$ and the preimage $\varphi^{-1}(D) = \{\, a \in R \mid \varphi(a) \in D \,\}$. Now, as $0 = \varphi(0)$ and $1 = \varphi(1)$ we get both $0,\, 1 \in \varphi(C)$ and $0,\, 1 \in \varphi^{-1}(D)$.

So given any $u,\, v \in \varphi(C)$ there are some $a,\, b \in C$ such that $u = \varphi(a)$ and $v = \varphi(b)$. Thereby $u+v = \varphi(a)+\varphi(b) = \varphi(a+b) \in \varphi(C)$ and likewise $u \cdot v = \varphi(a) \cdot \varphi(b) = \varphi(a \cdot b) \in \varphi(C)$ again. Altogether this means that $\varphi(C)$ is a positive cone again.

Similarly, if $a,\, b \in \varphi^{-1}(D)$ we have $\varphi(a),\, \varphi(b) \in D$ and therefore $\varphi(a+b) = \varphi(a)+\varphi(b) \in D$ which implies $a+b \in \varphi^{-1}(D)$. In complete analogy we find $\varphi(a \cdot b) = \varphi(a) \cdot \varphi(b) \in D$ and hence $a \cdot b \in \varphi^{-1}(D)$. □

Proof of (1.86):

In (i) to (iv) there is nothing to prove - everything is either trivial or well-known. But we wish to give a short prove for (v): First of all, we have $0 \leq 0$ due to the reflexivity (O1) of $\leq$. Furthermore $0 \leq 1$ is property (P1) of $\leq$. Thereby $0,\, 1 \in R^+$. If now $a,\, b \in R^+$, then $0 \leq a$ and $0 \leq b$ and hence $0 \leq a+b$ and $0 \leq a \cdot b$ due to properties (P3) and (P4). But this again means $a+b$ and $a \cdot b \in R^+$ such that R^+ is a positive cone. Suppose $a \in R^+ \cap (-R^+)$ that is $0 \leq a$ and $0 \leq -a$. The latter is $0 \leq 0-a$ and hence $a \leq 0$ due to (P2). But as also $0 \leq a$ the anti-symmetry (O2) implies $a = 0$.

Claim number (vi) is fairly easy to see: first of all $0 = 0^2$ and $1 = 1^2$ such that $0, 1 \in \Delta$ is satisfied. Property (C2) of cones is satisfied trivially and for property (C3) we have to regard $a = a_1^2 + \cdots + a_m^2$ and $b = b_1^2 + \cdots + b_n^2 \in \Delta$. Then it is clear that also $ab \in \Delta$, as

$$ab \;=\; \sum_{i=1}^{m}\sum_{j=1}^{n} a_i^2 b_j^2 \;=\; \sum_{(i,j)=(1,1)}^{(m,n)} (a_i b_j)^2$$

We will now prove (vii) that $R[x]^+$ is a proper cone: As $0 \in R^+$ and $\mathrm{lc}(0) = 0$ we get $0 \in R[x]^+$ as well. Likewise $1 \in R[x]^+$. If now f and g are two polynomials in $R[x]^+$ then we have to show that $f+g$ and $f \cdot g$ are in $R[x]^+$ again. If one of them - say $f = 0$ - then $f + g = g$ and $f \cdot g = 0$ and hence there is nothing to prove. Otherwise let

$$\begin{aligned} f(x) &= a_m x^m + \cdots + a_k x^k \\ g(x) &= b_n x^n + \cdots + b_l x^l \end{aligned}$$

By assumption $f, g \in R[x]^+$ we have a_m and $b_n \geq 0$. Therefore, if $m = n$ then $\mathrm{lc}(f+g) = a_n + b_n \geq 0$. And if $m \neq n$, say $m < n$ then $\mathrm{lc}(f+g) = b_n \geq 0$. In any case we get $\mathrm{lc}(f+g) \geq 0$ and hence $f + g \in R[x]^+$ again. Also by definition of the multiplication in $R[x]$ we have

$$(f \cdot g)(x) \;=\; \sum_{u=0}^{\infty} \left(\sum_{p+q=u} f[p] \cdot g[q] \right) x^u$$

Thus if $u > m + n$ then either $p > m$ or $q = u - p > n$, in any case we have $f[p] \cdot g[q] = 0$. And for the same reason all combinations (p, q) with $p + q = u$ for $u = m + n$ yield $f[p] \cdot g[q] = 0$ except $f[m] \cdot g[n] = a_m \cdot b_n \neq 0$, as R is an integral domain. Hence $\mathrm{lc}(f \cdot g) = a_m \cdot b_n$ and as both have been positive, so is $\mathrm{lc}(f \cdot g) \geq 0$. And this again means $f \cdot g \in R[x]^+$ such that $R[x]^+$ is a positive cone as well. To prove that $R[x]^+$ is proper consider some $f \in R[x]$ such that $f \in R[x]^+$ and $-f \in R[x]^+$. Let $a := \mathrm{lc}(f)$ then this means $a \geq 0$ and $-a \geq 0$. But due to (v) this implies $a = 0$ (see above). And the only polynomial with $\mathrm{lc}(f) = 0$ is $f = 0$.
In complete analogy to the arguments above one can show that $R[x]^-$ is a proper, positive cone of $R[x]$, as well. □

Proof of (1.89):

(i) If $a \geq 0$ then $|a| = a \geq 0$ is clear. Otherwise, if $a \leq 0$ then $|a| = -a$ but as $a \leq 0$ (P6) implies $-a \geq 0$ and hence $|a| \geq 0$.

(ii) If $a \geq 0$ then $|a| = a \geq a$ is clear. Otherwise, if $a \leq 0$ then $|a| = -a$ but as $a \leq 0$ (P6) implies $-a \geq 0 \geq a$ and hence $|a| \geq a$.

(iii) If $a \geq 0$ then $|a| = a$ and hence $|a|^2 = a^2$ is clear. Otherwise, if $a \leq 0$ then $|a| = -a$ such that $|a|^2 = (-a)^2 = a^2$ again.

(iv) We have to consider three cases: (1) if $a > 0$ then $|a| = a$ and $\mathrm{sgn}(a) = 1$ such that $|a| = a = 1 \cdot a = \mathrm{sgn}(a)a$. (2) if $a = 0$, then $|a| = 0$ and $\mathrm{sgn}(a) = 0$ such that $|a| = 0 = 0 \cdot 0 = \mathrm{sgn}(a)a$. (3) lastly, if $a < 0$ then $|a| = -a$ and $\mathrm{sgn}(a) = -1$ such that $|a| = -a = (-1) \cdot a = \mathrm{sgn}(a)a$. Thus the equality holds true in any of these three cases.

(ix) If $a \leq b$ then (as $0 \leq a$) we get $a^2 \leq ab$ due to (P8). Likewise (as $0 \leq b$ as well) we find $ab \leq b^2$. Thus $a^2 \leq ab \leq b^2$ which implies $a^2 \leq b^2$ due to the transitivity of $\leq$. Conversely we start with $a^2 \leq b^2$. Suppose we had $a > b$ then in particular $b \leq a$ such that $b^2 \leq a^2 \leq b^2$. This implies $a^2 = b^2$ and hence $0 = b^2 - a^2 = (a-b)(a+b)$. As R is an integral domain this would mean $a = b$ (in contradiction to $a > b$) or $a + b = 0$. But again $0 \leq a = -b \leq 0$ implies $a = b = 0$ in contradiction to $a > b$. Thus $a > b$ is false, which only leaves $a \leq b$.

(viii) If $a = 0$ or $b = 0$ then $ab = 0$ and hence $\operatorname{sgn}(ab) = 0 = \operatorname{sgn}(a)\operatorname{sgn}(b)$. Now suppose $a \neq 0$ and $b \neq 0$ and distinguish 4 cases: (1) if $a > 0$ and $b > 0$ then $ab > 0$ due to (P4) and hence $\operatorname{sgn}(ab) = 1 = 1 \cdot 1 = \operatorname{sgn}(a)\operatorname{sgn}(b)$. (2) if $0 < a$ and $b < 0$ then $0 > ab$ due to (P9) such that $\operatorname{sgn}(ab) = -1 = 1 \cdot (-1) = \operatorname{sgn}(a)\operatorname{sgn}(b)$. (3) the case $a < 0$ and $b > 0$ is completely analogous to case (2), by flipping a and b. (4) if $a < 0$ and $b < 0$ then $-a > 0$ and $-b > 0$. Now by (1) we get $\operatorname{sgn}(ab) = \operatorname{sgn}((-a)(-b)) = 1 = (-1)(-1) = \operatorname{sgn}(a)\operatorname{sgn}(b)$. Thus the equality holds true in any of these cases.

(v) Once (iv) and (viii) have been established this is straightforward: $|ab| = \operatorname{sgn}(ab)ab = \operatorname{sgn}(a)a \cdot \operatorname{sgn}(b)b = |a| \cdot |b|$.

(vi) Due to (iii) we know $|a+b|^2 = (a+b)^2 = a^2 + 2ab + b^2$. But according to (ii) $ab \leq |ab|$ such that $|a+b|^2 = a^2 + 2ab + b^2 \leq a^2 + 2|ab| + b^2$. We now invoke (v) and (iii) again to find $|a+b|^2 \leq a^2 + 2|ab| + b^2 = |a|^2 + 2|a||b| + |b|^2 = (|a| + |b|)^2$. As both $|a|$ and $|b| \geq 0$ we can finally use (ix) to deduce $|a+b| \leq |a| + |b|$ as claimed.

(vii) First of all $|a| = |b + (a-b)| \leq |b| + |a-b|$ according to (vi). And from this we get $|a| - |b| \leq |a-b|$. Now in complete analogy we have $|b| = |a + (b-a)| \leq |a| + |b-a|$ and hence $-(|a| - |b|) = |b| - |a| \leq |b-a| = |a-b|$. Combining these two cases we see $||a| - |b|| \leq |a-b|$.

□

Proof of (1.91):
First of all for any $a \in R$ we have $a - a = 0 \in C$ and hence (O1). Also if $a \leq b$ and $b \leq c$ this means $b - a$ and $c - b \in C$ and hence $c - a = (c-b) + (b-a) \in C$ such that (O2). In particular, if $a \leq b$ and $b \leq a$ that $b - a$ and $-(b-a) = a - b \in C$, but as C is proper this means $b - a = 0$ and hence (O3). As $1 \in C$ we have $0 \leq 1$ which is (P1), (P2) is satisfied trivially: $a \leq b \iff b - a \in C \iff (b-a) - 0 \in C \iff 0 \leq b - a$. And at last, for any a and $b \in R$ with $0 \leq a$ and $0 \leq b$ we have a, $b \in C$ such that $a + b$ and $ab \in C$ which again means $a + b$ resp. $ab \geq 0$. □

Proof of (1.92):
We have already proved that: given a proper positive cone C we can define a positive order $a \leq b$ by letting $b - a \in C$. And conversely, if $\leq$ is a positive order on R, then $R^+ = \{\, a \in R \mid a \geq 0 \,\}$ is a proper positive cone in R. Hence both of these maps are well-defined. It remains to show that they also are mutually inverse.
Let us first start with a proper positive cone C, then we have to show that $R^+ = C$. By definition $a \geq 0$ means $a - 0 = a \in C$, so this is true already. Conversely, given a positive order $\leq$ we have to show that $a \leq b$ is equivalent to $b - a \in R^+$. But by definition this is $b - a \geq 0$ such that this is guaranteed by property (P2) of positive orders. □

Proof of (1.93):
A word in advance: we have $N = R^+ \cap \mathrm{NZD}(R)$. It is well known (and easy to see) that the set $\mathrm{NZD}(R)$ of non-zero divisors of R is multiplicatively closed. And R^+ is multiplicatively closed due to (1) and (4). Hence N is multiplicatively closed, as an intersection of such sets.
To begin with we have to prove the well-definedness of the relation. Thus we consider $a/m = a'/m'$ and $b/n = b'/n'$. That is $u(am' - a'm) = 0$ for some $u \in N$. In particular u is a non-zero divisor and hence $am' = a'm$. Likewise $bn' = b'n$. We now have to show that $a'/m' \leq b'/n'$ implies (and by universality hence already is equivalent to) $a/m \leq b/n$. By definition

$$\frac{a'}{m'} \leq \frac{b'}{n'} \iff a'n' \leq b'm' \iff 0 \leq b'm' - a'n'$$

Multiplying the latter inequality with $mn \geq 0$ we get $0 \leq mn(b'm' - a'n') = b'nmm' - a'mnn' = bn'mm' - am'nn'$. This again yields $am'nn' \leq bn'mm'$, which once again iturns into

$$a(nm'n') \leq (bm'n')m \iff \frac{a}{m} \leq \frac{bm'n'}{nm'n'} = \frac{b}{n}$$

Thus we truly got $a/m \leq b/n$ and hence the well-definedness of $\leq$. In a next step we have to prove that this relation also is a partial order. The *reflexivity* $a/m \leq a/m$ is clear, as $am \leq am$. The *anti-symmetry* is easy as well: consider $a/m \leq b/n$ such that $a/m \leq b/n$ as well. This means $an \leq bm$ and $bm \leq an$ such that $an = bm$. This again is $a/m = b/n$. It remains to verify the *transitivity*: consider $a/m \leq b/n$ and $b/n \leq c/u$. That is $an \leq bm$ and $bu \leq cn$. As u and $m \geq 0$ we find $aun \leq bum$ and $bum \leq cnm$ such that $aun \leq cnm$. This again yields $a/m \leq (cn)/(un) = c/u$.
Now we're ready for the actual topic of the claim: the *positivity* of the partial order $\leq$. First note that by definition we have

$$0 \leq \frac{b}{n} \iff 0 \leq b$$

Thereby property (1) is obvious, as $0/1 \leq 1/1 \iff 0 \leq 1$. And for (2) we consider $a/m \leq b/n$, which is $an \leq bm$ and hence $0 \leq bm - an$. As we have just seen this is $0 \leq (bm - an)/(mn) = b/n - a/m$, such that the equivalence is established. For properties (3) and (4) we are given a/m and $b/n \geq 0$. That is a, $b \geq 0$, hence $ab \geq 0$ and thus $(a/m)(b/n) = (ab)/(mn) \geq 0$. Likewise (as m, $n \geq 0$ as well) we have $an + bm \geq 0$ such that $a/m + b/n = (an + bm)/(mn) \geq 0$. □

Proof of (1.97):

(1) We will first prove that $\mathfrak{a} \oplus \mathfrak{b} \trianglelefteq_{\mathrm{i}} R \oplus S$ is an ideal. As $\mathfrak{a}$ and $\mathfrak{b}$ are ideals we have $0 \in \mathfrak{a}$ and $0 \in \mathfrak{b}$ and hence $0 = (0,0) \in \mathfrak{a} \oplus \mathfrak{b}$. Now consider (a,b) and $(p,q) \in \mathfrak{a} \oplus \mathfrak{b}$. Then we have $a + p \in \mathfrak{a}$, $b + q \in \mathfrak{b}$ and hence $(a,b) + (p,q) = (a + p, b + q) \in \mathfrak{a} \oplus \mathfrak{b}$. Finally consider any $(r,s) \in R \oplus S$ then $ra \in \mathfrak{a}$ and $sb \in \mathfrak{b}$ such that $(r,s)(a,b) = (ra,sb) \in \mathfrak{a} \oplus \mathfrak{b}$ again. And as R and S are commutative rings, so is $R \oplus S$ such that this has been enough to guarantee that $\mathfrak{a} \oplus \mathfrak{b}$ is an ideal of $R \oplus S$.

(2) Next we will prove $\mathfrak{u} = \varrho(\mathfrak{u}) \oplus \sigma(\mathfrak{u})$. If $(a,b) \in \mathfrak{u}$ then it is clear that $a = \varrho(a,b) \in \varrho(\mathfrak{u})$ and $b = \sigma(a,b) \in \sigma(\mathfrak{u})$ such that $(a,b) \in \varrho(\mathfrak{u}) \oplus \sigma(\mathfrak{u})$. Conversely if $(a,b) \in \varrho(\mathfrak{u}) \oplus \sigma(\mathfrak{u})$ then there are some $r \in R$ and $s \in S$ such that $(a,s) \in \mathfrak{u}$ and $(r,b) \in \mathfrak{u}$. But as $\mathfrak{u}$ is an ideal we also have $(a,0) = (1,0)(a,s) \in \mathfrak{u}$ again and analogously $(0,b) \in \mathfrak{u}$. Thererby $(a,b) = (a,0) + (0,b) \in \mathfrak{u}$ proving the equality.

(3) Now we are ready to prove $\mathrm{Ideal}(R) \oplus S = \{\mathfrak{a} \oplus \mathfrak{b} \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} R,\ \mathfrak{b} \trianglelefteq_{\mathrm{i}} S\}$. We have already seen in (1) that $\mathfrak{a} \oplus \mathfrak{b}$ is an ideal of $R \oplus S$ (supposed $\mathfrak{a}$ and $\mathfrak{b}$ are ideals). Conversely if $\mathfrak{u} \trianglelefteq_{\mathrm{i}} R \oplus S$ is an ideal, then we let $\mathfrak{a} := \varrho(\mathfrak{u})$ and $\mathfrak{b} := \sigma(\mathfrak{u})$. Then $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ and $\mathfrak{b} \trianglelefteq_{\mathrm{i}} S$ are ideals, since ϱ and σ are surjective homomorphisms. And $\mathfrak{u} = \mathfrak{a} \oplus \mathfrak{b}$ by (2).

(4) Now let $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ and $\mathfrak{b} \trianglelefteq_{\mathrm{i}} S$. Then we will prove $\sqrt{\mathfrak{a} \oplus \mathfrak{b}} = \sqrt{\mathfrak{a}} \oplus \sqrt{\mathfrak{b}}$. First suppose that $(a,b)^k = (a^k, b^k) \in \mathfrak{a} \oplus \mathfrak{b}$ for some $k \in \mathbb{N}$. Then $a^k \in \mathfrak{a}$ and $b^k \in \mathfrak{b}$ such that $a \in \sqrt{\mathfrak{a}}$ and $b \in \sqrt{\mathfrak{b}}$ and thereby $(a,b) \in \sqrt{\mathfrak{a}} \oplus \sqrt{\mathfrak{b}}$. Conversely suppose $a^k \in \mathfrak{a}$ and $b^l \in \mathfrak{b}$ for some $k, l \in \mathbb{N}$. Then we define $n := \max\{k,l\}$ and thereby get $(a,b)^n = (a^n, b^n) \in \mathfrak{a} \oplus \mathfrak{b}$. And this means that (a,b) is contained in the radical of $\mathfrak{a} \oplus \mathfrak{b}$ again.

(5) This enables us to prove $\mathrm{Srad}(R) \oplus S = \{\mathfrak{a} \oplus \mathfrak{b} \mid \mathfrak{a} = \sqrt{\mathfrak{a}},\ \mathfrak{b} = \sqrt{\mathfrak{b}}\}$. First suppose that $\mathfrak{u} \trianglelefteq_{\mathrm{i}} R \oplus S$ is a radical ideal and let $\mathfrak{a} := \varrho(\mathfrak{u})$ and $\mathfrak{b} := \sigma(\mathfrak{u})$ again. Then by (4) we may compute

$$\mathfrak{a} \oplus \mathfrak{b} \;=\; \mathfrak{u} \;=\; \sqrt{\mathfrak{u}} \;=\; \sqrt{\mathfrak{a} \oplus \mathfrak{b}} \;=\; \sqrt{\mathfrak{a}} \oplus \sqrt{\mathfrak{b}}$$

This proves that $\mathfrak{a} = \sqrt{\mathfrak{a}}$ and $\mathfrak{b} = \sqrt{\mathfrak{b}}$ are radical ideals of R and S respectively. And if conversely $\mathfrak{a}$ and $\mathfrak{b}$ are radical ideals then $\mathfrak{a} \oplus \mathfrak{b}$ is a radical ideal of $R \oplus S$ by virtue of

$$\mathfrak{a} \oplus \mathfrak{b} \;=\; \sqrt{\mathfrak{a}} \oplus \sqrt{\mathfrak{b}} \;=\; \sqrt{\mathfrak{a} \oplus \mathfrak{b}}$$

(6) Next we will prove $\mathrm{Spec}(R) \oplus S = \{\mathfrak{p} \oplus S\} \cup \{R \oplus \mathfrak{q}\}$. If $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ is a prime ideal then we have already proved $\mathfrak{p} \oplus S \trianglelefteq_{\mathrm{i}} R \oplus S$ in (1). And it is clear that $\mathfrak{p} \oplus S \neq R \oplus S$ as $(1,0) \notin \mathfrak{p} \oplus S$. Thus suppose $(a,b)(p,q) = (ap, bq) \in \mathfrak{p} \oplus S$. Then $ap \in \mathfrak{p}$ and as $\mathfrak{p}$ is prime this means $a \in \mathfrak{p}$ or $p \in \mathfrak{p}$. Without loss of generality we may take $p \in \mathfrak{p}$ and thereby $(p,q) \in \mathfrak{p} \oplus S$. Altogether we have seen that $\mathfrak{p} \oplus S$ is a prime ideal of $R \oplus S$. And analogously one may prove that $R \oplus \mathfrak{q}$ is prime, supposed $\mathfrak{q} \trianglelefteq_{\mathrm{i}} S$ is prime. Thus conversely consider a prime ideal $\mathfrak{u} \trianglelefteq_{\mathrm{i}} R \oplus S$ let $\mathfrak{p} := \varrho(\mathfrak{u})$ and $\mathfrak{q} := \sigma(\mathfrak{u})$. Clearly $(1,0)(0,1) = (0,0) \in \mathfrak{u}$. And as $\mathfrak{u}$ is prime this means $(1,0) \in \mathfrak{u}$ or $(0,1) \in \mathfrak{u}$. We will assume $(0,1) \in \mathfrak{u}$, as the other case can be dealt with in complete analogy. Then $1 \in \mathfrak{q}$ and hence $\mathfrak{q} = S$. That is $\mathfrak{u} = \mathfrak{p} \oplus S$ and as $\mathfrak{u} \neq R \oplus S$ this means $\mathfrak{p} \neq R$. Thus consider a and $p \in R$ such that $ap \in \mathfrak{p}$. Then $(a,0)(p,0) = (ap,0) \in \mathfrak{p} \oplus S = \mathfrak{u}$. And as $\mathfrak{u}$ is prime this means $(a,0) \in \mathfrak{u}$ or $(p,0) \in \mathfrak{u}$ (which we assume w.l.o.g.). Thereby $p \in \mathfrak{p}$, altogether we have found that $\mathfrak{u} = \mathfrak{p} \oplus S$ for some prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$.

(7) It remains to prove $\mathrm{Smax}(R) \oplus S = \{\mathfrak{m} \oplus S\} \cup \{R \oplus \mathfrak{n}\}$. Thus consider a maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ and suppose $\mathfrak{m} \oplus S \subseteq \mathfrak{u} \trianglelefteq_{\mathrm{i}} R \oplus S$. Then $S = \sigma(\mathfrak{m} \oplus S) \subseteq \mathfrak{b} := \sigma(\mathfrak{u}) \trianglelefteq_{\mathrm{i}} S$ and hence $\mathfrak{b} = S$. Likewise we find $\mathfrak{m} = \varrho(\mathfrak{m} \oplus S) \subseteq \mathfrak{a} := \varrho(\mathfrak{u}) \trianglelefteq_{\mathrm{i}} R$ and as $\mathfrak{m}$ is maximal this implies $\mathfrak{a} = \mathfrak{m}$ or $\mathfrak{a} = R$. Thus we get $\mathfrak{u} = \mathfrak{a} \oplus \mathfrak{b} = \mathfrak{m} \oplus S$ or $\mathfrak{u} = \mathfrak{a} \oplus \mathfrak{b} = R \oplus S$. And this means that $\mathfrak{m} \oplus S$ is a maximal ideal of $R \oplus S$. Likewise one can see that $R \oplus \mathfrak{n}$ is a maximal ideal for any $\mathfrak{n} \trianglelefteq_{\mathrm{i}} S$ maximal. Conversely consider a maximal ideal $\mathfrak{u} \trianglelefteq_{\mathrm{i}} R \oplus S$. In particular $\mathfrak{u}$ is prime and hence - by (6) - $\mathfrak{u} = \mathfrak{m} \oplus S$ or $\mathfrak{u} = R \oplus \mathfrak{n}$ for some prime ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ or $\mathfrak{n} \trianglelefteq_{\mathrm{i}} S$ respectively. We only regard the case $\mathfrak{u} = \mathfrak{m} \oplus S$ again, as the other is completely analogous. Thus consider some ideal $\mathfrak{m} \subseteq \mathfrak{a} \trianglelefteq_{\mathrm{i}} R$, then $\mathfrak{u} = \mathfrak{m} \oplus S \subseteq \mathfrak{a} \oplus S \trianglelefteq_{\mathrm{i}} R \oplus S$. By maximality of $\mathfrak{u}$ that is $\mathfrak{u} = \mathfrak{m} \oplus S = \mathfrak{a} \oplus S$ or $\mathfrak{a} \oplus S = R \oplus S$. Again this yields $\mathfrak{m} = \mathfrak{a}$ or $\mathfrak{a} = R$ and this means that $\mathfrak{m}$ is maximal.

□

Proof of (1.99):

(i) From $1 = e + f \in \mathfrak{a} + \mathfrak{b} \trianglelefteq_{\mathfrak{i}} R$ it is clear that $\mathfrak{a} + \mathfrak{b} = R$. Now consider any $x \in \mathfrak{a} \cap \mathfrak{b}$. That is there are a and $b \in R$ such that $x = ae = bf$. Then we get $xe = (bf)e = b(fe) = 0$ and $xf = (ae)f = a(ef) = 0$. And thereby $x = x1 = x(e + f) = xe + xf = 0$ such that $\mathfrak{a} \cap \mathfrak{b} = \{0\}$.

(ii) For any $a \in R$ we have $a = a1 = a(e_1 + \cdots + e_n) = ae_1 + \cdots + ae_n \in \mathfrak{a}_1 + \cdots + \mathfrak{a}_n$. Thus we have $R \subseteq \mathfrak{a}_1 + \cdots + \mathfrak{a}_n$ and the converse inclusion is clear, as all the $\mathfrak{a}_k$ are ideals of R. That is property (1). For (2) we consider any $x \in \mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_n$. That is for any $i \in 1 \ldots n$ there is some $a_i \in R$, such that $x = a_i e_i$. Thus for any $j \neq i$ we get $xe_j = (ae_i)e_j = a(e_i e_j) = 0$. As $n \geq 2$ we may choose $xe_1 = (a_2 e_2)e_1 = 0$ and for any $j \geq 2$ likewise $xe_j = (a_1 e_1)e_j = 0$. Thereby we find $x = x1 = x(e_1 + \cdots + e_n) = xe_1 + \cdots + xe_n = 0$. That is property (2).

(iii) It is clear that $\Phi : x \mapsto (x + \mathfrak{a}, x + \mathfrak{b})$ is a well-defined homomorphism of rings (as it fibers into the canonical epimorphisms $x \mapsto x + \mathfrak{a}$ and $x \mapsto x + \mathfrak{b}$). Now suppose $(x + \mathfrak{a}, x + \mathfrak{b}) = \Phi(x) = 0 = (0 + \mathfrak{a}, 0 + \mathfrak{b})$. This means $x \in \mathfrak{a}$ and $x \in \mathfrak{b}$ and hence $x \in \mathfrak{a} \cap \mathfrak{b} = \{0\}$. Thus we have $x = 0$ which implies $\mathrm{kn}(\Phi) = \{0\}$, which means that Φ is injective. It remains to prove, that Φ also is surjective: Since $\mathfrak{a} + \mathfrak{b} = R$ there are some $e \in \mathfrak{a}$ and $f \in \mathfrak{b}$ such that $e + f = 1$. Now suppose we are given any $(y + \mathfrak{a}, z + \mathfrak{b})$. Then let $x := yf + ze$ and compute

$$\begin{aligned}
\Phi(x) &= (yf + ze + \mathfrak{a}, yf + ze + \mathfrak{b}) \\
&= (yf + \mathfrak{a}, ze + \mathfrak{b}) \\
&= (yf + ye + \mathfrak{a}, ze + zf + \mathfrak{b}) \\
&= (y(f + e) + \mathfrak{a}, z(e + f) + \mathfrak{b}) \\
&= (y + \mathfrak{a}, z + \mathfrak{b})
\end{aligned}$$

(iv) We will now prove the Chinese remainder theorem in several steps. (1) Let us first consider the following homomorphism of rings

$$\varphi \ : \ R \to \bigoplus_{i=1}^{n} R \Big/ \mathfrak{a}_i \ : \ x \mapsto (x + \mathfrak{a}_i)$$

We now compute the kernel of φ: $\varphi(x) = 0 = (0 + \mathfrak{a}_i)$ holds true if and only if for any $i \in 1 \ldots n$ we have $x + \mathfrak{a}_i = 0 + \mathfrak{a}_i$. And of course this is equivalent, to $x \in \mathfrak{a}_i$ for any $i \in 1 \ldots n$. And again this can be put as $x \in \mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_n$. Hence we found $\mathrm{kn}(\varphi) = \mathfrak{a}$. Now we aim for the surjectivity of φ: (2) As a first approach we prove the existence of a solution $x \in R$ of the system $\varphi(x) = (1 + \mathfrak{a}_1, 0 + \mathfrak{a}_2, \ldots, 0 + \mathfrak{a}_n)$. Since $\mathfrak{a}_1 + \mathfrak{a}_j = R$ for any $j \in 2 \ldots n$ we also find $\mathfrak{a}_1 + \mathfrak{a}_2 \ldots \mathfrak{a}_n = R$ due to (1.61.(iii)). That is there are elements $e_1 \in \mathfrak{a}_1$ and $f_1 \in \mathfrak{a}_2 \ldots \mathfrak{a}_n$ such that $e_1 + f_1 = 1$. Hence we find $f_1 + \mathfrak{a}_j = 0 + \mathfrak{a}_j$ for any $j \in 2 \ldots n$. And also $f_1 + \mathfrak{a}_1 = (1 - e_1) + \mathfrak{a}_1 = 1 + \mathfrak{a}_1$. That is $x := f_1$ does the trick. (3) Analogous to (2) we find $f_2, \ldots, f_n \in R$ such that for any $j \in 1 \ldots n$ we obtain the system

$$\varphi(f_j) \ = \ (\delta_{i,j} + \mathfrak{a}_i)$$

(4) Thus if we are now given any $a_1, \ldots, a_n \in R$ then we let us define $x := a_1 f_1 + \cdots + a_n f_n$ and

we thereby obtain

$$x + \mathfrak{a}_i \;=\; \sum_{j=1}^{n} a_j f_j + \mathfrak{a}_i \;=\; \sum_{j=1}^{n} a_j \delta_{i,j} + \mathfrak{a}_i \;=\; a_j + \mathfrak{a}_i$$

Hence $\varphi(x) = (a_i + \mathfrak{a}_i)$ and as the a_i have been arbitrary this means that φ is surjective. (5) Thus (1.83.(ii)) yields the desired isomorphy.

□

15.3 Proofs of Chapter 2

Proof of (2.1):

(v) As $\leq$ is a total order, we may assume $a \leq b$ without loss of generality. If $a, b \in A^*$, then $b \in A$, $a \leq b$ and $a \in A^*$ implies $a = b$. Likewise if $a, b \in A_*$ then $a \in A$, $a \leq b$ and $a \in A_*$ implies $a = b$.

(vi) By induction on n: if $n = 1$ then $a_* = a_1$ is trivial and if $n = 2$ then a_* is minimal by construction. Thus for $n \geq 3$ we let $H := \{ a_1, \ldots, a_{n-1} \} \subseteq A$. By induction hypothesis we have $H_* = \{ h_* \}$ for $h^* = ((a_1 \wedge a_2) \ldots) \wedge a_{n-1}$. Now let $a_* := h_* \wedge a_n$ then $a_* \leq h_* \leq a_i$ for $i < n$ and $a_* \leq a_n$ by construction. Hence we have $a_* \leq a_i$ for any $i \in 1 \ldots n$, which means $a_* \in A_*$. And the uniqueness has already been shown above. This also proves the like statement for A^* by taking to the inverse ordering $b \geq a \ :\Longleftrightarrow \ a \leq b$.

(ix) Regard $\mathcal{Z}$ as a partially ordered set $(\mathcal{Z}, \subseteq)$ under the inclusion relation (this is allowed, due to (1)). If now $\mathcal{C} \subseteq \mathcal{Z}$ is a chain, then by (2) we get $U := \bigcup \mathcal{C} \in \mathcal{Z}$. And clearly we have $C \subseteq U$ for any $C \in \mathcal{C}$. Thus U is an upper bound of $\mathcal{C}$ and hence we may apply the lemma of Zorn to $(\mathcal{Z}, \subseteq)$, to find a maximal element $Z \in \mathcal{Z}^*$.

(x) Let us define the partial order $B \leq A \ :\Longleftrightarrow \ A \subseteq B$ on $\mathcal{Z}$. If now $\mathcal{C} \subseteq \mathcal{Z}$ is a chain, then by (2) we get $U := \bigcap \mathcal{C} \in \mathcal{Z}$. And clearly $U \subseteq C$ (which translates into $C \leq U$) for any $C \in \mathcal{C}$. Thus U is an upper bound of $\mathcal{C}$ and hence we may apply the lemma of Zorn to find a $\leq$-maximal element Z. But being $\leq$-maximal trivially translates into being $\subseteq$-minimal again.

□

Proof of (2.67):
Existence: Let us abbreviate $m := \deg(f)$ and $n := \deg(g)$. If $n < m$ then we may take $q = 0$ and $r = g$ and are done already. Thus throughout this proof we may assume $m \leq n$. We will now use induction on n: In case $n = 0$ we have $g = g[0] \in R$ and since $m \leq n = 0$ also $f = f[0] = 1$. Thus the claim is trivially satisfied, with $r = 0$ and $q = g[0]$, since

$$g \ = \ g[0] \ = \ g[0] \cdot 1 + 0 \ = \ qf + r$$

So let us now assume, we had some q and r as required for any polynomial of degree up to $n-1$. Then we need to find sufficient polynomials for g of degree n. To find these let

$$p \ := \ g[n] t^{n-m} \ \in \ R[t]$$

Then it is clear that $\deg(g - pf) < n$ since

$$\begin{aligned} g - pf &= \sum_{k=0}^{n} g[k] t^k - g[n] t^{n-m} \left(t^m + \sum_{k=0}^{m-1} f[k] t^k \right) \\ &= \sum_{k=0}^{n} g[k] t^k - g[n] t^n - \sum_{k=0}^{m-1} g[n] f[k] t^{n-m+k} \end{aligned}$$

$$= \sum_{k=0}^{n-1} g[k]t^k - \sum_{k=n-m}^{n-1} g[n]f[k-n+m]t^k$$

Thus by induction hypothesis there are some q_0, $r \in R$ with $g - pf = q_0 f + r$ and $\deg(g) < \deg(f)$. But from this equation we find $g = (p + q_0)f + r$ such that we may take $q = q_0 + p$ and r as the required polynomials in the induction step.

Uniqueness: Hereby R is an integral domain. Suppose we had two decompositions $g = pf + r$ and $g = qf + s$, where $r = 0$ or $\deg(r) < \deg(f)$ and $s = 0$ or $\deg(s) < \deg(f)$. Note that these equations can be rewritten, as

$$(q-p)f - (r-s) \; = (qf+s) - (pf+r) \; = \; g - g \; = \; 0$$

This means $(q-p)f = r - s$ But $\deg(r-s) < \deg(f)$ as both r and s are of lower degree. Suppose $q - p \neq 0$ then $\deg((q-p)f) \geq \deg(f)$, since R is an integral domain. But as $\deg((q-p)f) = \deg(r-s) < \deg(f)$ this cannot be. This only leaves the possibility $q - p = 0$ (that is $p = q$) and thereby also $r - s = (q-p)f = 0$ (that is $r = s$). □

15.4 Proofs of Chapter 3

Proof of (3.10):

- First suppose M is an R-module and $P_i \leq_{\mathsf{m}} M$ are R-sub-modules and let $P := \bigcap_i P_i \subseteq M$. In particular we get $0 \in P_i$ for any $i \in I$ and hence $0 \in P$. And if we are given any $x, y \in P$ this means $x, y \in P_i$ for any $i \in I$. And as any $P_i \leq_{\mathsf{m}} M$ is an R-sub-module this implies $x + y \in P_i$ which is $x + y \in P$ again, as i has been arbitrary. Likewise consider any $a \in R$, then $ax_i \in P_i$ again and hence $ax \in P$. Altogether $P \leq_{\mathsf{m}} M$ is an R-sub-module of M.

- Now suppose M is an R-semi-algebra and $P_i \leq_{\mathsf{b}} A$ are R-sub-semi-algebras and let $P := \bigcap_i P_i \subseteq M$ again. In particular $P_i \leq_{\mathsf{m}} M$ and, as we have already seen, this implies $P \leq_{\mathsf{m}} M$. Thus consider any $f, g \in P$ that is $f, g \in P_i$ for any $i \in I$. As any P_i is an R-sub-semi-algebra we get $fg \in P_i$ again and hence $fg \in P$, as i has been arbitrary. Thus P is an R-sub-semi-algebra again.

- Next suppose M is an R-algebra with unit element 1, $P_i \leq_{\mathsf{a}} M$ are R-subalgebras and let $P := \bigcap P_i$ once more. Then we have just seen that $P \leq_{\mathsf{b}} M$ again. But as $P_i \leq_{\mathsf{a}} M$ we have $1 \in P_i$ again. And as this is true for any $i \in I$ this implies $1 \in P$, such that $P \leq_{\mathsf{a}} M$.

- Finally consider the R-semi-algebra A and the R-algebra-ideals $\mathfrak{a}_i \trianglelefteq_{\mathsf{a}} A$ and let $\mathfrak{a} := \bigcap_i \mathfrak{a}_i \subseteq A$. As our first claim we have already shown $\mathfrak{a} \leq_{\mathsf{m}} A$, thus consider any $f \in \mathfrak{a}$ and any $g \in M$. Then we have $f \in \mathfrak{a}_i$ for any $i \in I$ and as this is an R-sub-semi-algebra this implies fg and $gf \in \mathfrak{a}_i$ again. And as i is arbitrary this finally is fg and $gf \in \mathfrak{a}$ such that $\mathfrak{a} \trianglelefteq_{\mathsf{a}} A$, again.

□

Proof of (3.12):

- Let us denote the set $P := \{\sum_i a_i x_i\}$ of which we claim $P = \langle X \rangle_{\mathsf{m}}$. First of all it is clear that $X \subseteq P$, as $x = 1x \in P$ for any $x \in X$. Further it is clear that $P \leq_{\mathsf{m}} M$ is a sub-module of M: choose any $x \in X$, then $0 = 0 \diamond x \in P$, and if $a \in R$, $x = a_1 x_1 + \cdots + a_m x_m$ and $y = b_1 y_1 + \cdots + b_n y_n \in P$ then $ax = (aa_1)x_1 + \cdots + (aa_m)x_m \in P$ and $x + y = a_1 x_1 + \cdots + a_m x_m + b_1 y_1 + \cdots + b_n y_n \in P$. Thus by definition of $\langle X \rangle_{\mathsf{m}}$ we get $\langle X \rangle_{\mathsf{m}} \subseteq P$. Now suppose $Q \leq_{\mathsf{m}} M$ is any sub-module of M containing $X \subseteq Q$. Then for any $a_i \in R$ and any $x_i \in X \subseteq Q$ we get $a_i x_i \in Q$ and hence $\sum_i a_i x_i \in Q$, too. That is $P \subseteq Q$, and as Q has been arbitrary this means $P \subseteq \langle X \rangle_{\mathsf{m}}$, by the definition of $\langle X \rangle_{\mathsf{m}}$.

- Denote the set $P := \{\sum_i a_i \prod_j x_{i,j}\}$ of which we claim $P = \langle X \rangle_{\mathsf{b}}$. Again it is clear, that $X \subseteq P$, as $x = 1x \in P$ for any $x \in X$. Further it is clear that $P \leq_{\mathsf{b}} A$ is a sub-semi-algebra of A: choose any $x \in X$, then $0 = 0 \diamond x \in P$, and if $a \in R$, $f = \sum_i a_i \prod_j x_{i,j}$ and $g = \sum_k b_k \prod_l y_{k,l}$, then $af = \sum_i (aa_i) \prod_j x_{i,j} \in P$, $f + g = \sum_i a_i \prod_j x_{i,j} + \sum_k b_k \prod_l y_{k,l} \in P$ and by general distributivity $fg = \sum_i \sum_j (a_i b_j)(\prod_j x_{i,j} \prod_l y_{k,l}) \in P$. Thus by definition of $\langle X \rangle_{\mathsf{b}}$ we get $\langle X \rangle_{\mathsf{b}} \subseteq P$. Now suppose $Q \leq_{\mathsf{b}} A$ is any sub-semi-algebra of A. Then for any $a_i \in R$ and any $x_{i,j} \in X \subseteq Q$ we get $\prod_j x_{i,j} \in Q$, hence $a_i \prod_j x_{i,j} \in Q$ and finally $\sum_i a_i \prod_j x_{i,j} \in Q$. That is $P \subseteq Q$, and as Q has been arbitrary, this means $P \subseteq \langle X \rangle_{\mathsf{b}}$, by definition of $\langle X \rangle_{\mathsf{b}}$.

- By construction $P := \langle X \cup \{1\} \rangle_{\mathsf{b}}$ is a sub-semi-algeba containing 1, in other words a subalgebra. And as $X \subseteq P$ this implies $\langle X \rangle_{\mathsf{a}} \subseteq P$. And as any subalgebra $Q \leq_{\mathsf{a}} A$ contains 1 we get the

implications $X \subseteq Q \implies X \cup \{1\} \subseteq Q \implies P \subseteq Q$. This also proves $\langle X \rangle_{\mathfrak{a}} \subseteq P$, as Q has been arbitrary.

□

Proof of (3.14):

- We first prove that $\sim$ truly is an equivalence relation, the *reflexivity* $x \sim x$ is clear, as $x - x = 0 \in P$. For the *symmetry* suppose $x \sim y$, that is $y - x \in P$ and hence $x - y = -(y - x) = (-1)(y - x) \in P$. For the *transitivity* we finally consider $x \sim y$ and $y \sim z$. That is $y - x \in P$ and $z - y \in P$ and this yields $z - x = (z - y) + (y - x) \in P$. As in the proof of (1.62) it is clear that $[x] = x + P$, as

$$[x] \;=\; \{\, y \in M \mid y - x \in P \,\} \;=\; x + P$$

- Next we will prove the well-definedness of the addition and scalar-multiplication. Thus consider $x + P = x' + P$ and $y + P = y' + P$, that is $x' - x \in P$ and $y' - y \in P$. As P is an R-sub-module we get $(x' + y') - (x + y) = (x' - x) + (y' - y) \in P$ and this again is $(x + y) + P = (x' + y') + P$. Likewise for any $a \in R$ we get $(ax') - (ax) = a(x' - x) \in P$, which is $ax + P = ax' + P$.

- Now we immediately see, that M/P is an R-module again. The associativity and commutativity of $+$ are inherited trivially from M. And the same is true for the compatibility properties of $\diamond$. The neutral element of M/P is given to be $0 + P$, as for any $x + P \in M/P$ we get $(x + P) + (0 + P) = (x + 0) + P = x + P$. And the inverse of $x + P \in M/P$ is just $(-x) + P$, as $(x + P) + ((-x) + P) = (x + (-x)) + P = 0 + P$.

- Finally suppose A is an R-(semi)algebra, then we want to show that $A/\mathfrak{a}$ is an R-(semi)algebra again. As the R-algebraideal $\mathfrak{a}$ is an R-sub-module $A/\mathfrak{a}$ already is an R-module, by what we have already shown. Next we have to verify the well-definedness of the multiplication. Thus consider $f + \mathfrak{a} = f' + \mathfrak{a}$ and $g + \mathfrak{a} = g' + \mathfrak{a}$, then $(f'g') - (fg) = f'(g' - g) + (f' - f)g \in \mathfrak{a}$, by assumption on $\mathfrak{a}$. Now it is clear that $A/\mathfrak{a}$ inherits the associativity of the multiplication from A. Likewise the compatibility properties of $\cdot$, $+$ and $\diamond$ are inherited trivially. As an example let us regard the identity of

$$\begin{aligned}
\Big(a(f + \mathfrak{a})\Big)(g + \mathfrak{a}) &= (af + \mathfrak{a})(g + \mathfrak{a}) = (af)g + \mathfrak{a} = a(fg) + \mathfrak{a} \\
(f + \mathfrak{a})\Big(a(g + \mathfrak{a})\Big) &= (f + \mathfrak{a})(ag + \mathfrak{a}) = f(ag) + \mathfrak{a} = a(fg) + \mathfrak{a} \\
a\Big((f + \mathfrak{a})(g + \mathfrak{a})\Big) &= a(fg + \mathfrak{a}) = a(fg) + \mathfrak{a}
\end{aligned}$$

□

Proof of (3.16):

(i) We will first prove the equivalence $x + L \in P/L \iff x \in P$. The one implication is trivial: if $x \in P$, then $x + L \in P/L$ by definition. Conversely suppose there is some $p \in P$ such that $x + L = p + L \in P/L$. By definition of M/L this means $x - p \in L$, that is $x - p = \ell$ for some $\ell \in L \subseteq P$. And therefore $x = p + \ell \in P$, as $p, \ell \in P$ and $P \leq_{\mathfrak{m}} M$.

Now we are ready to prove $P/L \leq_{\mathsf{m}} M/L$, clearly $0 = 0 + L \in P/L$, as we have $0 \in P$. Now consider $x + L$ and $y + L \in P/L$, by what we have just seen this means x and $y \in P$. As $P \leq_{\mathsf{m}} M$ this implies $x + y \in P$ and hence $(x + L) + (y + L) = (x + y) + L \in P/L$ again. Finally consider any $a \in R$, as $x \in P$ and $P \leq_{\mathsf{m}} M$ this implies $ax \in P$ and hence also $a(x + L) = (ax) + L \in P/L$. Altogether P/L is a sub-module of M/L.

(ii) In (i) we have seen that $P \mapsto P/L$ is a well-defined map, so next we will point out that $U \mapsto (U) := \{ x \in M \mid x + L \in U \}$ is well-defined, too. That is we have to verify $(U) \leq_{\mathsf{m}} M$ and $L \subseteq (U)$. The containment $L \subseteq (U)$ is clear, if $\ell \in L$ then $\ell + L = 0 + L = 0 \in U$ and hence $\ell \in (U)$. In particular $0 \in (U)$. Next suppose we age given x, $y \in (U)$, that is $x + L$, $y + L \in U$. Then $(x + y) + L = (x + L) + (y + L) \in U$ as $U \leq_{\mathsf{m}} M/L$ and hence $x + y \in (U)$ again. Likewise for any $a \in R$ we get $(ax) + L = a(x + L) \in U$ and hence $ax \in (U)$, as $x + L \in U$ and $U \leq_{\mathsf{m}} M/L$. Thus both maps given are well-defined. It remains to verify that they are mutually inverse: the one direction is easy, consider any $U \leq_{\mathsf{m}} M/L$, then $U \mapsto (U) \mapsto (U)/L = \{ x + L \mid x + L \in U \} = U$. Conversely consider any $L \subseteq P \leq_{\mathsf{m}} M$, then $P \mapsto P/L \mapsto (P/L)$, yet using (i) we obtain $(P/L) = P$ from the following computation

$$\left(P \Big/ L\right) \;=\; \left\{ x \in M \mid x + L \in P \Big/ L \right\} \;=\; \{ x \in M \mid x \in P \} \;=\; P$$

(iii) To prove this claim we just have to iterate the equivalence in (i): $x + L \in (\bigcap_i P_i)/L$ is equivalent to $x \in \bigcap_i P_i$, which again is equivalent to $\forall\, i \in I : x \in P_i$. Now we use (i) once more to reformulate this into the equivalent statement $\forall\, i \in I : x + L \in P_i/L$, which obviously translates into $x + L \in \bigcap_i (P_i/L)$ again.

(iv) We want to verify $\sum_i (P_i/L) = (\sum_i P_i)/L$, to do this recall the explicit description of an arbitrary sum of sub-modules for the $P_i/L \leq_{\mathsf{m}} M/L$

$$\sum_{i \in I} \left(P_i \Big/ L\right) \;=\; \left\{ \sum_{i \in \Omega} (x_i + L) \;\middle|\; \Omega \subseteq I \text{ finite}, x_i + L \in P_i \Big/ L \right\}$$

Next recall the equivalence in (i), this allows us to simply substitute $x_i + L \in P_i/L$ by $x_i \in P_i$. Further - by definition of $+$ in M/L - we can rewrite the sum $\sum_i (x_i + L) = (\sum_i x_i) + L$. Together this yields

$$\sum_{i \in I} \left(P_i \Big/ L\right) \;=\; \left\{ \left(\sum_{i \in \Omega} x_i \right) + L \;\middle|\; \Omega \subseteq I \text{ finite}, x_i \in P_i \right\}$$

That is the term on the right hand side is (apart from the $+L$ in $(\sum_i x_i) + L$) nothing but the sum $\sum_i P_i$ again (by the explicit description of arbitrary sums of the sub-modules P_i. That is we have already arrived at our claim $\sum_i (P_i/L) = (\sum_i P_i)/L$.

(v) Let us denote $P_i' := P_i + L$, then it is clear that $L \subseteq P_i'$ for any $i \in I$. But on the other hand $\sum_i P_i' = \sum_i (P_i + L) = (\sum_i P_i) + L$ as the finitely many occurances of elements $\ell_i \in L$ can be composed to a single occurance of $\ell := \sum_i \ell_i \in L$. But by assumption L is already contained in $\sum_i P_i$ and hence $(\sum_i P_i) + L = \sum_i P_i$. That is we have obtained $\sum_i P_i' = \sum_i P_i$. Now statement (iv), that has just been proved, yields $(\sum_i P_i)/L = (\sum_i P_i')/L = \sum_i (P_i'/L)$, as claimed.

(vi) To prove this identity we directly refer to the definition of the R-sub-module generated by $X/L \subseteq M/L$. And this is given to be

$$\langle X/L \rangle_{\mathsf{m}} \;=\; \bigcap \Big\{ U \leq_{\mathsf{m}} M/L \;\Big|\; X/L \subseteq U \Big\}$$

By (ii) the sub-modules U of M/L correspond bijectively to the sub-modules P of M containing L. I.e. we may insert P/L for U, yielding

$$\langle X/L \rangle_{\mathsf{m}} \;=\; \bigcap \Big\{ P/L \;\Big|\; L \subseteq P \leq_{\mathsf{m}} M,\, X/L \subseteq P/L \Big\}$$

Clearly $X/L \subseteq P/L$ translates into $\forall\, x \in X : x + L \in P/L$, and due to the equivalence in (i) this is $\forall\, x \in X : x \in P$, i.e. $X \subseteq P$, therefore

$$\langle X/L \rangle_{\mathsf{m}} \;=\; \bigcap \Big\{ P/L \;\Big|\; L \subseteq P \leq_{\mathsf{m}} M,\, X \subseteq P \Big\}$$

Of course $L \subseteq P$ and $X \subseteq P$ can be written more compactly as $X \cap L \subseteq P$. And due to (iii) the intersection commutes with taking to quotients, such that we may reformulate

$$\langle X/L \rangle_{\mathsf{m}} \;=\; \bigcap \{ P \mid P \leq_{\mathsf{m}} M,\, X \cap L \subseteq P \} \big/ L$$

That is we have arrived at $\langle X/L \rangle_{\mathsf{m}} = \langle X \cup L \rangle_{\mathsf{m}}/L$. But by the explicit representation of the generated sub-modules (3.12) it is clear, that $\langle X \cap L \rangle_{\mathsf{m}} = \langle X \rangle_{\mathsf{m}} + \langle L \rangle_{\mathsf{m}}$. And as L already is a sub-module of M we have $\langle L \rangle_{\mathsf{m}} = L$. Altogether $\langle X/L \rangle_{\mathsf{m}} = (\langle X \rangle_{\mathsf{m}} + L)/L$.

□

Proof of (3.17):

- Let us first prove the identity part in the modular rule, starting with $(Q \cap U) + P \subseteq Q \cap (P + U)$. Thus we consider any $x \in Q \cap U$ and $p \in P$ and have to verify $x + p \in Q \cap (P + U)$. As $x \in Q$ and $p \in P \subseteq Q$ we have $x + p \in Q$. And as also $x \in U$ we have $x + p \in U + P$ hence the claim. Conversely for $(Q \cap U) + P \supseteq Q \cap (P + U)$ we are given any $p \in P$ and $u \in U$ such that $q := p + u \in Q$ and we have to verify $p + u \in (Q \cap U) + P$. But as $u = q - p$ and $p, q \in Q$ we find $u \in Q$ and hence $u \in Q \cap U$. And this already is $p + u = u + p \in (Q \cap U) + P$.

- So it remains to verify the implication in the modular rule. As $P \subseteq Q$ by assumption it remains to prove $Q \subseteq P$. Thus consider any $q \in Q$, then in particular $q \in Q + U = P + U$. That is there are $p \in P$ and $u \in U$ such that $q = p + u$. And as $p \in P \subseteq Q$ this yields $u = q - p \in Q$, such that $u \in Q \cap U = P \cap U$. In particular $u \in P$ and hence $q = p + u \in P$, as claimed.

□

Proof of (3.22):

(i) We will first prove that $\mathrm{ann}(X)$ is a left-ideal of R. As this is just the intersection of the annihilators $\mathrm{ann}(x)$ (where $x \in X$) it suffices to verify $\mathrm{ann}(x) \leq_{\mathsf{m}} R$ for any $x \in M$, due to (1.52). Now $0 \in \mathrm{ann}(x)$ is clear, as $0 \diamond x = 0$ for any $x \in M$. Now consider any two $a, b \in \mathrm{ann}(x)$, that is $ax = 0$ and $bx = 0$. Then $(a + b)x = (ax) + (bx) = 0 + 0 = 0$ and hence $a + b \in \mathrm{ann}(x)$ again.

Finally consider any $r \in R$, then $(ra)x = r(ax) = r \diamond 0 = 0$ and hence $ra \in \operatorname{ann}(x)$, as well. Altogether we have $\operatorname{ann}(x) \leq_{\mathsf{m}} R$ and hence $\operatorname{ann}(X) \leq_{\mathsf{m}} R$ is a left-ideal, as it is an intersection of such.

(i) Next we want to prove that $\operatorname{ann}(P) \trianglelefteq_{\mathsf{i}} R$ even is an ideal. As we already know $\operatorname{ann}(P) \leq_{\mathsf{m}} R$ it only remains to prove that $ar \in \operatorname{ann}(P)$ for any $a \in \operatorname{ann}(P)$ and any $r \in R$. As $a \in \operatorname{ann}(P)$ we have $ap = 0$ for any $p \in P$. Now consider any $x \in P$, then $rx \in P$, too as P is a sub-module of M. Thus $(ar)x = a(rx) = 0$, as we can take $p = rx$. And as $x \in P$ was arbitrary this means $ar \in \operatorname{ann}(P)$ again.

(ii) Let us denote $\Phi : R/\operatorname{ann}(x) \to Rx : \overline{b} := b + \operatorname{ann}(x) \mapsto bx$, we will first prove the well-definedness and injectivity of this map: $ax = \Phi(\overline{a}) = \Phi(\overline{b}) = bx$ is equivalent to $(a-b)x = 0$, that is $a - b \in \operatorname{ann}(x)$ or in other words $\overline{a} = a + \operatorname{ann}(x) = b + \operatorname{ann}(x) = \overline{b}$. The surjectivity of Φ is clear, as any $b \in R$ is allowed. And Φ also is a homomorphism of R-modules, as by definition of the algebraic operations of $R/\operatorname{ann}(x)$ we have $\Phi(\overline{a} + \overline{b}) = \Phi(\overline{a+b}) = (a+b)x = (ax) + (bx) = \Phi(\overline{a}) + \Phi(\overline{b})$ and $\Phi(a\overline{b}) = \Phi(\overline{ab}) = (ab)x = a(bx) = a\Phi(\overline{b})$. Nota that this proof was completely elementary. It can also be proved regarding the epimorphism $\varphi : R \to Rx : b \mapsto bx$ and noting that its kernel is $\operatorname{kn}(\varphi) = \operatorname{ann}(x)$. If we now invoke the first isomorphism theorem of R-modules, we get Φ.

(ii) If $\mathfrak{a} = \operatorname{ann}(x)$ for some $x \in M$ with $x \neq 0$, then we have just seen, that $\iota : R/\mathfrak{a} \xrightarrow{\sim} Rx \leq_{\mathsf{m}} M$ defined by $\iota(b + \mathfrak{a}) := bx$ is a monomorphism of the desired form. Conversely: As $\mathfrak{a}$ is proper we have $1 \notin \mathfrak{a}$ and thereby $1 + \mathfrak{a} \neq 0 \in R/\mathfrak{a}$. And as ι is injective, this means $x := \iota(1 + \mathfrak{a}) \neq 0 \in M$. Also for any $b \in R$ we have $\iota(b + \mathfrak{a}) = b\iota(1 + \mathfrak{a}) = bx$ such that $bx = 0$ is equivalent to $b + \mathfrak{a} = 0$ which again is $b \in \mathfrak{a}$. That is we have $\mathfrak{a} = \operatorname{ann}(x)$ for some $x \neq 0$.

(iii) First consider $x = 0$, then $ax = a0 = 0$ is clear for any $a \in S$ and hence $\operatorname{ann}(x) = S$. Secondly consider $x \neq 0$ and $a \in \operatorname{ann}(x)$, that is $ax = 0$. Suppose we had $a \neq 0$, too, then (as S is a skew-field) there was some $a^{-1} \in S$ such that $a^{-1}a = 1$. Then we would be able to compute $x = 1x = (a^{-1}a)x = a^{-1}(ax) = a^{-1}0 = 0$, a contradiction to $x \neq 0$, such that $a = 0$ and therefore $\operatorname{ann}(x) = 0$. In other words $S \to Sx : a \mapsto ax$ is injective for any $x \neq 0$. But the surjectivity is trivial, so this map is an isomorhism of S-vector spaces.

(iv) Let us abbreviate $P := \langle X \rangle_{\mathsf{m}}$, then by definition it is clear that $X \subseteq P$ and hence $\operatorname{ann}(P) \subseteq \operatorname{ann}(X)$. For the converse inclusion consider any $a \in \operatorname{ann}(X)$, then we have to show $a \in \operatorname{ann}(P)$. That is $ap = 0$ for any $p \in P$. By (3.12) any $p \in P$ is given to be $p = \sum_i a_i x_i$ for some $a_i \in R$ and $x_i \in X$. Therefore $ap = \sum_i (aa_i)x_i = \sum_i a_i(ax_i) = \sum_i a_i 0 = 0$ as R is commutative. Altogether that is $\operatorname{ann}(X) = \operatorname{ann}(P)$. If X generates M, that is $P = M$, then we hence find $\operatorname{ann}(M) = \operatorname{ann}(X) = \bigcap_i \operatorname{ann}(x_i)$ as well.

(iv) Now suppose $M = \langle X \rangle_{\mathsf{m}}$ where $X = \{ x_i \mid i \in I \}$ and consider the map $\varphi : R \to M^I$ defined by $\varphi(a) := (ax_i)$ (where $i \in I$). If now $a \in \operatorname{ann}(M) = \operatorname{ann}(X)$ then $ax_i = 0$ for any $i \in I$ and hence $\varphi(a) = 0$ is clear. Therefore we have $\operatorname{ann}(M) \subseteq \operatorname{kn}(\varphi)$. Conversely $\varphi(a) = 0$ means $ax_i = 0$ for any $i \in I$, that is $a \in \operatorname{ann}(X) = \operatorname{ann}(M)$ and hence even $\operatorname{kn}(\varphi) = \operatorname{ann}(M)$. Thereby $R/\operatorname{ann}(M) \hookrightarrow M^I$ is well-defined and injective according to the first isomorphism theorem (3.78.(ii))

(v) We first have to check the well-definedness of the scalar multiplication. To do this consider any $b+\mathfrak{a} = c+\mathfrak{a}$, that is $a := c-b \in \mathfrak{a} \subseteq \operatorname{ann}_R(M)$. If now $x \in M$ is an arbitrary element, then $cx = (a+b)x = ax+bx = 0+bx = bx$, as a annihilates any $x \in M$. Hence $(b+\mathfrak{a}, x) \mapsto bx$ does not depend on the specific $b \in R$ chosen. As we have only changed the scalar-multiplication on M, it remains to prove, that it still satisfies the properties (M) in the definition of modules. Thus consider any $a, b \in R$ and any $x, y \in M$. Then we can compute

$$\begin{aligned}
(a+\mathfrak{a})(x+y) &= a(x+y) \;=\; ax+ay \\
&= (a+\mathfrak{a})x + (a+\mathfrak{a})y \\
((a+\mathfrak{a})+(b+\mathfrak{a}))x &= ((a+b)+\mathfrak{a})x \;=\; (a+b)x \\
&= ax+bx \;=\; (a+\mathfrak{a})x + (b+\mathfrak{a})x \\
((a+\mathfrak{a})(b+\mathfrak{a}))x &= ((ab)+\mathfrak{a})x \;=\; (ab)x \;=\; a(bx) \\
&= (a+\mathfrak{a})(bx) \;=\; (a+\mathfrak{a})((b+\mathfrak{a})x) \\
(1+\mathfrak{a})x &= 1x \;=\; x
\end{aligned}$$

□

Proof of (3.23):

(i) By definition an integral domain is non-zero $R \neq 0$, such that $1 \neq 0$. As also $1 \diamond 0 = 0$ we already have $0 \in \operatorname{tor}(M)$. Now consider any two $x, y \in \operatorname{tor}(M)$, that is there are some $0 \neq a, b \in R$ such that $ax = 0$ and $by = 0$. As R is an integral domain we also get $ab \neq 0$. Now compute $(ab)(x+y) = (ab)x + (ab)y = (ba)x + (ab)y = b(ax) + a(by) = b \diamond 0 + a \diamond 0 = 0+0 = 0$. That is $(ab)(x+y) = 0$ and hence $x+y \in M$, as $ab \neq 0$. Finally consider any $r \in M$, then we need to show $rx \in \operatorname{tor}(M)$. But this is clear from $a(rx) = (ar)x = (ra)x = r(ax) = r \diamond 0 = 0$.

(i) Let us abbreviate $T := \operatorname{tor}(M)$, now consider any $x+T \in \operatorname{tor}(M/T)$. That is there is some $0 \neq a \in R$ such that $(ax)+T = a(x+T) = 0+T$. This is just $ax \in T$, that is there is some $0 \neq b \in R$, such that $(ba)x = b(ax) = 0$. As R is an integral domain, we get $ba \neq 0$ and this means $x \in T$, such that $x+T = 0+T$. Thus we have just proved $\operatorname{tor}(M/T) \subseteq \{\, 0+T \,\} = \{0\}$ and the converse containment is clear.

(ii) Let $\{\, m_i \mid i \in I \,\}$ be a basis of M and consider any $x \in P$. Suppose there was some $0 \neq a \in R$ such that $ax = 0$. Then we write x as a linear combination of the m_i and find

$$x \;=\; \sum_{i \in I} x_i m_i \quad\Longrightarrow\quad 0 \;=\; ax \;=\; \sum_{i \in I} a x_i m_i$$

As the m_i are linearly independent, by assumption, this means $ax_i = 0$ for all $i \in I$. But as $a \neq 0$ and R is an integral domain this implies $x_i = 0$ for all $i \in I$ such that $x = 0$. That is we have proved that $ax = 0$ implies $x = 0$ for any $x \in P$. But this is $\operatorname{tor}(P) \subseteq 0$ and the converse inclusion is trivial.

(iii) (a) $\Longrightarrow$ (b): As $R \neq 0$ we have $1 \neq 0$ and as $1 \diamond 0 = 0$ this implies $0 \in \operatorname{tor}(M)$. Conversely consider any $x \in \operatorname{tor}(M)$, that is there is some $a \in R$ such that $a \neq 0$ but $ax = 0$. Suppose we had $x \neq 0$, then $a \in \operatorname{zd}_R(M) \subseteq \{0\}$ (by definition of $\operatorname{zd}_R(M)$, as $x \neq 0$ and $ax = 0$) which is

$a = 0$ again. But as $a \neq 0$ this is a contradiction. Thus we necessarily have $x = 0$ and as x has been arbitrary this means $\text{TOR}(M) \subseteq \{0\}$, as well.

(iii) (b) $\implies$ (c): Consider any $x \in M$ with $x \neq 0$, then $\text{ann}(x) = \{\, a \in R \mid ax = 0 \,\}$. If there was some $a \neq 0$ with $a \in \text{ann}(x)$, then $x \in \text{TOR}(M) = \{0\}$, which is untrue, as $x \neq 0$. Thus we have $\text{ann}(x) = 0$. As $M \neq 0$ we find (c).

(iii) (c) $\implies$ (d): Consider any $a \in R$ and any $x \in M$ such that $ax = 0$. If $x = 0$ we we are done, else $a \in \text{ann}(x) \in \text{Anns}(M) = \{0\}$. That is $a \in \text{ann}(x) = \{\, a \in R \mid ax = 0 \,\} = \{0\}$ and hence $a = 0$.

(iii) (d) $\implies$ (a): Consider any $a \in \text{ZD}_R(M)$, that is there is some $x \in M$ such that $x \neq 0$ and $ax = 0$. Thus by assumption (d) we find $a = 0$, and as a has been arbitrary, this means $\text{ZD}_R(M) \subseteq \{0\}$, as claimed.

(iv) (b) $\implies$ (a) is simple: If $\mu : M \hookrightarrow R^n$, then M is isomorphic to $N := \mu(M) \leq_{\mathsf{m}} R^n$. But as R^n is free [it has the Euclidean basis] and R is an integral domain (ii) tells us that N is torsion-free. Due to the isomorphism $\mu : M \xrightarrow{\sim} N$ this means M is torsion-free. Conversely for (a) $\implies$ (b) pick up a generating set $\{\, m_1, \ldots, m_r \,\}$ of M. If $M = 0$ we are done with $M \hookrightarrow R : 0 \mapsto 0$, so let us assume $M \neq 0$ and hence $m_i \neq 0$ for any $i \in 1 \ldots r$. Now let

$$\mathcal{L} \;:=\; \{\, I \subseteq 1 \ldots r \mid \{\, m_i \mid i \in I \,\} \text{ is linear independent} \,\}$$

By assumption $am_i \implies a = 0$ such that any $\{\, i \,\} \in \mathcal{L}$, in particular $\mathcal{L}$ is non-empty. But also $\mathcal{L}$ is finite [it contains 2^r elements at most]. So we may choose some $I \in \mathcal{L}$ that is maximal, that is $\{\, m_i \mid i \in I \,\}$ is linear independent and for any $j \notin I$ the set $\{\, m_i \mid i \in I \,\} \cup \{\, m_j \,\}$ is linearly dependent. Now let

$$\Phi \;:\; R^I \hookrightarrow M \;:\; (a_i) \mapsto \sum_{i \in I} a_i m_i$$

As $\{\, m_i \mid i \in I \,\}$ is linearly independent this homomorphism is injective. If we denote its image by $F := \text{im}(\Phi) \leq_{\mathsf{m}} M$ we even have an isomorphism $\Phi : R^I \xrightarrow{\sim} F \leq_{\mathsf{m}} M$. But by construction of I for any $j \in J$ the set $\{\, m_i \mid i \in I \,\} \cup \{\, m_j \,\}$ is linearly dependent, that is there are some $a_j \in R$ and some $a_{i,j} \in R$ (not all zero) such that

$$\sum_{i \in I} a_{i,j} m_i + a_j m_j \;=\; 0$$

If thereby $a_j = 0$, then there was some $a_{i,j} \neq 0$, which is absurd, since $\{\, m_i \mid i \in I \,\}$ is linear independent. But from this we get

$$a_j m_j \;=\; -\sum_{i \in I} a_{i,j} m_i \;\in\; \text{Lh}\{\, m_i \mid i \in I \,\} \;=\; F$$

If we take $a := \prod_{j \notin I} a_j$ then $a \neq 0$, as any $a_j \neq 0$ and R is an integral domain. But by construction also $am_j \in F$ for any $j \notin I$ and $am_i \in F$ for any $i \in I$ is clear. Thus we have $aM \subseteq F$. But as M is torsion free, the homomorphism

$$\alpha \;:\; M \hookrightarrow F \;:\; x \mapsto ax$$

has kernel $\mathrm{kn}(\alpha) = 0$, as $ax = 0$ implies $x = 0$. That means α is injective. And thereby we have found the embedding $\mu := \Phi^{-1}\alpha$ of M into R^I that is of the desired form

$$\Phi^{-1}\alpha \;:\; M \hookrightarrow F \;\xrightarrow{\sim}\; R^I$$

(v) If $x \in \mathrm{tor}(M)$ then there is some $0 \neq a \in R$ with $ax = 0$. But since Φ is a homomorphism this means $a\Phi(x) = \Phi(ax) = \Phi(0) = 0$ such that $\Phi(x) \in \mathrm{tor}(N)$. As x was arbitrary this means

$$\Phi(\mathrm{tor}(M)) \quad \subseteq \quad \mathrm{tor}(N)$$

With the same reasoning we find $\Phi^{-1}(\mathrm{tor}(N)) \subseteq \mathrm{tor}(M)$ and hence $\mathrm{tor}(N) \subseteq \Phi(\mathrm{tor}(M))$. Thus we have proved $\Phi(\mathrm{tor}(M)) = \mathrm{tor}(N)$. In particular $\Phi : \mathrm{tor}(M) \xrightarrow{\sim} \mathrm{tor}(N)$ is an isomorphism, as it is well-defined, surjective and inherits both the injectivity and the R-linearity from Φ. It remains to prove that

$$M\Big/_{\mathrm{tor}(M)} \;\xrightarrow{\sim}\; N\Big/_{\mathrm{tor}(N)} \;:\; x + \mathrm{tor}(M) \;\mapsto\; \Phi(x) + \mathrm{tor}(N)$$

is an isomorphism, as well. To do this regard $x + \mathrm{tor}(M) = y + \mathrm{tor}(M)$, that is $y - x \in \mathrm{tor}(M)$ and as Φ is injective this is equivalent to $\Phi(y - x) \in \Phi(\mathrm{tor}(M)) = \mathrm{tor}(N)$. As $\Phi(y - x) = \Phi(y) - \Phi(x)$ this is again equivalent to $\Phi(x) + \mathrm{tor}(N) = \Phi(y) + \mathrm{tor}(N)$. Thus we have established the well-definedness and injectivity at the same time. But as Φ is surjective so is $x + \mathrm{tor}(M) \mapsto \Phi(x) + \mathrm{tor}(N)$ and therefore we have another isomorphism.

(vi) Let us denote the set of all proper, pure sub-modules P of M by $\mathcal{P}$, that is $\mathcal{P} := \{ P \leq_{\mathfrak{m}} M \mid P \neq M, P \text{ is pure}$ As M is torsion free $0 \leq_{\mathfrak{m}} M$ is a pure sub-module of M ($ax = 0$ implies $a = 0$ or $x = 0$). Also $0 \neq M$ such that $\mathcal{P}$ is non-empty. Now consider a chain $(P_i) \subseteq \mathcal{P}$ in $\mathcal{P}$, then we let

$$Q \;:=\; \bigcup_{i \in I} P_i$$

As (P_i) is a chain we know that Q is a sub-module of M again. Now suppose we had $Q = M$. As M is finitely generated we find some $m_k \in M$ such that $M = \mathrm{Lh}(x_1, \ldots, x_n)$. And as (for any $k \in 1 \ldots n$) $x_k \in M = Q$ there is some $i(k) \in I$ such that $x_k \in P_{i(k)}$. Taking to the maximum of the $P_{i(k)}$ we find $x_k \in P_i$ for some $i \in I$. But this would imply $P_i = M$ in contradiction to our assumption. Hence $Q \neq M$.

In fact Q even is pure again: suppose we have $ax \in Q$, that is $ax \in P_i$ for some $i \in I$. And as this P_i has been pure we find $x \in P_i$ which yields $x \in Q$ again. Hence every chain (P_i) in $\mathcal{P}$ has an upper bound $Q \in \mathcal{P}$ and therefore $\mathcal{P}$ has a maximal element, due to the lemma of Zorn.

□

Proof of (3.24):

(i) Choose any $x \in M$, yet $x \neq 0$. Then $Rx = \{ bx \mid b \in R \}$ is a non-zero sub-module of M. But as $0 \neq Rx \leq_{\mathfrak{m}} M$ and M is simple we get $Rx = M$. Hence we get

$$\mathfrak{m} \;:=\; \mathrm{ann}_R(M) \;=\; \{ a \in R \mid \forall\, y \in Rx : ay = 0 \}$$

$$= \{ a \in R \mid \forall\, b \in R : abx = 0 \}$$
$$= \{ a \in R \mid ax = 0 \} = \operatorname{ann}(x)$$

Here $\{ a \in R \mid \forall\, b \in R : abx = 0 \} \subseteq \operatorname{ann}(x)$ is clear - just take $b = 1$. And the converse inclusion follows easily: if $ax = 0$, that $abx = b(ax) = b0 = 0$ as well. So by (ii) we obtain an isomorphy of R-modules

$$R\big/_{\mathfrak{m}} \xrightarrow{\sim} M \;:\; a + \mathfrak{m} \mapsto ax$$

Now, as M is simple, so is $R/\mathfrak{m}$. That is $0 = \mathfrak{m}/\mathfrak{m}$ is a maximal ideal of $R/\mathfrak{m}$. That is $R/\mathfrak{m}$ is a field and this again means that $\mathfrak{m}$ is a maximal ideal of R.

(ii) Let us first prove (b) $\Longrightarrow$ (a): That is we consider $ab \in \operatorname{ann}(x)$ and have to prove $a \in \operatorname{ann}(x)$ or $b \in \operatorname{ann}(x)$. Note that $ab \in \operatorname{ann}(x)$ is just $abx = 0$ and distinguish two cases: If $\operatorname{ann}(ax) = R$, then $1 \in \operatorname{ann}(ax)$ such that $ax = 0$, which is $a \in \operatorname{ann}(x)$. And if $\operatorname{ann}(ax) = \operatorname{ann}(x)$, then $bax = abx = 0$ can we put as $b \in \operatorname{ann}(ax) = \operatorname{ann}(x)$, such that $b \in \operatorname{ann}(x)$. Altogether $\operatorname{ann}(x)$ is prime.

It remains to prove (a) $\Longrightarrow$ (b): Clearly, if $a \in \operatorname{ann}(x)$, then $ax = 0$ such that $\operatorname{ann}(ax) = \operatorname{ann}(0) = R$. So let us assume $a \notin \operatorname{ann}(x)$ and consider $b \in \operatorname{ann}(ax)$. That is $bax = 0$ and hence $ba \in \operatorname{ann}(x)$. As $\operatorname{ann}(x)$ is prime and $a \notin \operatorname{ann}(x)$ this implies $b \in \operatorname{ann}(x)$. Thus we have proved $\operatorname{ann}(ax) \subseteq \operatorname{ann}(x)$. But the converse inclusion $\operatorname{ann}(x) \subseteq \operatorname{ann}(ax)$ is generally true: if $b \in \operatorname{ann}(x)$ then $bx = 0$, in particular $0 = a\,0 = a\,bx = b\,ax$ such that $b \in \operatorname{ann}(ax)$, as well. Thus we have $\operatorname{ann}(x) = \operatorname{ann}(ax)$ in case $a \notin \operatorname{ann}(x)$.

(iii) By definition $\operatorname{Anns}(Ry)$ is the set of all $\operatorname{ann}(z)$ for some $z \in Ry$ with $z \neq 0$. As $a \notin \mathfrak{p} = \operatorname{ann}(x)$ we have $y = ax \neq 0$ and as $y \in Ry$ this is $\operatorname{ann}(y) \in \operatorname{Anns}(Ry)$ such that $\operatorname{Anns}(Ry) \neq \emptyset$. It remains to verify, that $\operatorname{ann}(by) = \mathfrak{p}$ for any $b \in R$ such that $by \neq 0$. As $y = ax$ this is $\operatorname{ann}(bax) = \mathfrak{p} = \operatorname{ann}(x)$ whenever $bax \neq 0$. As $bax \neq 0$ we also have $ax \neq 0$. Then $b \notin \operatorname{ann}(ax)$ implies $\operatorname{ann}(ax) \neq 0$ and as $\operatorname{ann}(x)$ is prime, (ii) only leaves the option $\operatorname{ann}(ax) = \operatorname{ann}(x)$. But also $\operatorname{ann}(bax) =\neq R$ (as $1 \notin \operatorname{ann}(abx)$) and $\operatorname{ann}(ax) = \operatorname{ann}(x)$ is prime, such that (ii) implies $\operatorname{ann}(by) = \operatorname{ann}(bax) = \operatorname{ann}(x) = \mathfrak{p}$ again.

(iii) Let $\mathfrak{p} = \operatorname{ann}(x)$ be a maximal annihilator ideal of M with $\mathfrak{p} \neq R$. Further consider any $a, b \in R$ with $ab \in \mathfrak{p}$ but $b \notin \mathfrak{p}$, then it remains to verify $a \in \mathfrak{p}$. As $b \notin \mathfrak{p}$ we have $bx \neq 0$. Now consider $\mathfrak{a} := \operatorname{ann}(bx)$, as $bx \neq 0$ we have $1 \notin \mathfrak{a}$ and hence $\mathfrak{a} \neq R$. Also if $p \in \mathfrak{p}$, then $p(bx) = b(px) = b0 = 0$ and hence $p \in \mathfrak{a}$, which means $\mathfrak{p} \subseteq \mathfrak{a}$. But by maximality of $\mathfrak{p}$ this is $\mathfrak{p} = \mathfrak{a}$. Now as $ab \in \mathfrak{p}$ we have $a(bx) = (ab)x = 0$ such that $a \in \mathfrak{a} = \mathfrak{p}$, as has been claimed.

□

Proof of (3.25):
Let us first prove that $Q : P$ is a sub-module of R: As $0\,P = 0 \subseteq Q$ we always have $0 \in Q : P$. Now if a, $b \in Q : P$ then for any $p \in P$ we get $ap \in aP \subseteq Q$ and $bp \in bP \subseteq Q$ such that $(a+b)p = ap + bp \in Q$, as Q is a sub-module of M, and hence $a + b \in Q : P$. And if $a \in Q : P$ then $aP \subseteq Q$, such that for any $b \in R$ we find $(ba)P = b(aP) \subseteq bQ \subseteq Q$ and hence $ba \in Q : P$ again. Together this is $Q : P \leq_{\mathsf{m}} R$. And $0 : M = \{ a \in R \mid aM \subseteq 0 \} = \operatorname{ann}(M)$ is obvious.
If now R is commutative, then $Q : P \leq_{\mathsf{m}} R$ implies $Q : P \trianglelefteq_{\mathsf{i}} R$ and we look at $\operatorname{ann}(x) = \{ a \in R \mid ax = 0 \}$ and $0 : Rx = \{ a \in R \mid aRx \subseteq 0 \}$. As $x \in Rx$ we get $a \in 0 : Rx \Longrightarrow a \in \operatorname{ann}(x)$. Conversely as R is

commutative $ax = 0$ implies $a(bx) = b(ax) = b\,0 = 0$ for any $b \in R$ such that $a \in 0 : Rx$, as well. □

Proof of (3.29):

- We will first verify that the exterior direct product $P := \prod_i M_i$ is an R-module again (under the operations given). The well-definedness of the operations is clear. Thus consider $x = (x_i)$, $y = (y_i)$ and $z = (z_i) \in P$. Then $x + (y + z) = (x_i + (y_i + z_i)) = ((x_i + y_i) + z_i) = (x + y) + z$ which is the associativity. Likewise $x + y = (x_i + y_i) = (y_i + x_i) = y + x$, which is the commutativity. Letting $0 := (0_i)$, where $0_i \in M_i$ is the zero-element, we find $x + 0 = (x_i + 0_i) = (x_i) = x$, such that $0 \in P$ is the zero-element. And the negative of x is $\overline{x} = (-x_i) \in P$, as $x + \overline{x} = (x_i + (-x_i)) = (0_i) = 0$. Now consider any a, $b \in R$ then $a(x + y) = (a(x_i + y_i)) = ((ax_i) + (ay_i)) = (ax_i) + (ay_i) = (ax) + (ay)$. Likewise $(a + b)x = ((a + b)x_i) = ((ax_i) + (bx_i)) = (ax_i) + (bx_i) = (ax) + (bx)$ and $(ab)x = ((ab)x_i) = (a(bx_i)) = a(bx_i) = a(bx)$. Finally $1x = (1x_i) = (x_i) = x$, such that altogether P is an R-module again.

- Let us now verify that the direct sum $S := \bigoplus_i M_i$ is an R-sub-module of the direct product P. Thus we only have to prove that S is closed under the operations of P. However for any $a \in R$ and any x, $y \in S$ it is clear that $\mathrm{Supp}(ax) \subseteq \mathrm{Supp}(x)$ and $\mathrm{Supp}(x + y) \subseteq \mathrm{Supp}(x) \cup \mathrm{Supp}(y)$. Hence $\#\mathrm{Supp}(ax) \leq \#\mathrm{Supp}(x) < \infty$ and $\#\mathrm{Supp}(x + y) \leq \#\mathrm{Supp}(x) + \#\mathrm{Supp}(y) < \infty$. Thereby ax and $x + y \in S$ again.

- If now A_i is an R-semi-algebra (where $i \in I$ again) then we have verified that $P = \prod_i A_i$ is an R-module already. So let us again consider $x = (x_i)$, $y = (y_i)$ and $z = (z_i) \in A$ again. Then $x(yz) = (x_i)(y_i z_i) = (x_i(y_i z_i)) = ((x_i y_i)z_i) = (x_i y_i)(z_i) = (xy)z$ and likewise $x(y + z) = (x_i)(y_i + z_i) = (x_i(y_i + z_i)) = (x_i y_i + x_i z_i) = (x_i y_i) + (x_i z_i) = xy + xz$ and $(x + y)z = (x_i + y_i)(z_i) = ((x_i + y_i)z_i) = (x_i z_i + y_i z_i) = (x_i z_i) + (y_i z_i) = xz + yz$. Also for any $a \in R$ we get $a(xy) = a(x_i y_i) = (a(x_i y_i)) = ((ax_i)y_i) = (ax_i)(y_i) = (ax)y$ and likewise $a(xy) = a(x_i y_i) = (a(x_i y_i)) = (x_i(ay_i)) = (x_i)(ay_i) = x(ay)$. Altogether A is an R-semi-algebra again. And as clearly $\mathrm{Supp}(xy) \subseteq \mathrm{Supp}(x) \cap \mathrm{Supp}(y)$ we get $xy \in S := \oplus_i A_i$ in case x and $y \in S$. Hence S is an R-sub-semi-algebra of P.

 Now suppose any A_i even is an R-algebra featuring the unit element 1_i. Then for any $x = (x_i) \in P$ we get $(1_i)x = (1_i)(x_i) = (1_i x_i) = (x_i) = x$ and $x(1_i) = (x_i)(1_i) = (x_i 1_i) = (x_i) = x$. That is (1_i) is the unit element of P again, such that P is an R-algebra, as well. Note however, that if $A_i \neq 0$ for infinitely many $i \in I$, then S is *not* an R-algebra, as $1 = (1_i) \in P \setminus S$ will not be contained in S.

- Now consider the R-module-homomorphisms $\varphi_i : M_i \to N$. By construction of S the map $\varphi := \bigoplus_i \varphi_i : S \to N$ is well-defined. And it also is an R-module-homomorphism, as for any $a \in R$ and for any $x = (x_i)$, $y = (y_i) \in S$ we get $\varphi(ax) = \sum_i \varphi_i(ax_i) = \sum_i a\varphi_i(x_i) = a\varphi(x)$ and $\varphi(x + y) = \sum_i \varphi_i(x_i + y_i) = \sum_i (\varphi_i(x_i) + \varphi_i(y_i)) = \varphi(x) + \varphi(y)$.

- (a) $\Longrightarrow$ (b): by definition of the arbitrary sum of the sub-modules P_i of M and by the assumption $M = \sum_i P_i$ we obtain the identity

$$M \;=\; \left\{ \sum_{i \in \Omega} x_i \;\middle|\; \Omega \subseteq I \text{ finite}, x_i \in P_i \right\}$$

Thus if we are given any $x \in M$ there are finitely many $x_i \in P_i$ ($i \in \Omega$) such that $x = \sum_i x_i$ Letting $x_i := 0$ for $i \in I \setminus \Omega$ we obtain an extension $(x_i) \in \bigoplus_i P_i$ satisfying $x = \sum_i x_i$. This proves the existence of such a representation. For the uniqueness suppose $\sum_i x_i = \sum_i y_i$ for some (x_i), $(y_i) \in \bigoplus_i P_i$. Fix any $j \in I$ and let

$$\widehat{x}_j := \sum_{i \neq j} x_i \quad \text{and} \quad \widehat{y}_j := \sum_{i \neq j} y_i \quad \in \quad \widehat{P}_j$$

Then we find $x_j - y_j = \widehat{y}_j - \widehat{x}_j$, but as $x_j - y_j \in P_j$ and $\widehat{y}_j - \widehat{x}_j \in \widehat{P}_j$ we have $x_j - y_j \in P_j \cap \widehat{P}_j = 0$, such that $x_j = y_j$. But as $j \in I$ has been arbitrary this means $(x_i) = (y_i)$, which also is the uniqueness.

- (b) $\implies$ (a): consider any $x \in M$, by asumption (b) there is some $(x_i) \in \bigoplus_i P_i$ such that $x = \sum_i x_i$. And as only finitely many x_i are non-zero this means $x = \sum_i x_i \in \sum_i P_i$. And as x has been arbitrary this already is $M = \sum_i P_i$. Now consider any $j \in I$ and any $x \in P_j \cap \widehat{P}_j$. As $x \in P_j$ we may let $\widetilde{x}_j := x_j \in P_j$ and $\widetilde{x}_i := 0 \in P_i$ (for $i \neq j$) to find $x = \sum_i \widetilde{x}_i$. On the other hand we have $x \in \widehat{P}_j$, that is there are some $x_i \in P_i$ such that $x = \sum_{i \neq j} x_i$. Finally let $x_j := 0$ then altogether this is $\sum_i x_i = \sum_{i \neq j} x_i = \sum_i \widetilde{x}_i$ and due to the uniqueness this means $x_i = \widetilde{x}_i$ for any $i \in I$. But by choice of $\widetilde{x}_i$ this is $x_i = 0$ for any $i \neq j$ and hence $x = \sum_{i \neq j} 0 = 0$, which had to be shown.

□

Proof of (3.30):
Let us again abbreviate the exterior direct product by $P := \prod_i M_i$ and the exterior direct sum by $S := \bigoplus_i M_i$. It is immediately clear that $\pi_j : P \to M_j$ is an R-module-homomorphism: $\pi_j(ax + y) = \pi_j((ax_i + y_i)) = ax_j + y_j = a\pi_j(x) + \pi_j(y)$ Analogously it is clear that ι_j is an R-module homomorphism. Also $\pi_j \iota_j(x_j) = \pi_j(\delta_{i,j} x_j) = \delta_{j,j} x_j = x_j$ such that $\pi_j \iota_j = \mathbb{1}$. And from this it immediately follows that π_j is surjective and that π_j is injective. Note that the latter could have also been seen directly. Now consider any $x = (x_i) \in P$, then by definition $\pi_i(x) = x_i$ such that $x = (x_i) = (\pi_i(x))$. Conversely consider $x = (x_i) \in S$, then by definition $\iota_j(x_j) = (\delta_{i,j} x_j)$ (where the index runs over all $i \in I$). Therefore a straightforard computation yields

$$\sum_{j \in I} \iota_j(x_j) \quad = \quad \sum_{j \in I} \Big(\delta_{i,j} x_j \Big) \quad = \quad \left(\sum_{j \in I} \delta_{i,j} x_j \right) \quad = \quad (x_i) \quad = \quad x$$

□

Proof of (3.34):

(i) It is easy to see that the map given is a homomorphism: $(x_i) + (y_i) = (x_i + y_i) \mapsto \sum_i (x_i + y_i) = (\sum_i x_i) + (\sum_i y_i)$ and $a(x_i) = (ax_i) \mapsto \sum_i (ax_i) = a(\sum_i x_i)$. And the bijectivity is just a reformulation of property (b) of inner direct sums.

(ii) Let us abbreviate the exterior direct sum by $M := \bigoplus_i M_i$. That is any $x \in M$ is of the form $x = (x_i)$ for some $x_i \in M_i$ of which only finitely many are non-zero. Thus $x = (x_i) = \sum_i \iota_i(x_i) \in \sum_i P_i$. And as x has been arbitrary this means $M = \sum_i P_i$. Now consider any $j \in I$ and any $x \in P_j \cap \widehat{P}_j$. As $x \in P_j = \iota_j(M_j)$ there is some $m_j \in M_j$ such that $(x_i) := x = \iota_j(m_j) = (\delta_{i,j} m_j)$. On the other hand there are $p_i \in P_i$ (where $i \neq j$) such that $x = \sum_{i \neq j} p_i$. Likewise we choose $n_i \in M_i$ such that

$p_i = \iota_i(n_i)$. If we finally let $n_j := 0$, then $x = \sum_{i\neq j} \iota_i(n_i) = \sum_i \iota_i(n_i) = (n_i)$. Comparing these two expressions of x we find $n_i = x_i = \delta_{i,j} m_j = 0$ for any $i \neq j$. And as also $n_j = 0$ this means $x = (n_i) = (0_i) = 0 \in M$. Therefore $P_j \cap \widehat{P}_j = 0$, as claimed.

□

Proof of (3.35):
First of all note that $P_i \leq_{\mathsf{m}} M_i$ and $M_i \leq_{\mathsf{m}} M$ implies $P_i \leq_{\mathsf{m}} M$, that is the P_i are sub-modules of M. And thereby their sum P is a sub-module of M, as well. We now prove that this sum even is direct: For this it suffices to show, that for any $j \in I$ we have

$$P_j \cap \widehat{P}_j \;=\; 0$$

But clearly $P_j \subseteq M_j$ and likewise $\widehat{P}_j \subseteq \widehat{M}_j$ and as M was assumed to be a direct sum of the M_i this implies $P_j \cap \widehat{P}_j \subseteq M_j \cap \widehat{M}_j = 0$, such that P is an inner direct sum of the P_i as well.
It remains to verify that $\Phi(x_i + P_i) = \sum_i x_i + P$ truly is a well-defined isomorphism of R-modules. First of all note, that all the sums in question always are finite, as we are speaking of direct sums only. Thus it makes sense to write $\sum_i x_i$ even if I is infinite. For the well-definedness we need to regard two sequences $(x_i + P_i) = (y_i + P_j)$, that is for any $i \in I$ we have $p_i := y_i - x_i \in P_i$. Thereby $\sum_i p_i \in P$ such that $\sum_i y_i - \sum_i x_i \in P$. But this again is $\sum_i x_i + P = \sum_i y_i + P$, as needed.
The surjectivity of Φ is straightforward: Given any $x \in M$ there are some $x_i \in M_i$ (where $i \in I$) such that $x = \sum_i x_i$. Then in particular we find

$$\Phi\big(x_i + P_i\big) \;=\; \left(\sum_{i\in I} x_i\right) + P \;=\; x + P$$

For the injectivity we consider $\sum_i x_i + P = \sum_i y_i + P$ or in other words $\sum_i (y_i - x_i) \in P$. Hereby $y_i - x_i \in M_i$ for any $i \in I$. Let us now denote the canonical projection (where $j \in I$)

$$\pi_j \;:\; M \;\to\; M_j \;:\; \sum_{i\in I} x_i \;\mapsto\; x_j$$

This is well-defined, since the x_i in the sum $\sum_i x_i \in M$ are uniquely determined (as M is an inner direct sum of the M_i). We now prove, that

$$\pi_j(P) \;=\; P_j$$

Clearly any $p_j \in P_j \subseteq M_j$ satifsies $\pi_j(p_j) = p_j$ such that $p_j \in \pi_j(P)$. Conversely, if $p \in P$ then by construction of P there are some $p_i \in P_i$ such that $p = \sum_i p_i$. Thereby $p_i \in P_i \subseteq M_i$ such that $\pi_j(p) = p_j \in P_j$. Thus we have proved $\pi_j(P) = P_j$. Once this is out of the way we apply π_j to $\sum_i (y_i - x_i) \in P$. As $y_i - x_i \in M_i$ we get

$$y_j - x_j \;=\; \pi_j\left(\sum_{i\in I} (y_i - x_i)\right) \;\in\; \pi_j(P) \;=\; P_j$$

and this is $y_j + P_j = x_j + P_j$. As $j \in I$ has been arbitrary we find that the entire sequences $(x_i + P_i) = (y_i + P_i)$ are equal, which means that Φ also is injective. Altogether Φ is an isomorphism. □

Proof of (3.37):

- Clearly the map $\varphi \mapsto (\pi_j \varphi \iota_i)$ is well-defined: as π_j and ι_i are R-module homomorphisms, so is the composition $\pi_j \varphi \iota_i : M_i \to N_j$. Conversely $(\varphi_{i,j}) \mapsto (\bigoplus_i \varphi_{i,j})$ is well-defined, too - it just is the cartesian product of the induced homomorphisms $\bigoplus_i \varphi_{i,j} : \bigoplus_i M_i \to N_j$.

- And it is also clear, that $\varphi \mapsto (\pi_j \varphi \iota_i)$ is a homomorphism of R-modules: as ι_i and π_j are homomorphisms of R-modules, so are the push-forward $\varphi \mapsto \varphi \iota_i$ and pull-back $\psi \mapsto \pi_j \psi$. Combining these we see that $\varphi \mapsto \pi_j \varphi \iota_i$ is a homomorphism of R-modules. Thus if we regard any $\varphi, \psi \in \mathrm{mhom}(M, N)$ and any $a \in R$, then $a\varphi + \psi \mapsto (\pi_j(a\varphi + \psi)\iota_i) = (a\pi_j \varphi \iota_i + \pi_j \psi \iota_i) = a(\pi_j \varphi \iota_i) + (\pi_j \psi \iota_i)$, as the composition in the direct product was defined to be component-wise.

- We will now prove that these maps are mutually inverse, we start by regarding $\varphi \mapsto (\pi_j \varphi \iota_i) \mapsto \psi := (\bigoplus_i \pi_j \varphi \iota_i)$. Thus consider an arbitrary $x = (x_i) \in \bigoplus_i M_i$ then we find

$$\psi(x) \;=\; \left(\sum_{i \in I} \pi_j \varphi \iota_i(x_i) \right) \;=\; \left(\pi_j \varphi \left(\sum_{i \in I} \iota_i(x_i) \right) \right)$$

 as $\pi_j \varphi$ is an R-module homomorphism. Now recall the identities $x = \sum_i \iota_i(x_i)$ and $y = (\pi_j(y))$, inserting these we obtain $\psi = \varphi$ from

$$\psi(x) \;=\; \Big(\pi_j \varphi(x) \Big) \;=\; \varphi(x)$$

- Thus we have to regard $(\varphi_{i,j}) \mapsto (\bigoplus_i \varphi_{i,j}) \mapsto (\psi_{i,j}) := (\pi_j(\bigoplus_i \varphi_{i,j})\iota_i)$. We need to verify that for any $i \in I$ and $j \in J$ we get $\varphi_{i,j} = \psi_{i,j}$. Thus fix any i, j and $x_i \in M_i$ and compute

$$\psi_{i,j}(x_i) \;=\; \pi_j \left(\left(\bigoplus_{a \in I} \varphi_{a,b} \right)_{b \in J} \Big(\iota_i(x_i) \Big) \right)$$

 By definition we have $\iota_i(x_i) = (\delta_{a,i} x_i)$, where the index runs over $a \in I$. Inserting this into the definition of $\bigoplus_a \varphi_{a,b}$ we continue

$$\psi_{i,j}(x_i) \;=\; \pi_j \left(\sum_{a \in I} \varphi_{a,b}(\delta_{a,i} x_i) \right)_{b \in J} \;=\; \sum_{a \in I} \varphi_{a,j}(\delta_{a,i} x_i)$$

 If $a \neq i$ then $\delta_{a,i} x_i = 0 \in M_a$ such that the respective summand vanishes. It only remains the summand of $a = i$, which is given to be $\varphi_{i,j}(\delta_{i,i} x_i) = \varphi_{i,j}(x_i)$. As x_i has been arbitrary this proves $\psi_{i,j} = \varphi_{i,j}$ which had to be shown.

- We now prove the claim in the remark to the proposition: that is we consider $\varphi_i := (\varphi_{i,j}) \in \bigoplus_j \mathrm{mhom}(M_i, N_j)$ and want to show that the image of the corresponding map $\varphi := (\bigoplus_i \varphi_{i,j})$ is contained in $\bigoplus_j N_j$. Thus consider any $x = (x_i) \in \bigoplus_i M_i$ then we have to verify, that

$$y \;:=\; \varphi(x) \;=\; \left(\sum_{i \in I} \varphi_{i,j}(x_i) \right) \;\in\; \bigoplus_{j \in J} N_j$$

 That is we have to verify that the support of y is finite. To see this let us abbreviate the support of x by $\Omega := \mathrm{Supp}(x) \subseteq I$, which is a finite set, as $x \in \bigoplus_i M_i$. Then it is clear that the support of

y satisfies the following inclusions

$$\begin{aligned}
\mathrm{Supp}(y) &= \left\{ j \in J \;\middle|\; \sum_{i\in I} \varphi_{i,j}(x_i) \neq 0 \right\} \\
&\subseteq \left\{ j \in J \mid \exists\, i \in I \;:\; \varphi_{i,j}(x_i) \neq 0 \right\} \\
&\subseteq \left\{ j \in J \mid \exists\, i \in I \;:\; x_i \neq 0 \text{ and } \varphi_{i,j} \neq 0 \right\} \\
&= \left\{ j \in J \mid \exists\, i \in \Omega \text{ with } \varphi_{i,j} \neq 0 \right\} \\
&= \bigcup \{\, \mathrm{Supp}(\varphi_i) \mid i \in \Omega \,\}
\end{aligned}$$

However the latter is a finite (Ω is finite) union of finite (any $\mathrm{Supp}(\varphi_i)$ was assumed to be finite) subsets of J. Hence it is a finite set itself which proves $y \in \bigoplus_j N_j$ which had been claimed.

□

Proof of (3.40):

(i) Recall that $\mathfrak{a}P$ has been defined to be the sub-module generated by elements of the form αp with $\alpha \in \mathfrak{a}$ and $p \in P$. In the light of (3.12) this turns into

$$\begin{aligned}
\mathfrak{a}P &= \mathrm{Lh}\{\, \alpha p \mid \alpha \in \mathfrak{a},\ p \in P \,\} \\
&= \left\{ \sum_{i=1}^{n} b_i \alpha_i p_i \;\middle|\; 1 \leq n \in \mathbb{N},\ b_i \in R,\ \alpha_i \in \mathfrak{a},\ p_i \in P \right\}
\end{aligned}$$

But as $\mathfrak{a}$ is an ideal and $\alpha_i \in \mathfrak{a}$ we find that $a_i := b_i\alpha_i \in \mathfrak{a}$ again. And hence $\mathfrak{a}P$ is contained in the set given in claim (i). Conversely any $a_1p_1 + \cdots + a_np_n$ can be realized by taking $b_1 = \cdots = b_n = 1$ and $\alpha_i = a_i$. Thus the set given in claim (i) is also contained in $\mathfrak{a}P$:

$$\mathfrak{a}P = \left\{ \sum_{i=1}^{n} a_i p_i \;\middle|\; 1 \leq n \in \mathbb{N},\ a_i \in \mathfrak{a},\ p_i \in P \right\}$$

(ii) As $x \in \mathfrak{a}P$ there are some $\alpha_1, \ldots, \alpha_m \in \mathfrak{a}$ and $q_1, \ldots, q_m \in P$ such that $x = \alpha_1q_1 + \cdots + \alpha_mq_m$ as we have seen in (i). In the first case let P be generated by $\{\, p_j \mid j \in J \,\}$, then the elements q_k can be written in the following form

$$q_k = \sum_{j\in J} b_{k,j} p_j$$

for some $b_{k,j} \in R$, of which only finitely many are non-zero. That is for any $k \in 1 \ldots m$ the set $J(k) := \{\, j \in J \mid b_{k,j} \neq 0 \,\}$ is finite. Inserting these equations into our presentation of x we find

$$x = \sum_{k=1}^{m} \alpha_k q_k = \sum_{k=1}^{m} \alpha_k \left(\sum_{j\in J} b_{k,j} p_j \right) = \sum_{j\in J} \left(\sum_{k=1}^{m} \alpha_k b_{k,j} \right) p_j$$

If $j \notin J(1) \cup \cdots \cup J(m)$ then $b_{k,j} = 0$ for any $k \in 1 \ldots m$. In this case the element $a_j := \sum_k \alpha_k b_{k,j}$ is zero and hence the sum is well-defined, as it only runs over the finite set $J(1) \cup \cdots \cup J(m)$. Also, as $\mathfrak{a}$ is an ideal all the elements a_j(for any $j \in J$) are contained in $\mathfrak{a}$ again. Let us denote the non-zero $a_j \in \mathfrak{a}$ by $a_1, \ldots, a_n$ and the corresponding p_j by $p_1, \ldots, p_n$, then we have arrived at the first claim $x = a_1p_1 + \cdots + a_np_n$.

In the second case R is commutative and we assume that $\mathfrak{a}$ is generated by the set $\{ a_i \mid i \in I \}$. Then any scalar α_k can be written in the following form

$$\alpha_k \;=\; \sum_{i\in I} b_{k,i}a_i$$

for some $b_{k,i} \in R$, of which only finitely many are non-zero. That is for any $k \in 1\ldots m$ the set $I(k) := \{ i \in I \mid b_{k,i} \neq 0 \}$ is finite. Inserting these equations into our presentation of x we find

$$x \;=\; \sum_{k=1}^{m} \alpha_k q_k \;=\; \sum_{k=1}^{m} \left(\sum_{i\in I} b_{k,i}a_i \right) q_k \;=\; \sum_{i\in I} a_i \left(\sum_{k=1}^{m} b_{k,i}q_k \right)$$

If $i \notin I(1) \cup \cdots \cup I(m)$ then $b_{k,i} = 0$ for any $k \in 1\ldots m$. In this case the element $p_i := \sum_k b_{k,i}q_k$ is zero and hence the sum is well-defined, as it only runs over the finite set $I(1) \cup \cdots \cup I(m)$. Also, as P is a sub-module all the elements p_i are contained in P again. Let us denote the non-zero $p_i \in P$ by $p_1, \ldots, p_n$ and the corresponding a_i by $a_1, \ldots, a_n$, then we have arrived at the second claim $x = a_1p_1 + \cdots + a_np_n$.

(iii) As $ap \in P$ for any $a \in \mathfrak{a} \subseteq R$ and any $p \in P$, so is the sub-module generated by these elements - and this is $\mathfrak{a}P$.

(iv) Considering the ideals $\mathfrak{a}$ and $\mathfrak{b}$ with $\mathfrak{a} \subseteq \mathfrak{b}$ we find that for any $a \in \mathfrak{a} \subseteq \mathfrak{b}$ and any $p \in P$ we get $ap \in \mathfrak{a}P$ and hence $\mathfrak{a}P \subseteq \mathfrak{b}P$. In complete analogy: Considering the submdules P and Q with $P \subseteq Q$ we find that for any $a \in \mathfrak{a}$ and any $p \in P \subseteq Q$ we get $ap \in \mathfrak{a}Q$ and hence $\mathfrak{a}P \subseteq \mathfrak{a}Q$.

(v) We first prove that $\mathfrak{a}(M/P)$ is contained in $(\mathfrak{a}M + P)/P$, to do this, consider any element of $\mathfrak{a}(M/P)$, by definition this is of the form (where $a_k \in \mathfrak{a}$ and $x_k \in M$)

$$\sum_{k=1}^{n} a_k(x_k + P) \;=\; \left(\sum_{k=1}^{n} a_k x_k \right) + P \;\in\; \mathfrak{a}M + P \Big/ P$$

That is $\mathfrak{a}(M/P) \subseteq (\mathfrak{a}M + P)/P$, conversely consider any element of $\mathfrak{a}M + P$, that is we are given any $a_k \in \mathfrak{a}$, $x_k \in M$ and $p \in P$, then

$$\begin{aligned} \left(\sum_{k=1}^{n} a_k x_k \right) + p + P \;&=\; \left(\sum_{k=1}^{n} a_k x_k \right) + P \\ &=\; \sum_{k=1}^{n} a_k(x_k + P) \;\in\; \mathfrak{a}\left(M \Big/ P \right) \end{aligned}$$

That is $(\mathfrak{a}M + P)/P \subseteq \mathfrak{a}(M/P)$ as well and hence we have proved the equality of these sets, which had been claimed.

(vi) By definition (3.14) of the quotient module $M/\mathfrak{a}M$ is a well-defined R-module. Hence all we have to do is checking the well-definedness of the scalar-multiplication. We will present two ways of demonstrating this: (1) clearly we get $a(x + \mathfrak{a}M) = ax + \mathfrak{a}M = 0 + \mathfrak{a}M$ for any $a \in \mathfrak{a}$ and any $x \in M$. That is $\mathfrak{a} \subseteq \operatorname{ann}_R(M/\mathfrak{a}M)$, such that we could simply cite (3.22.(v)). The more instructive way (2) is a direct computation however: consider $b + \mathfrak{a} = c + \mathfrak{a}$ and $x + \mathfrak{a}M = y + \mathfrak{a}M$, that is

$a := c - b \in \mathfrak{a}$ and $p := y - x \in \mathfrak{a}M$. Then $cy - bx = cy - by + by - bx = (c-b)y + b(y-x) = ay + bp$. But as $a \in \mathfrak{a}$ we find that $ay \in \mathfrak{a}M$ and as $p \in \mathfrak{a}M$ already we see that $cy - bx \in \mathfrak{a}M$. But this is $bx + \mathfrak{a}M = cy + \mathfrak{a}M$ and hence $(b + \mathfrak{a}, x + \mathfrak{a}M) \mapsto bx + \mathfrak{a}M$ does not depend on the specific choice of $b \in R$ or $x \in M$.

(vii) We first have to check the well-definedness of $\varphi/\mathfrak{a}$: to do this we consider any $x + \mathfrak{a}M = y + \mathfrak{a}M$ in $M/\mathfrak{a}M$, that is $p := y - x \in \mathfrak{a}M$. By definition of $\mathfrak{a}M$ this means that p can be written as $p = a_1p_1 + \cdots + a_np_n$ for some $a_i \in \mathfrak{a}$ and $p_i \in M$. Then we can compute

$$\varphi(y) - \varphi(x) \;=\; \varphi(p) \;=\; \sum_{i=1}^{n} a_i\varphi(p_i) \;\in\; \mathfrak{a}N$$

That is $\varphi(y) + \mathfrak{a}N = \varphi(x) + \mathfrak{a}N$, such that the map $\varphi/\mathfrak{a}$ truly is well-defined. The properties of being a homomorphism are straightforward: consider any $a \in R$ and any $x, y \in M$, then

$$\begin{aligned}
\varphi\left((a+\mathfrak{a})(x+\mathfrak{a}M)\right) &= \varphi(ax+\mathfrak{a}M) \;=\; \varphi(ax)+\mathfrak{a}N \\
&= a\varphi(x)+\mathfrak{a}N \;=\; (a+\mathfrak{a})\left(\varphi(x)+\mathfrak{a}N\right) \\
&= (a+\mathfrak{a})\varphi\left(x+\mathfrak{a}N\right) \\
\varphi\left((x+\mathfrak{a})+(y+\mathfrak{a}M)\right) &= \varphi\left((x+y)+\mathfrak{a}M\right) \;=\; \varphi(x+y)+\mathfrak{a}N \\
&= \varphi(x)+\varphi(y)+\mathfrak{a}N \\
&= \left(\varphi(x)+\mathfrak{a}N\right)+\left(\varphi(y)+\mathfrak{a}N\right)
\end{aligned}$$

(vii) If $\varphi : M \to N$ is surjective, then clearly $\varphi/\mathfrak{a} : M/\mathfrak{a}M \to N/\mathfrak{a}N$ is surjective as well: given any $y + \mathfrak{a}N \in N/\mathfrak{a}N$ we choose any $x \in M$ with $\varphi(x) = y$, then $(\varphi/\mathfrak{a})(x + \mathfrak{a}M) = \varphi(x) + \mathfrak{a}N = y + \mathfrak{a}N$.

If φ even is bijective, it remains to check the injectivity of $\varphi/\mathfrak{a}$. To do this we regard the following homomorphism of R-modules

$$\psi \;:\; M \to {}^{N}\Big/_{\mathfrak{a}N} \;:\; x \mapsto \varphi(x) + \mathfrak{a}N$$

That is $\psi = \pi\varphi$, where π denotes the canonical projection of N onto $N/\mathfrak{a}N$. Now by definition of ψ we see $\ker(\psi) = \{\, x \in M \mid \varphi(x) \in \mathfrak{a}N \,\}$ and therefore $\mathfrak{a}M \subseteq \ker(\psi)$. If conversely $\varphi(x) \in \mathfrak{a}N$, then $\varphi(x) = a_1y_1 + \cdots + a_ny_n$ for some $a_i \in \mathfrak{a}$ and $y_i \in N$. Yet as φ is bijective we may define $x_i := \varphi^{-1}(y_i)$, that is $y_i = \varphi(x_i)$ and hence

$$\varphi(x) \;=\; a_1\varphi(x_1) + \ldots a_n\varphi(x_n) \;=\; \varphi(a_1x_1 + \cdots + a_nx_n) \;\in\; \varphi(\mathfrak{a}M)$$

By the bijectivity of φ this means $x \in \mathfrak{a}M$ again, such that we have proved $\ker(\psi) = \mathfrak{a}M$. Now note that - by definiton of ψ - we have $(\varphi/\mathfrak{a})(x + \mathfrak{a}M) = \psi(x)$. Therefore

$$\ker\left(\varphi\Big/_{\mathfrak{a}}\right) \;=\; \ker(\psi)\Big/_{\mathfrak{a}M} \;=\; \mathfrak{a}M\Big/_{\mathfrak{a}M} \;=\; 0 \;\in\; M\Big/_{\mathfrak{a}M}$$

That is $\varphi/\mathfrak{a}$ has zero-kernel and hence is injective. As the surjectivity has already been proved we found the bijectivity of $\varphi/\mathfrak{a}$.

(viii) Consider any elements $z_1, \dots, z_n \in Z$, then by definition of the scalar multiplication on $M/\mathfrak{a}M$ we already see the identity

$$\sum_{i=1}^{n}(a_i + \mathfrak{a})z_i \quad \sum_{i=1}^{n} a_i z_i$$

And as in both cases the $a_i \in R$ can be chosen completely arbitrary this implies that the R-linear hull of Z equals the $(R/\mathfrak{a})$-linear hull.

(ix) Clearly Q is an R-sub-module of $M/\mathfrak{a}M$ if and only if Q equals its R-linear hull. Likewise Q is an $(R/\mathfrak{a})$-sub-module of $M/\mathfrak{a}M$ if and only if Q equals its $(R/\mathfrak{a})$-linear hull. But by (viii) these linear hulls are equal, and hence we get

$$\begin{aligned} Q \in \mathrm{Subm}_R\left(M \Big/ \mathfrak{a}M\right) &\iff \mathrm{Lh}_R(Q) = Q = \mathrm{Lh}_{R/\mathfrak{a}}(Q) \\ &\iff Q \in \mathrm{Subm}_{R/\mathfrak{a}}\left(M \Big/ \mathfrak{a}M\right) \end{aligned}$$

Now the explicit description of the $(R/\mathfrak{a})$-sub-modules of $M/\mathfrak{a}M$ is just an application of the correspondence theorem (3.16) of modules.

(x) Since $\mathfrak{a} \subseteq \mathfrak{b}$ it is clear from the definition that $\mathfrak{a}M \subseteq \mathfrak{b}M$. And as both $P := \mathfrak{a}M$ and $Q := \mathfrak{b}M$ are sub-modules of M the claim is nothing but the third isomorphism theorem of modules (3.78.(iv)) applied to this situation.

□

Proof of (3.46):

(i) We only need to show the well-definedness of the scalar multiplication: Hence let us consider any $x \in M_t$ and $a + tR = b + tR$. That is $b - a \in tR$, say $b - a = tu$ for some $u \in R$. Then $(b-a)x = tux = utx = u0 = 0$ and hence $bx = ax$. But this aleady is $(a + tR)x = (b + tR)x$.

(ii) Basically this is just an application of the first isomorphism theorem of modules (3.78.(ii)). Clearly both M_t and M_t are sub-modules, as they are defined as $M_t = \mathrm{kn}(\mu_t)$ and $tM = \mathrm{im}(\mu_t)$ respectively and the isomorphism claimed here is precisely the induced isomorphism in said theorem.

(iii) If $x \in M_t$ then $t\varphi(x) = \varphi(tx) = \varphi(0) = 0$ such that $\varphi(x) \in N_t$. This already is $\varphi(M_t) \subseteq N_t$. Let us now assume that φ is bijective, then we consider any $y \in N_t$, that is $ty = 0$. Now let $x := \varphi^{-1}(y) \in M$, then we have $\varphi(tx) = t\varphi(x) = ty = 0$ and thereby $tx = 0$, such that $x \in M_t$. That is we also have $y = \varphi(x) \in \varphi(M_t)$.

(iv) Consider any $x \in M_t \subseteq M$. By assumption x has a unique decomposition in terms of $x = \sum_i x_i$ where $x_i \in P_i$ for any $i \in I$. Then we have $0 = tx = t\sum_i x_i = \sum_i tx_i$ and as $tx_i \in P_i$ this is the unique decomposition of $0 \in M$ in terms of the P_i. Due to the uniqueness this is $tx_i = 0$ and hence $x_i \in (P_i)_t$. That is any $x \in M_t$ has a unique decomposition in terms of the $(P_i)_t$, which had to be shown.

(v) Let us first deal with the well-definedness of $t\varphi$. That is we consider any two $(r_i + a_iR) = (s_i + a_iR)$. That is we have $s_i - r_i \in a_iR$ for any $i \in I$ and multiplying this equation with t we get $ts_i - tr_i \in ta_iR = b_iR$. As this is true for any $i \in I$ we already have $(tr_i + b_iR) = (ts_i + b_iR)$ and thus $t\varphi$ is well-defined. Also the homomorphism properties of $t\varphi$ are plain to see.

So let us next assume, that φ is surjective, then we need to show that $t\varphi$ is surjective, as well. Given any $y \in tM$ we write $y = tx$ and choose $(r_i + b_iR)$ such that $\varphi(r_i + b_iR) = x$. Then we get

$$t\varphi\Big(r_i + a_iR\Big) \;=\; \varphi\Big(tr_i + b_iR\Big) \;=\; t\varphi\Big(r_i + b_iR\Big) \;=\; tx \;=\; y$$

Finally suppose that φ is injective and that $t \in \text{NZD}(R)$ is a non-zero-divisor, then we need to show that $t\varphi$ is injective, as well. So consider any $(r_i + a_iR)$ with $\varphi(tr_i + b_iR) = 0$. As φ is injective this leaves $(tr_i + b_iR) = 0$ which is $tr_i \in b_iR = ta_iR$ for any $i \in I$. But as $t \in \text{NZD}(R)$ this implies $r_i \in a_iR$ for any $i \in I$ and hence $(r_i + a_iR) = 0$.

(vi) In the first part we will check the well-definedness of the homomorphism $\varphi : a + sR \mapsto ra + tR$. Take a look at $a + sR = b + sR$, this means $b - a \in sR$ and thereby $rb - ra = r(b - a) \in rsR = tR$, such that $ra + tR = rb + tR$. Also we find that $s(ra + tR) = sra + tR = ta + tR = 0 + tR$ such that $ra + tR \in (R/tR)_s$ again. The R-linearity is clear, as well: $(a + sR) + (b + sR) = (a + b) + sR \mapsto r(a + b) + tR = (ra + tR) + (rb + tR)$ and $u(a + sR) = ua + sR \mapsto rua + tR = u(ra + tR)$.

Let us now assume that $t = rs \in \text{NZD}(R)$ is a non-zero-divisor of R. This implies that r and $s \in \text{NZD}(R)$ are non-zero-divisors, as well. And from this we can deduce the injectivity of φ: Suppose $0 + tR = \varphi(a + sR) = ra + tR$, this means $ra \in tR = rsR$ and as $r \in \text{NZD}(R)$ this again implies $a \in sR$ such that $a + sR = 0 + sR$. That is we have shown that $\varphi(a + sR) = 0 + tR$ implies $a + sR = 0 + sR$, which in turn implies the injectivity of φ.

For the surjectivity consider any $v + tR \in (R/tR)_s$ that is $s(v + tR) = 0 + tR$. In other words $sv \in tR = rsR = srR$ and as $s \in \text{NZD}(R)$, as well this again implies $v \in rR$. That is we have $v = ru$ for some $u \in R$. But then we find $\varphi(u + sR) = ru + tR = v + tR$, which already is the surjectivity.

(vii) For the implication " $\Longrightarrow$ " we have $1 + tR \in R/tR = (R/tR)_s$ and hence $0 + tR = s(1 + tR) = s + tR$ such that $s \in tR$. But this already is $t \mid s$. Conversely we start with $t \mid s$ and with the same reasoning arrive at $s + tR = 0 + tR$. Thus for any $a \in R$ we get $s(a + tR) = a(s + tR) = a(0 + tR) = 0 + tR$ such that $a + tR \in (R/tR)_s$. This is $R/tR \subseteq (R/tR)_s$ and the converse inclusion is trivial.

(viii) First of all $(R/tR)_p = 0$ is equivalent to saying $p(a + tR) = 0 + tR$ implies $a + tR = 0 + tR$ which again is equivalent to $a \in tR$. So let us start with $p \not\mid t$, then we are given some $a + tR$ with $p(a + tR) = 0 + tR$ and need to show $a \in tR$. By assumption we then have $pa \in tR$, that is $pa = tv$ for some $v \in R$. In particular $p \mid pa = tv$ which implies $p \mid t$ or $p \mid v$, since p is a prime element of R. But as also $p \not\mid t$ this only leaves $p \mid v$ and hence there is some $u \in R$ such that $pu = v$. Then we have $pa = tv = tpu$ and hence $a = tu$ since $p \in \text{NZD}(R)$. But this is $a \in tR$, which had to be shown.

Conversely if $p \mid t$, then by (iv) we have an isomorphism of the R-modules $R/pR \xrightarrow{\sim} (R/tR)_p$. As p is prime it is not a unit and hence $R/pR \neq 0$. Thus in turn we find $(R/tR)_p \neq 0$, as well.

□

Proof of (3.71):

(ii) If $x, y \in \ker(\varphi)$ then $\varphi(ax) = \alpha(a)\varphi(x) = \alpha(a)0 = 0$ and hence $ax \in \ker(\varphi)$ for any $a \in R$. Likewise $\varphi(x+y) = \varphi(x) + \varphi(y) = 0+0 = 0$, such that $x+y \in \ker(\varphi)$ as well. Hence $\ker(\varphi)$ is an R-sub-module of M. Now we have the assumption that α is surjective and consider any $u, v \in \operatorname{im}(\varphi)$, that is $u = \varphi(x)$ and $v = \varphi(y)$ for some $x, y \in M$. Then $u + v = \varphi(x) + \varphi(y) = \varphi(x+y) \in \operatorname{im}(\varphi)$. And if $b \in S$ then - due to the surjectivity of α - we may choose some $a \in R$ with $b = \alpha(a)$. Then $bu = \alpha(a)\varphi(x) = \varphi(ax) \in \operatorname{im}(\varphi)$ again, and hence $\operatorname{im}(\varphi)$ is an S-sub-module of N.

(iii) φ is surjective iff for any $y \in N$ there is some $x \in M$ such that $\varphi(x) = y$. In other words that is $N \subseteq \operatorname{im}(\varphi)$. But as $\operatorname{im}(\varphi) \subseteq N$ is true in any case, this is equivalent to $\operatorname{im}(\varphi) = N$.

Likewise φ is injective, iff for any $x, y \in M$ we get the implication $\varphi(x) = \varphi(y) \implies x = y$. But since φ is R-linear, this can also be put as $\varphi(y - x) = 0 \implies y - x = 0$. Let us now substitute $p = y - x$, then this is equivalent to: $\varphi(p) = 0 \implies p = 0$ for any $p \in M$. In other words that is $\ker(\varphi) \subseteq \{0\}$. But as as $\{0\} \subseteq \ker(\varphi)$ is true in any case, this is equivalent to $\ker(\varphi) = \{0\}$.

(iv) By definition $u, v \in \varphi^{-1}(Q)$ means $\varphi(u), \varphi(v) \in Q$. And as $0_N \in Q$ and $\varphi(0_M) = 0_N$ we find $0_M \in \varphi^{-1}(Q)$. If now $a \in R$, then $\varphi(au) = \alpha(a)\varphi(u) \in Q$, as Q is an S-sub-module of N. Therefore $au \in \varphi^{-1}(Q)$ again. Likewise $\varphi(u+v) = \varphi(u) + \varphi(v) \in Q$ such that $u + v \in \varphi^{-1}(Q)$, as well. Altogether $\varphi^{-1}(Q)$ is a sub-module of M.

By definition $x, y \in \varphi(P)$ means $x = \varphi(u)$ and $y = \varphi(v)$ for some $u, v \in P$. Again, as $0_M \in P$ and $\varphi(0_M) = 0_N$ we find $0_N \in \varphi(P)$. If $b \in S$, then (as α was assumed to be surjective) there is some $a \in R$ with $\alpha(a) = b$. But then we get $bx = \alpha(a)\varphi(u) = \varphi(au) \in \varphi(P)$, as $au \in P$, since P is a sub-module. Likewise $x + y = \varphi(u) + \varphi(v) = \varphi(u+v) \in \varphi(P)$, as $u + v \in P$, since P is a sub-module. Altogether $\varphi(P)$ is a sub-module of N.

(v) It suffices to check the general case, as the case of R-modules is included via $\alpha = \beta = \mathbb{1}$, that is by leaving out α and β. Consider any $x, y \in L$ and any $a \in R$, then it is easy to compute $\psi\varphi(ax+y) = \psi(\varphi(ax+y)) = \psi(\alpha(a)\varphi(x) + \varphi(y)) = \beta(\alpha(a))\psi(\varphi(x)) + \psi(\varphi(y)) = \beta\alpha(a)\psi\varphi(x) + \psi\varphi(x)$.

(vi) We have to prove that $\varphi + \psi$ and $a\varphi$ are homomorphisms of R-modules again. To do this consider any $x, y \in M$ and $b \in R$, then it is easy to compute $(\varphi+\psi)(bx+y) = \varphi(bx+y) + \psi(bx+y) = b\varphi(x) + \varphi(y) + b\psi(x) + \psi(y) = b(\varphi(x) + \psi(x)) + \varphi(y) + \psi(y) = b(\varphi+\psi)(x) + (\varphi+\psi)(y)$. And as R is commutative, we also get $(a\varphi)(bx+y) = a(b\varphi(x) + \varphi(y)) = ab\varphi(x) + a\varphi(y) = ba\varphi(x) + a\varphi(y) = b(a\varphi)(x) + (a\varphi)(y)$.

(vii) We have to prove that $\varphi + \psi$ and $a\varphi$ are α-module-homomorphisms again. To do this consider any $x, y \in M$, $a \in S$ and $b \in R$, then it is easy to compute $(\varphi+\psi)(bx+y) = \varphi(bx+y) + \psi(bx+y) = \alpha(b)\varphi(x) + \varphi(y) + \alpha(b)\psi(x) + \psi(y) = \alpha(b)(\varphi(x) + \psi(x)) + \varphi(y) + \psi(y) = \alpha(b)(\varphi+\psi)(x) + (\varphi+\psi)(y)$. And as S is commutative, we also get $(a\varphi)(bx+y) = a(\alpha(b)\varphi(x) + \varphi(y)) = a\alpha(b)\varphi(x) + a\varphi(y) = \alpha(b)a\varphi(x) + a\varphi(y) = \alpha(b)(a\varphi)(x) + (a\varphi)(y)$.

(viii) We already know by (v) that $\operatorname{end}(M)$ is an R-module under the point-wise addition and scalar multiplication. Also for any $\varphi, \psi \in \operatorname{end}(M)$ the composition $\varphi\psi$ is a homomorphism again, due to (iv), and hence $\varphi\psi \in \operatorname{end}(M)$ again. Trivially $\mathbb{1}_M$ satisfies the property of a unit element $\varphi\mathbb{1}_M = \varphi = \mathbb{1}_M\varphi$ for any $\varphi \in \operatorname{end}(M)$. It remains to check the distributivity: Consider any φ, ψ

and $\chi \in \mathrm{end}(M)$ and any $x \in M$, then [since the addition $+$ is point-wise] we find

$$\begin{aligned}
\varphi(\psi+\chi) \,:\, x &\mapsto \varphi\big(\psi(x)+\chi(x)\big) \\
&= \varphi(\psi(x)) + \varphi(\chi(x)) \\
&= (\varphi\psi + \varphi\chi)(x) \\
(\varphi+\psi)\chi \,:\, x &\mapsto \big(\varphi+\psi\big)\big(\chi(x)\big) \\
&= \varphi(\chi(x)) + \psi(\chi(x)) \\
&= (\varphi\chi + \psi\chi)(x)
\end{aligned}$$

(ix) First of all $Q := \Phi(P) \leq_{\mathsf{m}} M$ is a sub-module of M, according to (iv). And for any $x, y \in M$ we see that $x + P = y + P$ is equivalent to $y - x \in P$. But as Φ is injective, this is equivalent to $\Phi(y) - \Phi(x) = \Phi(y - x) \in \Phi(P) = Q$, which again is equivalent to $\Phi(x) + Q = \Phi(y) + Q$. That is we have proved the well-definedness and injectivity of $x + P \mapsto \Phi(x) + Q$ at the same time. But as Φ is surjective, so is $x + P \mapsto \Phi(x) + Q$, altogether this is an isomorphism of R-modules.

(x) The properties of an R-module-homomorphism are easy to see, if $a \in R$ and $(a_x), (b_x) \in R^{\oplus X}$ then $\varrho(a(b_x)) = \varrho(ab_x) = \sum_x (ab_x)x = a\sum_x b_x x = a\varrho(b_x)$, by construcion of $R^{\oplus X}$, refer to (3.60) for details. Likewise we compute $\varrho((a_x) + (b_x)) = \varrho(a_x + b_x) = \sum_x (a_x + b_x)x = \sum_x a_x x + \sum_x b_x x = \varrho(a_x) + \varrho(b_x)$. And $\mathrm{im}(\varrho) = \mathrm{Lh}_R(X)$ is clear from the definition of $\mathrm{Lh}_R(X)$ and the construction of ϱ. Now ϱ is surjective, iff $\mathrm{Lh}_R(X) = \mathrm{im}(\varrho) = N$ and in the light of (3.61.(ii)) this is precisely the definiton that X generates M. Also we have seen that ϱ is injective, iff $\mathrm{kn}(\varrho) = 0$ and by construction of ϱ this means $\sum_x a_x x = 0 \implies \forall\, x \in X : a_x = 0$. This again is the R-linear independence of X. If ϱ is bijective, then any $x \in M$ has a unique representation $(a_x) \in R^{\oplus X}$ with $x = \varrho(a_x) = \sum_x a_x x$. And by (3.61.(vi)) this is equivalent to X being an R-basis of M.

□

Proof of (3.72):
In (i) the one direction: $\varphi = \psi$ implies $\varphi(x) = \psi(x)$ for any $x \in X$ is trivial. Conversely consider any $y \in M$. As X generates M there are some $x_i \in X$ and $a_i \in R$ such that $y = a_1 x_1 + \cdots + a_n x_n$. Now by the R-linearity of φ and ψ we find

$$\begin{aligned}
\varphi(y) &= \varphi\left(\sum_{i=1}^{n} a_i x_i\right) = \sum_{i=1}^{n} a_i \varphi(x_i) \\
&= \sum_{i=1}^{n} a_i \psi(x_i) = \varphi\left(\sum_{i=1}^{n} a_i x_i\right) = \psi(y)
\end{aligned}$$

And as $y \in M$ has been chosen arbitarily we have in fact proved $\varphi = \psi$. So it remains to prove statement (ii). As B is a basis of M it is clear - due to(3.61.(vi)) - that the representation $y = \sum_x a_x x$ is unique and hence φ is a well-defined map. It also is easy to see that this φ is R-linear (see below). But from this we already get the uniqueness, due to (i). As to R-linearity: given $u \in R$ and $y = \sum_x a_x x$ and $z = \sum_x b_x x \in M$ we clearly see that

$$\varphi(uy) = \varphi\left(\sum_{x \in B} u a_x x\right)$$

$$
\begin{aligned}
&= \sum_{x\in B} u a_x n(x) \;=\; u \sum_{x\in B} a_x n(x) \;=\; u\varphi(y)\\
\varphi(y+z) &= \varphi\left(\sum_{x\in B}(a_x+b_x)x\right)\\
&= \sum_{x\in B} a_x n(x) + \sum_{x\in B} b_x n(x) \;=\; \varphi(y)+\varphi(z)
\end{aligned}
$$

□

Proof of (3.73):
We have to prove that the push-forward ψ_* and pull-back φ^* truly are homomorphisms again. As (i) is contained in (iii) and likewise (ii) is contained in (iv) (as $\alpha = \beta = \mathbb{1}$ we just have to omit α and β) we will prove the latter two claims only. For (iii) we pick up any $a \in S$ and φ, $\varphi' \in \mathrm{mhom}_\alpha(L,M)$. Then for any $x \in L$ we get $\psi_*(a\varphi+\varphi')(x) = \psi(a\varphi(x)+\varphi'(x)) = \beta(a)\psi\varphi(x)+\psi\varphi(x) = (\beta(a)\psi\varphi+\psi\varphi')(x)$. And as this is true for any $x \in L$ we got $\psi_*(a\varphi+\varphi') = \beta(a)\psi\varphi+\psi\varphi' = \beta(a)\psi_*(\varphi)+\psi_*(\varphi')$. For (iv) the reasoning is quite similar, pick up any $b \in T$ and ψ, $\psi' \in \mathrm{mhom}_\beta(L,N)$. Then for any $x \in L$ we get $\varphi^*(b\psi+\psi')(x) = (b\psi+\psi')(\varphi(x)) = b\psi\varphi(x)+\psi'\varphi(x) = (b\psi\varphi+\psi'\varphi)(x)$. And as this is true for any $x \in L$ we get $\varphi^*(b\psi+\psi') = b\psi\varphi+\psi'\varphi = b\varphi^*(\psi)+\varphi^*(\psi')$. □

Proof of (3.74):
In the first part we need to show the claim $\mathrm{im}(\pi) = \{\, x \in M \mid \pi(x) = x \,\}$. The inclusion " $\supseteq$ " is trivial, if $x \in M$ satisfies $x = \pi(x)$, then $x \in \mathrm{im}(\pi)$ already. Conversely, if $x \in \mathrm{im}(\pi)$ then there is some $u \in M$ such that $x = \pi(u)$. But by assumption this yields $\pi(x) = \pi^2(u) = \pi(u) = x$.
For the second part, we have to prove, that M is the inner direct product of $\mathrm{im}(\pi)$ and $\mathrm{kn}(\pi)$. But clearly for any $x \in M$ we have $x = \pi(x) + x - \pi(x)$. Thereby $x \in \mathrm{im}(\pi)$ is clear and since $\pi(x-\pi(x)) = \pi(x)-\pi^2(x) = \pi(x)-\pi(x) = 0$ we also have $x-\pi(x) \in \mathrm{kn}(\pi)$. Thus we have established $M = \mathrm{im}(\pi)+\mathrm{kn}(\pi)$. On the other hand if $u \in \mathrm{im}(\pi)\cap\mathrm{kn}(\pi)$, then these properties mean $u = \pi(x)$ for some $x \in M$ and $\pi(u) = 0$. Therefore $0 = \pi(u) = \pi^2(x) = \pi(x) = u$, such that $\mathrm{im}(\pi)\cap\mathrm{kn}(\pi) = 0$. Together this means $M = \mathrm{im}(\pi)\oplus\mathrm{kn}(\pi)$. □

Proof of (3.76):

(i) The linearity can be seen with a simple computation based on the compositions of R^2: consider a, b, x and $y \in R$ all elements of R, then $\alpha((a,b)+(x,y)) = \alpha(a+x,b+y) = (a+x)+(b+y) = (a+b)+(x+y) = \alpha(a,b)+\alpha(x,y)$. Likewise $\alpha(a(x,y)) = \alpha(ax,ay) = ax+ay = a(x+y) = a\alpha(x,y)$. However - for example in the case $R = \mathbb{Z}$ - we have $\alpha(2\cdot 1,1) = \alpha(2,1) = 2+1 = 3$, whereas $2\alpha(1,1) = 2(1+1) = 2\cdot 2 = 4$. That is in the case $R = \mathbb{Z}$ we see that α is definitely not multilinear.

(ii) In this case the multi-linearity follows from the definition of the compositions on R^2: $\mu(a+b,x) = (a+b)x = ax+bx = \mu(a,x)+\mu(b,x)$ and $\mu(ax,y) = (ax)y = a(xy) = a\mu(x,y)$. Likewise we see that $\mu(a,x+y) = \mu(a,x)+\mu(a,y)$ and $\mu(x,ay) = a\mu(x,y)$ due to the commutativity of R. Hence μ is R-multilinear but in the case $R = \mathbb{Z}$ again definitely not R-linear: $\mu(2\cdot(1,1)) = \mu(2,2) = 2\cdot 2 = 4$, whereas $2\mu(1,1) = 2(1\cdot 1) = 2\cdot 1 = 2$.

(iii) The R-linearity is well known and a direct consequence of the definition of the compositions on R^2: $\pi_2((a,b)+(x,y)) = \pi_2(a+x,b+y) = b+y = \pi_2(a,b)+\pi_2(x,y)$ and likewise $\pi_2(a(x,y)) =$

$\pi_2(ax, ay) = ay = a\pi_2(x, y)$. Hence π_2 is R-linear, but in the case $R = \mathbb{Z}$ again not R-linear, since: $\pi_2(3, 1) = 1 \neq 3 = 3\pi_2(1, 1)$.

(iv) is purely definitional.

(v) The additivity of $(A, B) \mapsto AB$ was proved in (4.8.(ii)). The first argument $A \mapsto AB$ thereby clearly is R-linear, since $aA \mapsto (aA)B = a(AB)$, for the second argument $B \mapsto AB$ we need that R is commutative, since $bB \mapsto A(bB) = (Ab)B = (bA)B = b(AB)$.

□

Proof of (3.77):
For the implication (a) $\Longrightarrow$ (b) it suffices to prove, that the inverse map $\Psi := \Phi^{-1} : N \to M$ is a homomorphism of R-modules again. Regard any $u, v \in M$ and let $x := \Phi(u)$ and $y := \Phi(v)$. Then we compute $\Phi^{-1}(x + y) = \Phi^{-1}(\Phi(u) + \Phi(v)) = \Phi^{-1}\Phi(u + v) = u + v = \Phi^{-1}(x) + \Phi^{-1}(y)$. Thus Φ^{-1} respects the addition. And for any $a \in R$ we also find that $\Phi^{-1}(ax) = \Phi^{-1}(a\,\Phi(u)) = \Phi^{-1}\Phi(au) = au = a\,\Phi^{-1}(x)$. Thus Φ^{-1} also respects the scalar multiplication and thereby is a homomorphism of R-modules. The converse implication (b) $\Longrightarrow$ (a) is clear, in particular Ψ is an inverse mapping of Φ. The implication (b) $\Longrightarrow$ (c) is trivial - just let $\alpha := \Psi$ and $\beta := \Psi$. And for the converse (c) $\Longrightarrow$ (a) we simply compute: $\alpha = \alpha\mathbb{1}_N = \alpha(\Phi\beta) = (\alpha\Phi)\beta = \mathbb{1}_M\beta = \beta$. Thus letting $\Psi := \alpha = \beta$ we have $\Psi = \Phi^{-1}$, such that Φ is bijective. □

Proof of (3.78):

(i) We will first prove the well-definedness of $\overline{\varphi}$: if $x + P = y + P$, then $y - x \in P \subseteq \varphi^{-1}(Q)$ and hence $\varphi(y) - \varphi(x) = \varphi(y - x) \in Q$. This again is $\varphi(y) + Q = \varphi(x) + Q$, which had to be shown. To prove that $\overline{\varphi}$ is an R-module-homomorphism can be done in a straightforward computation: let $a \in R$ and $x, y \in M$, then

$$\begin{aligned}
\overline{\varphi}\,(a(x + P) + (y + P)) &= \overline{\varphi}((ax + y) + P) = \varphi(ax + y) + Q \\
&= (a\varphi(x) + \varphi(y)) + Q \\
&= a\,(\varphi(x) + Q) + (\varphi(y) + Q) \\
&= a\overline{\varphi}(x + P) + \overline{\varphi}(y + P)
\end{aligned}$$

(ii) First of all, let us abbreviate $K := \mathrm{kn}(\varphi)$. Then $\overline{\varphi}$ is well-defined, since if $x + K = y + K$, then $k := y - x \in K$ and hence - as $\varphi(k) = 0$

$$\overline{\varphi}(y + K) = \varphi(y) = \varphi(x + k) = \varphi(x) + \varphi(k) = \varphi(x) = \overline{\varphi}(x + K)$$

That $\overline{\varphi}$ is an R-module homomorphism can be shown in complete analogy to the argument used in (i):

$$\begin{aligned}
\overline{\varphi}\,(a(x + K) + (y + K)) &= \overline{\varphi}((ax + y) + K) = \varphi(ax + y) \\
&= a\varphi(x) + \varphi(y) = a\overline{\varphi}(x + K) + \overline{\varphi}(y + K)
\end{aligned}$$

By construction we have $\mathrm{im}(\overline{\varphi}) = \mathrm{im}(\varphi)$, such that the surjectivity of $\overline{\varphi}$ is trivial. It suffices to check

the injectivity: so let us regard any $x, y \in M$ such that $\varphi(x) = \overline{\varphi}(x+K) = \overline{\varphi}(y+K) = \varphi(y)$. That is $\varphi(y-x) = \varphi(y) - \varphi(x) = 0$ and hence $y - x \in \mathsf{kn}(\varphi) = K$, such that $x + K = y + K$.

(iii) Consider the canonical projection $\pi : M \to M/P$ given by $\pi(x) = x + P$. Let us denote the restricion of π to Q by φ, that is $\varphi : Q \to M/P : x \mapsto x + P$. Then we get

$$\begin{array}{rcccl} \mathsf{kn}(\varphi) & = & \{\, x \in Q \mid x \in P \,\} & = & P \cap Q \\ \mathsf{im}(\varphi) & = & \{\, x + P \mid x \in Q \,\} & = & {}^{P+Q}\big/_{P} \end{array}$$

So by the 1st isomorphism theorem φ induces an isomorphism $\overline{\varphi} : Q/\mathsf{kn}(\varphi) \xrightarrow{\sim} \mathsf{im}(\varphi)$, given to be $\overline{\varphi}(x + \mathsf{kn}(\varphi)) = x + P$ and this is precisely the isomorphism given in the claim.

(iv) Consider the identity $\mathbb{1} : M \to M$ on M. As $P \subseteq Q = \mathbb{1}^{-1}(Q)$ the identity induces the map $\varphi : M/P \to M/Q : x + P \mapsto x + Q$, according to (i). For this homomorphism it is clear, that

$$\begin{array}{rcccl} \mathsf{kn}(\varphi) & = & \{\, x + P \in Q \mid x \in Q \,\} & = & {}^{Q}\big/_{P} \\ \mathsf{im}(\varphi) & = & \{\, x + Q \mid x \in M \,\} & = & {}^{M}\big/_{Q} \end{array}$$

So by the 1st isomorphism theorem φ induces an isomorphism $\overline{\varphi} : (M/P)/\mathsf{kn}(\varphi) \xrightarrow{\sim} \mathsf{im}(\varphi)$, given to be $\overline{\varphi}((x + P) + \mathsf{kn}(\varphi)) = x + Q$, and this is precisely the inverse of the isomorphism given in the claim.

□

Proof of (3.80):
We will prove the equivalences by going from bottom to top, in circles, starting with (c) $\implies$ (b): Let $Q := \mathsf{kn}(\pi)$, then due to the assumption $P = \mathsf{im}(\pi)$ we get $M = \mathsf{im}(\pi) \oplus \mathsf{kn}(\pi) = P \oplus Q$ according to (3.74).
(b) $\implies$ (a): By assumption $M = P + Q$ any $x \in M$ can be written in the form $x = p + q$ for some $p \in P$ and $q \in Q$. And this decomposition is unique since $P \cap Q = 0$. Thus we get a well-defined homomorphism of modules by letting

$$\Phi \;:\; M \to P \oplus {}^{M}\big/_{P} \;\; x \mapsto (p,\; x + P)$$

Clearly any $p \in P$ has the decomposition $p = p + 0 \in P + Q$ such that $\Phi(P) = P \times \{\, 0 + P \,\}$. But this homomorphism also is injective: Suppose $\Phi(x) = 0 = (0, 0 + P)$ where $x = p + q$. Then this would mean $p = 0$ and $x + P = 0 + P$. The latter equation means $x \in P$, but as also $x = 0 + q \in Q$ we have $x \in P \cap Q = 0$ such that $x = 0$ itself. It remains to prove, that Φ also is surjective: Consider any $(u, v + P)$ in $P \oplus M/P$, then we decompose $v = p + q \in P + Q$ and define $x := u + q$. Then we get $x + P = u + q + P = p + q + P = v + P$ since $p - u \in P$. But thereby $\Phi(x) = (u, x + P) = (u, v + P)$.
(a) $\implies$ (c): Let us denote the canonical projection onto the first component by $\alpha : P \oplus M/P \to P \oplus M/P : (p, q + P) \mapsto (p, 0 + P)$. Then clearly $\alpha^2 = \alpha$ and we may define $\pi := \Phi^{-1}\alpha\Phi : M \to M$. This π is a homomorphism, since it is a composition of such and we immediately find

$$\pi^2 \;=\; \Phi^{-1}\alpha\Phi\Phi^{-1}\alpha\Phi \;=\; \Phi^{-1}\alpha^2\Phi \;=\; \Phi^{-1}\alpha\Phi \;=\; \pi$$

Thus π is a projection, too and it only remains to prove $\mathrm{im}(\pi) = P$. To see this consider any $x \in M$ and let us denote $(p, q+P) := \Phi(x)$. Then $\pi(x) = \Phi^{-1}\alpha(p, q+P) = \Phi^{-1}(p, 0+P)$ such that $\Phi\pi(x) = (p, 0+P) \in P \times \{\, 0+P \,\} = \Phi(P)$. As Φ is injective this implies $\pi(x) \in P$ such that we have established $\mathrm{im}(\pi) \subseteq P$. Conversely consider any $p \in P$, then by assumption we have $\Phi(p) \in \Phi(P) = P \times \{\, 0+P \,\}$, that is there is some $u \in P$ such that $\Phi(p) = (u, 0+P)$. Now compute $\pi(p) = \Phi^{-1}\alpha\Phi(p) = \Phi^{-1}\alpha(u, 0+P) = \Phi^{-1}(u, 0+P) = p$. In particular $p = \pi(p) \in \mathrm{im}(\pi)$ such that $P \subseteq \mathrm{im}(\pi)$, as well. □

Proof of (3.165):

(i) We basically only have to check the well-definedness of the composition: Given two elements (x_i) and (y_i) of the inverse limit, we have to check, that $(x_i y_i)$ is an element of the inverse limit, again. But for any $i \leq j \in I$ we find $\gamma_j^i(x_j y_j) = \gamma_j^i(x_j)\gamma_j^i(y_j)$ as γ_j^i is a homomorphism of groups and $\gamma_j^i(x_j)\gamma_j^i(y_j) = x_i y_i$, by assumption on the (x_i), (y_i). All the properties associativity, commutativity, neutral and inverse elements, are inherited by the direct product of the G_i generally, for obvious reasons. Thus the inverse limit is a (commutative) group, again.

(ii) By (i) the inverse limit of the M_i is a commutative group under addition $+$ again. We have to check the well-definedness of the scalar multiplication. As before in (i), we get $\mu_j^i(a x_j) = a\mu_j^i(x_j) = a x_i$ for any $a \in R$ and (x_i) in the inverse limit. This time, as μ_j^i was also assumed to be R-linear. Thus $(a x_i)$ is another element of the inverse limit and hence this is an R-sub-module of the direct product of the M_i.

(iii) By (i) the inverse limit of the R_i is a commutative group under addition $+$ again. And (i) also shows, that the inverse limit is a monoid under multiplication $\cdot$. Thus the inverse limit is a sub-ring of the direct product of the R_i and thereby a (commutative) ring, in itself.

(iv) Is an immediate consequence of (ii) - which turns the inverse limit into an R-module - and (iii) - which turns the inverse limit into a (commutative) ring. Thus the inverse limit is an R-sub-algebra of the direct product of the A_i and thereby an R-algebra in itself.

(v) As before let X_∞ abbreviate the inverse limit of (X_i, f_j^i). In a first step we prove, that $\mathcal{W}$ is a base of some topology: As for any $i \in I$ we have $\pi_i^{-1}(X_i) = X_\infty$ already, $\mathcal{W}$ covers X_∞. Fix some point $x \in X_\infty$ and consider base sets such that $x \in \pi_i^{-1}(U_i) \cap \pi_j^{-1}(U_j)$. We have to find a base set $\pi_k^{-1}(V) \in \mathcal{W}$ in between $x \in \pi_k^{-1}(V) \subseteq \pi_i^{-1}(U_i) \cap \pi_j^{-1}(U_j)$. As I is a net, there is some $k \in I$ with $k \geq i$ and $k \geq j$. Now define

$$V \;:=\; (f_k^i)^{-1}(U_i) \cap (f_k^j)^{-1}(U_j) \;\subseteq\; X_k$$

As the f_j^i are continuous, V is an open subset of X_k. And as $f_k^i \pi_k = \pi_i$ and likewise $f_k^j \pi_k = \pi_j$ we can compute

$$\begin{aligned} \pi_k^{-1}(V) &= \pi_k^{-1}(f_k^i)^{-1}(U_i) \cap \pi_k^{-1}(f_k^j)^{-1}(U_j) \\ &= (f_k^i \pi_k)^{-1}(U_i) \cap (f_k^j \pi_k)^{-1}(U_j) \\ &= \pi_i^{-1}(U_i) \cap \pi_j^{-1}(U_j) \end{aligned}$$

In particular $\pi_k^{-1}(V) \subseteq \pi_i^{-1}(U_i) \cap \pi_j^{-1}(U_j)$ and $x \in \pi_k^{-1}(V)$, such that $\mathcal{W}$ is the base of some topology, according to (6.12.(iii)). Now a set $C \subseteq X_\infty$ is closed, iff $C = X_\infty \setminus U$ for some open subset $U \subseteq X_\infty$. And by construction U has to be the union of open base sets taken from $\mathcal{W}$. That is there has to be some index set Λ such that $U_\lambda \subseteq X_{i(\lambda)}$ are open subsets, such that U is the union of $\pi_{i(\lambda)}^{-1}(U_\lambda)$. Let $C_\lambda := X_{i(\lambda)} \setminus U_\lambda$, then we compute

$$\begin{aligned} C &= X_\infty \setminus U = X_\infty \setminus \bigcup_{\lambda\in\Lambda} \pi_{i(\lambda)}^{-1}(U_\lambda) \\ &= \bigcap_{\lambda\in\Lambda} \pi_{i(\lambda)}^{-1}(C_\lambda)) = \bigcap_{i\in I} \bigcap_{i(\lambda)=i} \pi_i^{-1}(C_\lambda) \\ &= \bigcap_{i\in I} \pi_i^{-1}\left(\bigcap_{i(\lambda)=i} C_\lambda \right) \end{aligned}$$

So if we let C_i be the intersection of all C_λ with $i(\lambda) = i$ (that is $C_i = X_i$ in case there is no $\lambda \in \Lambda$ with $i(\lambda) = i$), then C is precisely of the form given in the claim.

□

Proof of (3.167):
We need to verify, that $\sim$ is an equivalence relation on $\mathcal{M}$, that is reflexive, symmetric and transitive: For any $i \in I$ and any $x \in M_i$ we have $\varphi_i^i(x) = x = \varphi_i^i(x)$ and hence $(i,x) \sim (i,x)$, which is the reflexivity. And for any $i, j \in I$ and any $x \in M_i$ and $y \in M_j$ such that $(i,x) \sim (j,y)$ there is some $p \geq i, j$ such that $\varphi_i^p(x) = \varphi_j^p(y)$. But this is $\varphi_j^p(y) = \varphi_i^p(x)$, which is the symmetry $(j,y) \sim (i,x)$. And if $(j,y) \sim (k,z)$, as well, then again there is some $q \in I$ with $j, k \leq q$ and $\varphi_j^q(y) = \varphi_k^q(z)$. Now choose some $r \in I$ with $p, q \leq r$, then we get $(i,x) \sim (k,z)$ from

$$\varphi_i^r(x) = \varphi_p^r\varphi_i^p(x) = \varphi_p^r\varphi_j^p(y) = \varphi_j^r(y) = \varphi_q^r\varphi_j^q(y) = \varphi_q^r\varphi_k^q(z) = \varphi_k^r(z)$$

That is $\sim$ also is transitive, altogether an equivalence relation. Let us also prove the commutativity of the diagram $\varepsilon_j\varphi_i^j = \varepsilon_i$ for any $i \leq j$: Consider any $x \in M_i$ and let $k := j$ and $y := \varphi_i^j(x) \in M_j$. Then $\varphi_i^k(x) = y = \varepsilon_j^k(y)$ and hence $(i,x) \sim (j,y)$. That is $\varepsilon_i(x) = [i,x] = [j,y] = [j,\varphi_i^j(x)] = \varepsilon_j\varphi_i^j(x)$ and hence $\varepsilon_i = \varepsilon_j\varphi_i^j$, as this is true for any $x \in M_i$. □

Proof of (3.168):

(i) Let us abbreviate $G_\infty := \varinjlim (G_i, \gamma_i^j)$. First of all we have to verify, that the composition $[i,x][j,y] := [k, \gamma_i^k(x)\gamma_j^k(y)]$ for some $k \geq i, j$ is well-defined: Consider any $(i_1,x_1) \sim (i_2,x_2)$ and $(j_1,y_1) \sim (j_2,y_2)$, then we have to show that $[i_1,x_1] + [j_1,y_1] = [i_2,x_2] + [j_2,x_2]$. By assumption we have some $p \geq i_1, i_2$ such that $\gamma_{i_1}^p(x_1) = \gamma_{i_2}^p(x_2)$ and some $q \geq j_1, j_2$ such that $\gamma_{j_1}^q(y_1) = \gamma_{j_2}^q(y_2)$. By definition $[i_1,x_1] + [j_1,y_1]$ is $[r_1, \gamma_{i_1}^{r_1}(x_1) + \gamma_{j_1}^{r_1}(y_1)]$ for some $r_1 \geq i_1, j_1$. Likewise there had to be some $r_2 \geq i_2, j_2$ such that $[i_2,x_2] + [j_2,y_2]$ has been defined, as $[r_2, \gamma_{i_2}^{r_2}(x_2) + \gamma_{j_2}^{r_2}(y_2)]$. Pick up any $s \geq r_1, r_2$ and $s \geq p, q$ then we compute

$$\gamma_{i_1}^s(x_1) = \gamma_p^s\gamma_{i_1}^p(x_1) = \gamma_p^s\gamma_{i_2}^p(x_2) = \gamma_{i_2}^s(x_2)$$

$$\gamma_{j_1}^s(y_1) = \gamma_q^s\gamma_{j_1}^q(y_1) = \gamma_q^s\gamma_{j_2}^q(y_2) = \gamma_{j_2}^s(y_2)$$

And from this we get

$$\gamma^s_{r_1}\big(\gamma^{r_1}_{i_1}(x_1)+\gamma^{r_1}_{j_1}(y_1)\big)=\gamma^s_{i_1}(x_1)+\gamma^s_{j_1}(y_1)=\gamma^s_{i_2}(x_2)+\gamma^s_{j_2}(y_2)=\gamma^s_{r_2}\big(\gamma^{r_2}_{i_2}(x_2)+\gamma^{r_2}_{j_2}(y_2)\big)$$

But this is $(r_1,\gamma^{r_1}_{i_1}(x_1)+\gamma^{r_1}_{j_1}(y_1))\sim(r_2,\gamma^{r_2}_{i_2}(x_2)+\gamma^{r_2}_{j_2}(y_2))$ and hence the composition on G_∞ is well-defined. All the properties associativity, commutativity, neutral and inverse elements, are inherited by G_∞ for obvious reasons: We check the associativity first: Given $[i,x]$, $[j,y]$ and $[k,z]$ choose $r\geq i,\,j$ and $s\geq r,\,k$, then we compute

$$\begin{aligned}\Big([i,x][j,y]\Big)[k,z] &= [r,\gamma^r_i(x)\gamma^r_j(y)][k,z] = [s,\gamma^s_r(\gamma^r_i(x)\gamma^r_j(y))\gamma^s_k(z)]\\ &= [s,(\gamma^s_i(x)\gamma^s_j(y))\gamma^s_k(z)] = [s,\gamma^s_i(x)(\gamma^s_j(y)\gamma^s_k(z))]\\ &= [s,\gamma^s_i(x)][s,\gamma^s_j(y)\gamma^s_k(z)] = [i,x]\Big([j,y][k,z]\Big)\end{aligned}$$

The commutativity of G_∞ (supposed all the G_i are commutative) is clear. For any $i\in I$ we have $[i,e_i][j,y]=[k,\gamma^k_i(e_i)\gamma^k_j(y)]=[k,e_k\gamma^k_j(y)]=[k,\gamma^k_j(y)]=[j,y]$ and this means that $[i,e_i]$ is a neutral element of G_∞. And clearly $[i,x][i,x^{-1}]=[i,xx^{-1}]=[i,e_i]$ (likewise $[i,x^{-1}][i,x]=[i,e_i]$) such that $[i,x^{-1}]$ is the inverse element of $[i,x]$. Altogether G_∞ is a (commutative) group again.

(ii) By (i) we know, that this addition turns the direct limit M_∞ into a commutative group again. What we have to do is check the well-definedness of the scalar multiplication: Given $a\in R$ and any $(i,x)\sim(j,y)$ we have to verify $[i,ax]=[j,ay]$. But by assumption there is some $k\geq i,\,j$ such that $\mu^k_i(x)=\mu^k_j(y)$. Multiplying this equation with a and using the R-linearity of the transition maps we find that

$$\mu^k_i(ax) = a\mu^k_i(x) = a\mu^k_j(y) = \mu^k_j(ay)$$

from which we get $(i,ax)\sim(j,ay)$. Thus the scalar multiplication also is well-defined and it remains to check the compatibility conditions (M) of an R-module. But these proves recycle the same ideas: Given $a\in R$, $[i,x]$ and $[j,y]$ we find the distributivity of the scalar multiplication from

$$\begin{aligned}a\Big([i,x]+[j,y]\Big) &= a[k,\mu^k_i(x)+\mu^k_j(y)] = [k,a(\mu^k_i(x)+\mu^k_j(y))]\\ &= [k,\mu^k_i(ax)+\mu^k_j(ay)] = [i,ax]+[j,ay] = a[i,x]+a[j,y]\end{aligned}$$

where $k\in I$ with $k\geq i,\,j$, as usual. Also $1[i,x]=[i,1x]=[i,x]$ is immediate from the construction. Likewise the associativity $(ab)[i,x]=[i,(ab)x]=[i,a(bx)]=a[i,bx]=a(b[i,x])$ for $a,\,b\in R$. And the distributivity of two scalars is straightforward to verify, as well:

$$(a+b)[i,x] = [i,(a+b)x] = [i,ax+bx] = [i,ax]+[i,bx] = a[i,x]+b[i,x]$$

(iii) By (i) above both, the addition $+$ and multiplication $\cdot$, of the direct limit R_∞ are well defined and satisfy the properties of a commutative group, resp. of a (commutative) monoid. The distributivity law in R_∞ is verified in complete analogy to the associativity of G_∞ in (i).

(iv) By (iii) above the direct limit A_∞ is a (commutative) ring under the addition and multiplication. Also A_∞ is an R-module under the scalar multiplication $a[i,f]=[i,af]$. The compatibility condition of the algebra A_∞ is straightforward again: Given $a\in R$ and $[i,f]$, $[j,g]\in A_\infty$ choose some $k\in I$

with $k \geq i, j$ and compute

$$\begin{aligned}
\Big(a[i,f]\Big)[j,g] &= [i,af][j,g] = [k,\alpha_i^k(af)\alpha_j^k(g)] = [k,a\alpha_i^k(f)\alpha_j^k(g)] \\
&= a[k,\alpha_i^k(f)\alpha_j^k(g)] = a\Big([i,f][j,g]\Big) \\
\Big(a[i,f]\Big)[j,g] &= [k,a\alpha_i^k(f)\alpha_j^k(g)] = [k,\alpha_i^k(f)\alpha_j^k(ag)] = [i,f][j,ag] = [i,f]\Big(a[j,g]\Big)
\end{aligned}$$

(v) All we have to do is verify that this construction truly yields a topology on X_∞. But $\emptyset \subseteq X_\infty$ is open, as for any $i \in I$ we have $\varepsilon_i^{-1}(\emptyset) = \emptyset \subseteq X_i$ is open and the same is true for X_∞ itself. Also the preimage ε_i^{-1} commutes with intersections and unions of sets and hence finite intersections and arbitrary unions of open sets in X_∞ are pulled back to finite intersections and arbitrary unions of open sets in X_i. And as the X_i are topological spaces these intersections resp. unions are open sets in X_i again.

□

Proof of (3.169):
In the case of topological spaces, the topology on X_∞ has been defined in exactly that manner, as to ensure that the ε_i are continuous. In the other cases we have to check the homomorphism properties: Pick up any $i \in I$ and any $x, y \in M_i$ then we compute

$$\varepsilon_i(x \cdot y) = [i, x \cdot y] = [i, \mu_i^i(x) \cdot \mu_i^i(y)] = [i,x] \cdot [i,y] = \varepsilon_i(x) \cdot \varepsilon_i(y)$$

where $\cdot$ is just any composition, not necessarily commutative. In case of R-modules and R-algebras we also have to check the R-linearity. So pick up some $a \in R$, as well, then

$$\varepsilon_i(ax) = [i, ax] = a[i,x] = a\varepsilon_i(x)$$

is even easier. So it only remains to prove: If all the maps $\mu_i^j : M_i \to M_j$ are injective, then so are the $\varepsilon_i : M_i \to M_\infty$. This is straightforward, once more: Given $x, y \in M_i$ with $\varepsilon_i(x) = \varepsilon_i(y)$ we have $[i,x] = [i,b]$ which is $\mu_i^j(x) = \mu_i^j(y)$ for some $j \geq i$. But as μ_i^j is injective, we conclude $x = y$, which is the injectivity of ε_i.

Consider topological spaces again: Suppose all of the μ_i^j are open maps, then we prove, that the ε_j are open, too. To do this we fix any $j \in I$ and an open subset $U \subseteq M_j$. We want to prove that $\varepsilon_j(U)$ is open, by definition this is the case, iff for any $i \in I$, the following set is an open subset of M_i

$$\begin{aligned}
\varepsilon_i^{-1}\Big(\varepsilon_j(U)\Big) &= \{\, x \in M_i \mid [i,x] \in \varepsilon_j(U) \,\} \\
&= \{\, x \in M_i \mid \exists\, u \in U : [i,x] \in [j,u] \,\} \\
&= \Big\{\, x \in M_i \mid \exists\, k \geq i, k\, \exists\, u \in U : \mu_i^k(x) = \mu_j^k(u) \,\Big\} \\
&= \Big\{\, x \in M_i \mid \exists\, k \geq i, k : \mu_i^k(x) \in \mu_j^k(U) \,\Big\} \\
&= \bigcup_{k \geq i,j} \Big\{\, x \in M_i \mid \mu_i^k(x) \in \mu_j^k(U) \,\Big\} \\
&= \bigcup_{k \geq i,j} (\mu_i^k)^{-1}\Big(\mu_j^k(U)\Big)
\end{aligned}$$

As by assumption all the μ_j^k are open and $U \subseteq M_j$ is open, so is $\mu_j^k(U)$. And as the μ_i^k also are continuous, we find that their preimages are open in M_i. And as any union of open sets is open, we found that $\varepsilon_i^{-1}(\varepsilon_j(U))$ is open, as needed. □

Proof of (3.170):
As (i) is a special case of (ii) it suffices to prove the latter: We already know that ε_m is a $\star$-morphism, according to (3.169). Let us verify, that the inverse map $\pi_m : [i,x] \mapsto \mu_i^m(x)$ is well-defined: Consider any $[i,x] = [j,y]$, that is $\mu_i^k(x) = \mu_j^k(y)$ for some $k \geq i, j$. By assumption we also have $m \geq k$, therefore

$$\mu_i^m(x) \;=\; \mu_k^m \mu_i^k(x) \;=\; \mu_k^m \mu_j^k(y) \;=\; \mu_j^m(y)$$

which means $[i,x]$ and $[j,y]$ are mapped to the same element of M_m under π_m. It is straightforward to check, that π_m is the inverse of ε_m: If we start with any $x \in M_m$, then $x \mapsto [m,x] \mapsto \mu_m^m(x) = x$ and if we start with some $[i,x]$ in the direct limit, then $[i,x] \mapsto \mu_i^m(x) \mapsto [m, \mu_i^m(x)] = [i,x]$. In particular ε_m is a bijective $\star$-morphism. This proves, that ε_m is an isomorphism for all the algebraic categories. For topological spaces we still have to verify, that ε_m also is an open map. If we consider any open subset $U \subseteq M_m$, then for any $i \in I$ we get (as ε_m is bijective)

$$\varepsilon_i^{-1}(\varepsilon_m(U)) \;=\; (\varepsilon_m \mu_i^m)^{-1}(\varepsilon_m(U)) \;=\; (\mu_i^m)^{-1}\varepsilon_m^{-1}(\varepsilon_m(U)) \;=\; (\mu_i^m)^{-1}(U)$$

As μ_i^m is continuous, this is an open subset of M_i and as this is true for any $i \in I$ (by defintion of the topology on the direct limit), this makes $\varepsilon_m(U)$ an open subset. Thus ε_m is open, continuous and bijective, which is a homeomorphism - an isomorphism of $\star$-objects. □

Proof of (3.171):

- The property $\iota_l^n = \iota_m^n \iota_l^m$ for any $l \leq m \leq n$ has been shown in proposition (8.15.(ii)) and hence $(R[n], \iota_m^n)$ is a direct system of commutative rings. It remains to prove the isomorphy of the direct limit $L := \varinjlim (R[n], \iota_m^n)$ to $R[\infty]$. We start by proving, that $[k,a] \mapsto \iota_k^\infty(a)$ is well-defined: That is we regard any $[k,a] = [l,b]$, that is $\iota_k^n(a) = \iota_l^n(b)$ for some $n \geq k, l$. But from this we get

 $$\iota_k^\infty(a) \;=\; \iota_n^\infty \iota_k^n(a) \;=\; \iota_n^\infty \iota_l^n(b) \;=\; \iota_l^\infty(b)$$

 It is plain to see, that this becomes a homomorphism of rings from L to $R[\infty]$. For example let us check the additivity of this map

 $$[k,a] + [l,b] \;=\; [n, \iota_k^n(a) + \iota_l^n(b)] \;\mapsto\; \iota_n^\infty\big(\iota_k^n(a) + \iota_l^n(b)\big) \;=\; \iota_k^\infty(a) + \iota_l^\infty(b)$$

- Let us define another map from $R[\infty]$ to L: Given $f \in R[\infty]$ we may invoke (8.15.(i)) to find a finite set $\Omega \subseteq I_\infty$ such that $f = \iota_\Omega^\infty(a)$ for some $a \in R[\Omega]$. As $\Omega \subseteq I_\infty$ is finite there is some $n \in \mathbb{N}$ such that $\Omega \subseteq I_n$ and hence $f = \iota_n^\infty(\check{f})$ for $\check{f} := \iota_\Omega^n(a)$. Let us define the map

 $$R[\infty] \;\to\; L \;:\; f \;\mapsto\; [n, \check{f}]$$

 where $\check{f} \in R[n]$ with $f = \iota_n^\infty(\check{f})$. We need to prove, that this is well defined: That is we suppose

$f = \iota_k^\infty(a)$ and $f = \iota_l^\infty(b)$ for some $a \in R[k]$ and $b \in R[l]$ respectively. Choose some $n \geq k, l$, then

$$\iota_n^\infty\big(\iota_k^n(a)\big) \;=\; \iota_n^\infty(f) \;=\; \iota_n^\infty\big(\iota_l^n(b)\big)$$

As ι_n^∞ is injective, we conclude $\iota_k^n(a) = \iota_l^n(b)$ and hence $[k,a] = [l,b]$, such that $f \mapsto [n,\check{f}]$ is well-defined. Let us now prove, that this map is the inverse of $[k,a] \mapsto \iota_k^\infty(a)$. Let us start with $f \in R[\infty]$, then this is mapped to

$$f \;\mapsto\; [n,\check{f}] \;\mapsto\; \iota_n^\infty(\check{f})$$

Thereby $\check{f} \in R[n]$ is chosen in such a way, that $\iota_n^\infty(\check{f}) = f$ such that f is mapped to f. Conversely, if we start with $[k,a] \in L$ then this is turned into

$$[k,a] \;\mapsto\; f := \iota_k^\infty(a) \;\mapsto\; [n,\check{f}]$$

Thereby we can chose $n = k$ and $\check{f} = a$, as $f = \iota_k^\infty(a)$ by construction. Thus $[k,a]$ is mapped to $[k,a]$ again. Altogether these maps are mutually inverse.

- Let us summarize: $[k,a] \mapsto \iota_k^\infty(a)$ is a homomorphism of rings and $f \mapsto [n,\check{f}]$ is its inverse map. That is $[k,a] \mapsto \iota_k^\infty(a)$ is bijective and hence an isomorphism.

□

Proof of (3.172):

(i) Consider any $[i,x] \in M_\infty$, that is $i \in I$ and $x \in M_i$. Then by assumption X_i generates M_i and hence there are some $a_1,\ldots,a_n \in R$ and $x_1,\ldots,x_r \in X_i$ such that $x = a_1x_1 + \cdots + a_nx_n$. And from this we see, that we can generate $[i,x]$ as an R-linear combination over X_∞:

$$[i,x] \;=\; \left[i, \sum_{r=1}^n a_r x_r\right] \;=\; \sum_{r=1}^n a_r [i,x_r] \;=\; \sum_{r=1}^n a_r \varepsilon_i(x_i)$$

(ii) Consider finitely many scalars $a_r \in R$ and elements $x_r \in X_{i(r)}$ (where $r \in 1\ldots n$ and $i(r) \in I$) such that the $[i(r),x_r] \in X_\infty$ are pairwise distinct. We have to prove, that these elements are R-linearly independent, hence we consider a relation of the form

$$0 \;=\; \sum_{r=1}^n a_r\, \varepsilon_{i(r)}(x_i) \;=\; \sum_{r=1}^n a_r [i(r),x_r] \;=\; \left[k, \sum_{r=1}^n a_r\, \mu_{i(r)}^k(x_r)\right]$$

for some $k \in I$ with $k \geq i(1),\ldots,i(n)$. The zero-element of M_∞ is given to be $0 = [j,0]$ for any $j \in I$ and $0 \in M_j$. Then we have $[j,0] = [k,z]$ if any only if $0 = \mu_j^m(0) = \mu_k^m(z)$. That is the above equation turns into

$$0 \;=\; \mu_k^m\left(\sum_{r=1}^n a_r \mu_{i(r)}^k(x_r)\right) \;=\; \sum_{r=1}^n a_r \mu_k^m \mu_{i(r)}^k(x_r) \;=\; \sum_{r=1}^n a_r \mu_{i(r)}^m(x_r)$$

Suppose we had $\mu_{i(1)}^m(x_1) = \mu_{i(2)}^m(x_2)$, then we had $[i(1),x_1] = [i(2),x_2]$ in contradiction to the $[i(r),x_r]$ being pairwise distinct. Thus the $\mu_{i(r)}^m(x_r)$ are pairwise distinct. But also $\mu_{i(r)}^m(x_r) \in$

$\mu^m_{i(r)}(X_{i(r)} \subseteq X_m$ by assumption (2). And as X_m is R-linearly independent, by assumption (1), we conclude $a_r = 0$ for any $r \in 1 \dots n$. In the end this means that the $[i(r), x_r]$ and hence X_∞ are R-linearly independent

(iii) Any R-basis X_i is R-linearly independent and hence X_∞ is R-linearly independent, according to (ii). Also any R-basis X_i generated M_i as an R-module and hence X_∞ generates M_∞ as an R-module, according to (i). Together this means X_∞ is an R-basis of M_∞ again.

□

Proof of (3.173):

(i) *Uniqueness:* First note, that for any $x = (x_i)$ and $y = (y_i) \in \mathcal{M}_\infty$ we have $x = y$ if and only if $\pi_i(x) = x_i = y_i = \pi_i(y)$ for any $i \in I$. Now suppose λ and λ' were any two maps making the diagrams $\lambda_i = \pi_i\lambda$ and $\lambda_i = \pi_i\lambda'$ commute (for any $i \in I$). Then for any $\ell \in L$ we find $\pi_i(\lambda(\ell)) = \lambda_i(\ell) = \pi_i(\lambda'(\ell))$ by the commutativity of the diagrams. And as this is true for any $i \in I$ we conclude $\lambda(\ell) = \lambda'(\ell)$. And therefore $\lambda = \lambda'$, as $\ell \in L$ has been arbitrary, too.

Existence: We have to define $\lambda : L \to M_\infty$ by $\lambda(\ell) := (\lambda_i(\ell))$. This obviously makes the diagrams $\lambda_i = \pi_i\lambda$ commute. We only have to check, that this yields a $\star$-morphism. By assumption all the μ^k_i and μ_i are $\star$-morphisms. So if $\cdot$ is any composition on $\star$-objects, then for any $i, j \in I$ and any $\ell, m \in L$ we may compute

$$\lambda(\ell \cdot m) \;=\; \Big(\lambda_i(\ell \cdot m)\Big) \;=\; \Big(\lambda_i(\ell) \cdot \lambda_i(m)\Big) \;=\; \Big(\lambda_i(\ell)\Big) \cdot \Big(\lambda_i(m)\Big) \;=\; \lambda(\ell) \cdot \lambda(m)$$

And if the $\star$-objects have a scalar multiplication over a commutative ring $(R, +, \cdot)$, then the computation is even more easy: Also consider any $a \in R$, then we find

$$\lambda(a\ell) \;=\; \Big(\lambda_i(a\ell)\Big) \;=\; \Big(a\lambda_i(\ell)\Big) \;=\; a\Big(\lambda_i(\ell)\Big) \;=\; a\lambda(\ell)$$

It remains to check the case of topological spaces, that is we need to prove, that λ is continuous. As $\mathcal{W}$ is a basis of the limit topology, it suffices to check this for any $\pi_i^{-1}(U)$ for some open subset $U \subseteq M_i$. But as λ_i is assumed to be continuous we find that the pre-image of $\pi_i^{-1}(U)$ under λ is open, from the commutativity of the diagram $\lambda_i = \pi_i\lambda$, as

$$\lambda^{-1}\Big(\pi_i^{-1}(U)\Big) \;=\; (\pi_i\lambda)^{-1}(U) \;=\; \lambda_i^{-1}(U) \;\subseteq\; L \text{ open}$$

(ii) *Uniqueness:* Suppose λ and λ' were any two maps making the diagrams $\lambda_i = \lambda\varepsilon_i$ and $\lambda_i = \lambda'\varepsilon_i$ commute (for any $i \in I$). Consider any element of M_∞, these are of the form $[i, x]$ for some $i \in I$ and $x \in M_i$. Then we already see, that $\lambda = \lambda'$ have to be equal, from

$$\lambda([i, x]) \;=\; \lambda\varepsilon_i(x) \;=\; \lambda_i(x) \;=\; \lambda'\varepsilon_i(x) \;=\; \lambda'([i, x])$$

Existence: We have to define $\lambda : M_\infty \to L$ by $\lambda([i, x]) := \lambda_i(x)$. Of course we have to check the well-definedness: If $[i, x] = [j, y]$ then there is some $k \geq i, j$ such that $\mu^k_j(x) = \mu^k_j(y)$ and hence $\lambda_i(x) = \lambda_k\mu^k_i(x) = \lambda_k\mu^k_j(y) = \lambda_j(y)$. Thus λ is constant on the the equivalence classes and hence

well-defined. It remains to verify the properties of a $\star$-morphism: By assumption all the μ_i^k and λ_i are $\star$-morphisms. So if $\cdot$ is any composition on $\star$-objects, then for any $i, j \in I$ and any $x \in M_i$, $y \in M_j$ we may compute

$$\begin{aligned}\lambda([i,x]\cdot[j,y]) &= \lambda([k,\mu_i^k(x)\cdot\mu_j^k(y)]) \;=\; \lambda_k(\mu_i^k(x)\cdot\mu_j^k(y)) \\ &= \lambda_k\mu_i^k(x)\cdot\lambda_k\mu_j^k(y) \;=\; \lambda_i(x)\cdot\lambda_j(y) \\ &= \lambda([i,x])\cdot\lambda([j,y])\end{aligned}$$

And if the $\star$-objects have a scalar multiplication over a commutative ring $(R,+,\cdot)$, then the computation is even more easy: Also consider any $a \in R$, then we find

$$\lambda(a[i,x]) \;=\; \lambda([i,ax]) \;=\; \lambda_i(ax) \;=\; a\lambda_i(x) \;=\; a\lambda([i,x])$$

It remains to check the case of topological spaces: Consider any open subset $U \subseteq L$, as λ_i is assumed to be continuous (a $\star$-morphism) $\lambda_i^{-1}(U) \subseteq M_\infty$ is open, too. But by assumption all the μ_i^j are open, such that the structure morphisms ε_i are open as well, according to (3.169). And from this we find, that λ is continuous, as we get

$$\lambda^{-1}(U) \;=\; \{\,[i,x] \in M_\infty \mid \lambda_i(x) \in U\,\} \;=\; \Big\{\,[i,x] \in M_\infty \mid x \in \lambda_i^{-1}(U)\,\Big\} \;=\; \bigcup_{i\in I} \varepsilon_i\Big(\lambda_i^{-1}(U)\Big)$$

□

Proof of (3.175):

(i) The isomorphism from $\hom(L,M_\infty)$ to H_∞ will be gained by the universal property of the inverse limit. After that it only remains to check that this $\star$-morphism is bijective.

Let us start with pointing out, that $(H_i,(\mu_j^i)_*)$ truly is an inverse system of $\star$-objects. First of all any $H_i = \hom(L,M_i)$ is a $\star$-object again. Note that R is assumed to be commutative, then this has been shown for R-modules in (3.71.(vi)) and the same arguments apply to other $\star$-objects. Also the $(\mu_j^i)_*$ are $\star$-morphisms. This has been proved for R-modules again, in (3.73.(i)). As $\mu \mapsto \mu_*$ is order preserving, the inverse system is turned into an inverse system, again.

We will now prove, that $(\hom(L,M_\infty),(\pi_i)_*)$ is a target of the inverse limit H_∞, where the $\star$-morphisms $(\pi_i)_* : \hom(L,M_\infty) \to H_i$ are defined, by $(\pi_i)_*(\psi) := \pi_i\psi$. To do this, we have to show $(\pi_i)_* = (\mu_j^i)_*((\pi_j)_*)$ for any $i \le j \in I$. So consider any $\psi \in \hom(L,M_\infty)$ and compute

$$\big((\mu_j^i)_*((\pi_j)_*)\big)(\psi) \;=\; (\mu_j^i)_*\big((\pi_j)_*(\psi)\big) \;=\; (\mu_j^i)_*(\pi_j\psi) \;=\; \mu_j^i\pi_j\psi \;=\; \pi_i\psi \;=\; (\pi_i)_*(\psi)$$

That is the requirements of the universal property (3.173.(i)) are met and hence there is a (uniquely determined) $\star$-morphism λ from $\hom(L,M_\infty)$ to H_∞, given by

$$\lambda(\psi) \;=\; \big((\pi_i)_*(\psi)\big) \;=\; \big(\pi_i\psi\big)$$

Next we prove that this λ is bijective, hence a $\star$-isomorphism: For the injectivity we regard any two ψ, $\psi' \in \hom(L,M_\infty)$, such that $\lambda(\psi) = \lambda(\psi')$. By construction of λ this is $\pi_j\psi = \pi_j\psi'$ for

any $j \in I$. Given $u \in L$ let $(x_i) := \psi(u)$ and likewise $(x'_i) := \psi'(u) \in M_\infty$. In particular

$$x_j \;=\; \pi_j((x_i)) \;=\; \pi_j\psi(u) \;=\; \pi_j\psi'(u) \;=\; \pi_j((x'_i)) \;=\; x'_j$$

for any $j \in I$. This means $\psi(u) = (x_i) = (x'_i) = \psi'(u)$ and hence $\psi = \psi'$ as $u \in L$ has been arbitrary. It remains to verify the surjectivity of λ. Note that this also establishes the explicit description of the inverse map, as given in the claim. Pick up any $(\psi_i) \in H_\infty$, note that by definition of the inverse limit this means $\psi_i = (\mu^i_j)_*(\psi_j) = \mu^i_j\psi_j$ for any $i \leq j \in I$. We need some $\psi \in \hom(L, M_\infty)$ such that $\lambda(\psi) = (\psi_i)$. That is $\pi_i\psi = \psi_i$ for any $i \in I$, by construction of λ. The obvious way to achieve this, is by taking $\psi(u) := (\psi_i(u))$ for any $u \in L$. As the ψ_i are $\star$-morphisms and the operations on M_∞ are point-wise, ψ becomes a $\star$-morphism, too. It only remains to check, that $(x_i) := \psi(u) \in M_\infty$ again. But we get this, as well, as for any $i \leq j \in I$

$$x_i \;=\; \psi_i(u) \;=\; \mu^i_j\psi_j(u) \;=\; \mu^i_j(x_j)$$

(ii) The idea is to prove, that $\hom(M_\infty, N)$ also satisfies the universal property of the inverse limit H_∞. As an universal property determines an object up to isomorphy, they have to be isomorphic. The proof will be nothing but a streamlined version of this idea: We will prove, that $\hom(M_\infty, N)$ is a target of H_∞ and present an inverse to the ensuing map λ:

Let us start with pointing out, that $(H_i, (\mu^j_i)^*)$ truly is an inverse system of $\star$-objects. First of all any $H_i = \hom(M_i, N)$ is a $\star$-object again. Note that R is assumed to be commutative, then this has been shown for R-modules in (3.71.(vi)) and the same arguments apply to other $\star$-objects. Also the $(\mu^j_i)^*$ are $\star$-morphisms. This has been proved for R-modules again, in (3.73.(ii)). As $\mu \mapsto \mu^*$ is order reversing, the direct system is turned into an inverse system.

Let us turn $\hom(M_\infty, N)$ into a target of H_∞: With the direct limit M_∞ come the structure morphisms $\varepsilon_i : M_i \to M_\infty$. These give rise to $\varepsilon^*_i : \hom(M_\infty, N) \to H_i : \psi \mapsto \psi\varepsilon_i$. And as $\varepsilon_i = \varepsilon_j\mu^j_i$ we find that the ε^*_i also satisfy requirement (3) in the universal property of the indirect limit of $(H_i, (\mu^j_i)^*)$ as for any $\psi \in \hom(M_\infty, N)$ we can compute

$$\varepsilon^*_i(\psi) \;=\; \psi\varepsilon_i \;=\; \psi\varepsilon_j\mu^j_i \;=\; (\varepsilon_j\mu^j_i)^*(\psi) \;=\; \big((\mu^j_i)^*\varepsilon^*_j\big)(\psi)$$

Thus by (3.173.(i)) there is a (uniquely defined) $\star$-morphism $\lambda : \hom(M_\infty, N) \to H_\infty$ making the diagrams $\varepsilon^*_i = \pi_i\lambda$ commute, where $\pi_i : H_\infty \to H_i$ are the canonical projections. For some $\psi \in \hom(M_\infty, N)$ this λ is given to be

$$\lambda(\psi) \;\;=\;\; \big(\varepsilon^*_i(\psi)\big) \;\;=\;\; \big(\psi\varepsilon_i\big)$$

By this we have establishes the one side of the isomorphism, to be. Let us now define its inverse, to be - we call it μ. Given $\overline{\psi} := (\psi_i) \in H_\infty$ we define

$$\mu(\overline{\psi}) \;:=\; \Big([i,x] \mapsto \psi_i(x)\Big) \;\in\; \hom(M_\infty, N)$$

Of course we first have to check the well-definedness of this map: That is (1) $\psi_i(x)$ may not depend on the choice of $[i,x]$ and $[i,x] \mapsto \psi_i(x)$ has (2) to be a $\star$-homomophism. Note that this is precisely

the map λ occurring in (3.173.(ii)), so we only have to redo the arguments there: Let us address (1) first: Suppose $[i,x] = [j,y]$ for some $i, j \in I$ and $x \in M_i$, $y \in M_j$. That is there is some $k \geq i, j$ such that $\mu_i^k(x) = \mu_j^k(y)$. And as $(\psi_i) \in H_\infty$ this means, that for any $i \leq k$ we have $\psi_i = (\mu_i^k)^*(\psi_j) = \psi_j \mu_i^j$. In particular we can compute

$$\psi_i(x) \;=\; \psi_k \mu_i^k(x) \;=\; \psi_k \mu_j^k(y) \;=\; \psi_j(y)$$

And for the same reason we get the homomorphism property (2) of $\overline{\mu} := \mu(\overline{\psi})$. Let $+$ be any composition of the $\star$-objects, then $[i,x] + [j,y]$ has been defined to be $[k, \mu_i^k(x) + \mu_j^k(y)]$, for some $k \geq i, j$ again. Thus, as $\mu_k \in H_k$ is a $\star$-morphism, we find

$$\overline{\mu}\big([i,x] + [i,y]\big) \;=\; \psi_k\big(\mu_i^k(x) + \mu_j^k(y)\big) \;=\; \psi_k \mu_i^k(x) + \psi_k \mu_j^k(y) \;=\; \psi_i(x) + \psi_j(y)$$

which is $\overline{\mu}([i,x]) + \overline{\mu}([j,y])$ again. If needed, the R-linearity is even easier again: By scalar multiplication on M_∞ we simply have $\overline{\mu}(a[i,x]) = \overline{\mu}([i,ax]) = \psi_i(ax) = a\psi_i(x) = a\overline{\mu}([i,x])$.

It remains to prove, that these maps λ and μ are mutually inverse: Let us start with $\overline{\psi} = (\mu_i) \in H_\infty$, then we have to show $\lambda\mu(\overline{\psi}) = \overline{\psi}$. Let $\psi := \mu(\overline{\psi})$, then $\lambda\mu(\overline{\psi}) = \lambda(\psi) = (\psi\varepsilon_i)$. That is we have to show $\psi\varepsilon_i = \psi_i \in H_i$ for any $i \in I$. But this is clear, as for any $x \in M_i$ we have $\psi\varepsilon_i(x) = \psi([i,x]) = \mu(\overline{\psi})([i,x]) = \psi_i(x)$. And as this is true for any $x \in M_i$ we have $\psi\varepsilon_i = \psi_i$ and thereby $\lambda\mu$ is the identity on H_∞, as needed.

For the converse direction we start with some $\psi \in \hom(M_\infty, N)$ and have to prove $\mu\lambda(\psi) = \psi$. Let $\psi_i := \psi\varepsilon_i \in H_i$, that is $\overline{\psi} := \lambda(\psi) = (\psi_i)$. Now take a look at $\mu(\overline{\psi})$, by construction this maps $[i,x] \mapsto \psi_i(x) = \psi\varepsilon_i(x) = \psi([i,x])$. Thus $\mu(\overline{\psi})$ and ψ map any $[i,x]$ to the same element and hence are equal $\psi = \mu(\overline{\psi}) = \mu\lambda(\psi)$. That is $\mu\lambda$ also is the identity, as needed. In the end λ is a bijective $\star$-morphism with inverse map μ and thereby a $\star$-isomorphism.

□

Proof of (3.177):

(i) Let us first check the well-definedness of φ_∞: If we start with some $(x_i) \in M_\infty$ we have to check that $(y_i) := (\varphi_i(x_i)) \in N_\infty$ again. To do this regard any $i \leq j \in I$, then we have $\mu_j^i(x_j) = x_i$ and thereby can compute

$$\nu_j^i(y_j) \;=\; \nu_j^i \varphi_j(x_j) \;=\; \varphi_i \mu_j^i(x_j) \;=\; \varphi_i(x_i) \;=\; y_i$$

For inverse systems of algebraic $\star$-object, the compositions are point-wise. And as all the φ_i are $\star$-morphisms, φ_∞ respects these compositions. Thus for algebraic $\star$-objects, φ_∞ clearly is a $\star$-morphism, again. It remains to check the case of topological spaces: Hereby $(I, \leq)$ has to be a net. We have to verify, that φ_∞ is continuous, again. To do this, it suffices to regard open base sets of the topology, that is sets of the form $\pi_j^{-1}(V_j)$ for some open set $V_j \subseteq N_j$. But an easy computation shows, that the preimages of such sets, are open in M_∞ again

$$\varphi_\infty^{-1}\big(\pi_j^{-1}(V_j)\big) \;=\; \varphi_\infty^{-1}\Big(\big\{ (y_i) \in N_\infty \mid y_j \in V_j \big\} \Big)$$

$$
\begin{aligned}
&= \left\{ (x_i) \in M_\infty \mid \varphi_j(x_j) \in V_j \right\} \\
&= \left\{ (x_i) \in M_\infty \mid x_j \in \varphi_j^{-1}(V_j) \right\} \\
&= \pi_j^{-1}\big(\varphi_j^{-1}(V_j)\big)
\end{aligned}
$$

(ii) We first have to check the well-definedness of φ_∞ again: Consider any $[i,u]$, $[j,x] \in M_\infty$, then we have to verify $[i,\varphi_i(u)] = [j,\varphi_j(x)]$. By assumption there is some $k \geq i, j$ such that $\mu_i^k(u) = \mu_j^k(x)$. If we apply φ_k to this identity, we get $\nu_i^k\varphi_i(u) = \varphi_k\mu_i^k(u) = \varphi_k\mu_j^k(x) = \nu_j^k\varphi_j(x)$ which means $[i,\varphi_i(u)] = [j,\varphi_j(x)]$, as needed. For algebraic $\star$-objects the commutativity (2) of the diagrams also is the reason for the homomorphism property of φ_∞: Consider any two $[i,u]$ and $[j,x] \in M_\infty$ and let $\cdot$ be the composition of the $\star$-objects. If $k \geq i, j$, then we find

$$
\begin{aligned}
\varphi_\infty\big([i,u]\cdot[j,x]\big) &= \varphi_\infty\big([k,\mu_i^k(u)\cdot\mu_j^k(x)]\big) \\
&= [k,\varphi_k(\mu_i^k(u)\cdot\mu_j^k(x))] \\
&= [k,\varphi_k\mu_i^k(u)\cdot\varphi_k\mu_j^k(x)] \\
&= [k,\nu_i^k\varphi_i(u)\cdot\mu_j^k\varphi_j(x)] \\
&= [i,\varphi_i(u)]\cdot[j,\varphi_j(x)] \\
&= \varphi_\infty\big([i,u]\big)\cdot\varphi_\infty\big([j,x]\big)
\end{aligned}
$$

As always, if the $\star$-objects have a scalar multiplication, the linearity is even easier to see: $\varphi_\infty(a[i,u]) = \varphi_\infty([i,au]) = \varphi_i(au) = a\varphi_i(u) = a\varphi_\infty([i,u])$. It remains to treat topological spaces, where we assume the ν_i^j to be open, again. To prove, that φ_∞ is continuous we pick up an open subset $V \subseteq N_\infty$ and have to prove, that $\varphi_\infty^{-1}(V) \subseteq M_\infty$ is open again. That is we have to regard the pre-images $\varepsilon_i^{-1}(\varphi_\infty^{-1}(V))$. Choose any $i \in I$ and $x \in M_i$ then

$$
\begin{aligned}
x \in \varepsilon_i^{-1}(\varphi_\infty^{-1}(V)) &\iff [i,x] \in \varphi_\infty^{-1}(V) \\
&\iff [i,\varphi_i(x)] \in V \\
&\iff \exists\, [j,y] \in V \,:\, [i,\varphi_i(x)] = [j,y] \\
&\iff \exists\, [j,y] \in V\ \exists\, k \geq i,j \,:\, \nu_i^k\varphi_i(x) = \nu_j^k(y) \\
&\iff \exists\, [j,y] \in V\ \exists\, k \geq i,j \,:\, \varphi_k\mu_j^k(x) = \nu_j^k(y) \\
&\iff \exists\, \varepsilon_j(y) \in V\ \exists\, k \geq i,j \,:\, x \in (\mu_j^k)^{-1}\varphi_k^{-1}\nu_j^k(y) \\
&\iff \exists\, y \in \varepsilon_j^{-1}(V)\ \exists\, k \geq i,j \,:\, x \in (\mu_j^k)^{-1}\varphi_k^{-1}\nu_j^k(y) \\
&\iff \exists\, j \in I\ \exists\, k \geq i,j \,:\, x \in (\mu_j^k)^{-1}\varphi_k^{-1}\nu_j^k\varepsilon_j^{-1}(V)
\end{aligned}
$$

As $V \subseteq N_\infty$ is open, $\varepsilon_j^{-1}(V) \subseteq N_j$ is open by definition of the topology. As ν_j^k is open, φ_k and μ_j^k are continuous, this means, that $\varepsilon_i^{-1}(\varphi_\infty^{-1}(V))$ - and thereby $\varphi_\infty^{-1}(V)$ - is open, as we have seen

$$
\varepsilon_i^{-1}(\varphi_\infty^{-1}(V)) = \bigcup_{j\in I}\bigcup_{k\geq i,j} (\mu_j^k)^{-1}\varphi_k^{-1}\nu_j^k\varepsilon_j^{-1}(V)
$$

□

Proof of (3.178):

(i) It is quite easy to see, that φ_∞ is injective again: To say that $(x_i) \in \mathrm{kn}(\varphi_\infty)$ means $\varphi_i(x_i) = 0$ for any $i \in I$. But as all the φ_i are injective, we conclude $x_i = 0$ which is $(x_i) = 0$ and hence the injectivity of φ_∞. It only remains to verify $\mathrm{im}(\varphi_\infty) = \mathrm{kn}(\psi_\infty)$. By assumption all i-th chains are exact and hence $\mathrm{im}(\varphi_i) = \mathrm{kn}(\psi_i)$. Thus $\psi_i(y_i) = 0$ (for some $y_i \in M_i$) means there is some $x_i \in L_i$ such that $y_i = \varphi_i(x_i)$. Using this equivalence we find

$$\begin{aligned} \mathrm{im}(\varphi_\infty) &= \{\, (\varphi_i(x_i)) \in M_\infty \mid (x_i) \in L_\infty \,\} \\ \mathrm{kn}(\psi_\infty) &= \{\, (y_i) \in M_\infty \mid \forall\, i \in I\ \exists\, x_i \in L_i \,:\, y_i = \varphi_i(x_i) \,\} \end{aligned}$$

The inclusion $\mathrm{im}(\varphi_\infty) \subseteq \mathrm{kn}(\psi_\infty)$ is obvious: Given $(y_i) := (\varphi_i(x_i))$ for any $i \in I$ there is some $x_i \in L_i$ such that $y_i = \varphi_i(x_i)$. Conversely for $\mathrm{im}(\varphi_\infty) \supseteq \mathrm{kn}(\psi_\infty)$ consider any $i \leq j \in I$. As $(y_i) \in M_\infty$ we have $\mu_j^i(y_j) = y_i$. Pick up any $x_i \in L_i$ such that $y_i = \varphi_i(x_i)$, then this turns into $\mu_j^i \varphi_j(x_j) = \varphi_i(x_i)$. But as (φ_i) is a homomorphism of R-module-systems this is $\varphi_i \lambda_j^i(x_j) = \varphi_i(x_i)$. Recall that φ_i is injective, by this we conclude $\lambda_j^i(x_j) = x_i$. And as this is true for all $i \leq j$ we find $(x_i) \in L_\infty$ and hence $(y_i) \in \mathrm{im}(\varphi_\infty)$.

(ii) Let us start with the injectivity of φ_∞: Consider any $[i,x] \in L_\infty$ such that $0 = \varphi_\infty([i,x]) = [i, \varphi_i(x)]$. Choose any $j \in I$, then $[j,0] = 0$ such that we have $[i,\varphi_i(x)] = [j,0]$ which means $\mu_i^k \varphi_i(x) = \mu_j^k(0) = 0$ for some $k \geq i, j$. As (φ_i) is a homomorphism of the direct systems, we get $\varphi_k \lambda_i^k(x) = 0$. But by assumption φ_k is injective and thereby $\lambda_i^k(x) = 0 = \lambda_j^k(0)$. From this we get $[i,x] = [j,0] = 0$ which is the injectivity of φ_∞.

The surjectivity of ψ_∞ is really easy: Pick up any $[i,z] \in N_\infty$ that is $i \in I$ and $z \in N_i$. As ψ_i is surjective, there is some $y \in M_i$ such that $\psi_i(y) = z$. From this we get $[i,z] = [i,\psi_i(y)]$ and this is $[i,z] = \psi_\infty([i,y])$. In particular ψ_∞ is surjective.

It only remains to prove $\mathrm{im}(\varphi_\infty) = \mathrm{kn}(\psi_\infty)$. So let us decode the content, of these sets. By construction, we have

$$\begin{aligned} \mathrm{im}(\varphi_\infty) &= \{\, [i,\varphi_i(x)] \in M_\infty \mid i \in I,\, x \in L_i \,\} \\ \mathrm{kn}(\psi_\infty) &= \{\, [i,y] \in M_\infty \mid [i,\psi_i(y)] = 0 \,\} \end{aligned}$$

Hence the inclusion $\mathrm{im}(\varphi_\infty) \subseteq \mathrm{kn}(\psi_\infty)$ is easy to see: As $\psi_i \varphi_i(x) = 0$ for any $i \in I$ and any $x \in L_i$ we find that $[i,y] = [i,\varphi_i(x)]$ satisfies $[i,\psi_i(y)] = [i,\psi_i\varphi_i(x)] = [i,0] = 0$. For the converse inclusion, we start with some $[i,y]$ such that $[i,\psi_i(y)] = 0$. Again $0 = [j,0]$ for an arbitrary $j \in I$. From $[i,\psi_i(y)] = [j,0]$ we find some $k \geq i, j$ such that $\nu_i^k \psi_i(y) = \nu_j^k(0) = 0$. As (ψ_i) is a homomorphism of R-module-systems, this can be turned into $\psi_k \mu_i^k(y) = 0$, which is $\mu_i^k(y) \in \mathrm{kn}(\psi_k) = \mathrm{im}(\varphi_k)$. That is there is some $x_k \in L_k$ such that $\mu_i^k(y) = \varphi_k(x) = \mu_k^k \varphi_k(x)$. So we see $[i,y] = [k,\varphi_k(x)] \in \mathrm{im}(\varphi_\infty)$, the converse inclusiom.

□

Proof of (7.46):

- (a) $\Longrightarrow$ (b): consider any element $f \in \mathfrak{h}$ and pick up the homogeneous decomposition $f = \sum_d f_d$. By assumption (a) and as $f \in \mathfrak{h}$ we also find $h_d \in \mathfrak{h} \cap A_d$ such that f can be decomposed into $f = \sum_d h_d$. As f_d and $h_d \in A_d$ property (3) of graded algebras implies $f_d = h_d \in \mathfrak{h}$.

- (b) $\implies$ (c): For any $h \in \mathfrak{h}$ let us consider the homogeneous decomposition $h = \sum_d h_d$ and denote the set $H := \{\, h_d \mid h \in \mathfrak{h},\ h_d \neq 0 \,\}$. Then it is clear that $H \subseteq A_{\text{hom}}$, by definition of H. And by assumption (b) we have $H \subseteq \mathfrak{h}$. On the other hand any $h \in \mathfrak{h}$ has been decomposed as $h = \sum_d h_d \in \langle H \rangle_{\mathfrak{i}}$. And hence $\mathfrak{h} \subseteq \langle H \rangle_{\mathfrak{i}} \subseteq \mathfrak{h}$.

- (c) $\implies$ (a): Consider any $f \in \mathfrak{h} = \langle H \rangle_{\mathfrak{i}}$, that is there is a finite subset $\Omega \subseteq H$ and elements $g_h \in A$ (where $h \in \Omega$) such that $f = \sum_h g_h h$. For any $h \in \Omega$ let us abbreviate $d(h) := \deg(h)$ and pick up homogeneous decompositions $f = \sum_d f_d$ and $g_h = \sum_d g_{h,d}$. Then we compute

$$\sum_{d \in D} f_d \;=\; f \;=\; \sum_{h \in \Omega} \left(\sum_{d \in D} g_{h,d} \right) h \;=\; \sum_{d \in D} \sum_{h \in \Omega} g_{h,d} h$$

 As $g_{h,d}$ and h are homogeneous elements $g_{h,d}h$ is (either 0 or) a homogeneous element of degree $\deg(g_{h,d}h) = \deg(g_{h,d}) + \deg(h) = d + d(h)$. Thus we can split the sum over $(d,h) \in D \times \Omega$ into fibers (c,h) such that $c + d(h) = d$. Thereby we find

$$\sum_{d \in D} f_d \;=\; \sum_{d \in D} \sum_{c + d(h) = d} g_{h,c} h$$

 So on both sides of this equation we have homogeneous decompositions of f. Now by property (3) of graded algebrad this means that (for any $d \in D$) the homogeneous components have to coincide, too. That is

$$f_d \;=\; \sum_{c + d(h) = d} g_{h,c} h \;\in\; \mathfrak{h} \cap A_d$$

 Hence we have obtained that f can be decomposed as a sum of elements f_d contained in $\mathfrak{h} \cap A_d$. As f has been arbitrary that is $\mathfrak{h} = \sum_d \mathfrak{h} \cap A_d$. And as $\mathfrak{h} \cap A_d \subseteq A_d$ it is also clear that $(\mathfrak{h} \cap A_d) \cap (\sum_{c \neq d} \mathfrak{h} \cap A_c) \subseteq A_d \cap (\sum_{c \neq d} A_c) = 0$. Altogether we have obtained claim (a).

□

Proof of (7.40):
If f_k is homogeneous of degree $m - k$ then $f_k t_n^k$ is homogeneous of degree $(m-k)+k = m$. And as all these polynomials have the same degree m, the sum is homogeneous again. As $d = \deg_n(f)$ we have $f_d \neq 0$, Such that we have already established (b) $\implies$ (a). Conversely, as f is of degree $m = \deg(f)$, then the only multi-indices $\beta \in \mathbb{N}^n$ with $f[\beta] \neq 0$ satisfy $|\beta| \leq m$. If f also is homogeneous, then they even satisfy $|\beta| = m$. Therefore f is of the form

$$f \;=\; \sum_{|\beta| = m} f[\beta]\, t^\beta$$

Let us split $\beta \in \mathbb{N}^n$ up into $\beta = (\alpha, k)$, that is $k := \beta_n$ and $\alpha := (\alpha_1, \ldots, \alpha_{n-1})$. Then $|\alpha| = |\beta| - k = m - k$ such that we are able to rewrite f as

$$f \;=\; \sum_{k=0}^{d} \left(\sum_{|\alpha| = r-k} f[\alpha, k]\, t^\alpha \right) t^k$$

Here the polynomials in brackets are $f_k \in R[t_1, \ldots, t_{n-1}]$. As f was homogeneous we had $|\beta| = m$ which led to $|\alpha| = m - k$. Thus $f_k = 0$ or homogeneous of degree $m - k$. Note that $f_d \neq 0$, as f had a

coefficient $f[\beta] \neq 0$ for some $\beta = (\alpha, d)$. For a general polynomial we had $|\beta| \leq m$ instead and hence only $|\alpha| \leq m - k$ which yields $\deg(f_k) \leq m - k$ instead. □

Proof of (7.48):

(i) Let us write out the homogeneous decomposition $1 = \sum_d 1_d$. Then for any homogeneous element $h \in H$ - say $c := \deg(h)$ - we get

$$h \;=\; h \cdot 1 \;=\; \sum_{d \in D} h \cdot 1_d$$

Thereby $h \cdot 1_d \in A_{c+d}$ according to property (4). But as $h \in H$ is homogeneous we may compare coefficients (this is property (3)) to find $h = \sum_{c+d=c} h \cdot 1_d$. Yet D has been assumed to be integral, hence $c + d = c = c + 0$ implies $d = 0$. Thus for any $h \in H$ we have found $h = h \cdot 1_0$. Thus consider any $f \in A$ and decompose $f = \sum_d f_d$ into homogeneous elements. Then we compute

$$f \cdot 1_0 \;=\; \sum_{d \in D} f_d \cdot 1_0 \;=\; \sum_{d \in D} f_d \;=\; 0$$

as the $f_d \in H \cup \{0\}$ are homogeneous. Thus we have proved $f = f \cdot 1_0$ for *any* element $f \in A$. In particular $1 = 1 \cdot 1_0 = 1_0 \in A_0$.

(ii) Clearly the kernel is an ideal $\mathfrak{a} := \ker(\varphi) \trianglelefteq_{\mathrm{i}} A$ of A, so we only have to prove the graded property. First of all, it is clear that the sub-modules $\mathfrak{a} \cap A_d$ intersect trivially

$$(\mathfrak{a} \cap A_c) \cap \left(\sum_{d \neq c} \mathfrak{a} \cap A_d \right) \quad \subseteq \quad A_c \cap \left(\sum_{d \neq c} A_d \right) \quad = \quad \{0\}$$

Thus it remains to show that $\mathfrak{a}$ truly is the sum of the $\mathfrak{a} \cap A_d$. Consider any $f \in \mathfrak{a}$ and decompose f into homogeneous components $f = \sum_d f_d$ where $f_d \in A_d$. Then we get

$$0 \quad = \quad \varphi(f) \quad = \quad \sum_{d \in D} \varphi(f_d)$$

As φ was assumed to be graded, we have $\varphi(f_d) \in B_d$ again. Thus comparing homogeneous coefficients in B we find $\varphi(f_d) = 0$ for any $d \in D$. And this again translated into $f_d \in \mathfrak{a}$ such that $f_d \in \mathfrak{a} \cap A_d$. As f has been arbitrary this also shows

$$\mathfrak{a} \;=\; \sum_{d \in D} \mathfrak{a} \cap A_d$$

(iii) As $\mathfrak{a} \trianglelefteq_{\mathrm{i}} A$ is an ideal and A is an R-algebra, $\mathfrak{a} \trianglelefteq_{\mathrm{a}} A$ even is an R-algebra-ideal. And hence the quotient $A/\mathfrak{a}$ is an R-algebra again. And by construction we have $0 + \mathfrak{a} \notin (A/\mathfrak{a})_{\mathsf{hom}}$. Let us now prove the well-definedness of $\deg : (A/\mathfrak{a})_{\mathsf{hom}} \to D$: suppose we are given g and $h \in A$ such that $g + \mathfrak{a} = h + \mathfrak{a} \in (A/\mathfrak{a})_{\mathsf{hom}}$. That is $f := g - h \in \mathfrak{a}$. Let us now denote $b := \deg(g)$ and $c := \deg(h)$ and decompose $f = \sum_d f_d$ (where $f_d \in \mathfrak{a} \cap A_d$ by assumption). Then we find

$$\sum_{d \in D} \begin{cases} g \text{ if } d = b \\ 0 \text{ if } d \neq b \end{cases} \;=\; g \;\; f + h \;\; = \;\; \sum_{d \in D} \begin{cases} f_c + h \text{ if } d = c \\ f_d \text{ if } d \neq c \end{cases}$$

Now suppose we had $b \neq c$ then comparing coefficients we would find $g = f_b \in \mathfrak{a}$ in contradiction to $g + \mathfrak{a} \in (A/\mathfrak{a})_{\text{hom}}$. Thus we have $\deg(g) = b = c = \deg(h)$ and hence $\deg : (A/\mathfrak{a})_{\text{hom}} \to D$ is well-defined. We will now prove the identity

$$\left(A \Big/ \mathfrak{a}\right)_d \;=\; A_d + \mathfrak{a} \Big/ \mathfrak{a}$$

For the inclusion "$\subseteq$" we are given some $h + \mathfrak{a} \in (A/\mathfrak{a})_d$. If thereby $h + \mathfrak{a} = 0 + \mathfrak{a}$ then $h \in \mathfrak{a}$ and hence $h + \mathfrak{a} \in (A_d + \mathfrak{a})/\mathfrak{a}$. If on the other hand $h + \mathfrak{a} \neq 0 + \mathfrak{a}$ then we have $\deg(h) = d$ by assumption and hence $h \in A_d$. Altogether $h + \mathfrak{a} \in (A_d + \mathfrak{a})/\mathfrak{a}$ again. Conversely "$\supseteq$" consider any $h \in A_d$ and any $f \in \mathfrak{a}$. Then we have to show $(h + f) + \mathfrak{a} \in (A/\mathfrak{a})_d$. If $h = 0$ then $(h + f) + \mathfrak{a} = 0 + \mathfrak{a} \in (A/\mathfrak{a})_d$ is clear. And if $h \neq 0$ then $\deg(h) = d$ by assumption such that $(h + f) + \mathfrak{a} = h + \mathfrak{a}$ is of degree d, as well. Thus we have established the equality and in particular $(A/\mathfrak{a})_d$ is an R-sub-module of $A/\mathfrak{a}$. Now consider $g \in A_c$, $h \in A_d$ and a, $b \in \mathfrak{a}$. Then $(g + a)(h + b) = gh + (ah + gb + ab) \in A_{c+d} + \mathfrak{a}$. And as all these elements have been arbitrary this also proves property (4) of graded algebras, that is $(A/\mathfrak{a})_c (A/\mathfrak{a})_d \subseteq (A/\mathfrak{a})_{c+d}$. Now

$$A \Big/ \mathfrak{a} \;=\; \sum_{d \in D} A_d + \mathfrak{a} \Big/ \mathfrak{a}$$

is easy to see: if we are given any $f + \mathfrak{a} \in A/\mathfrak{a}$ then we may decompose $f = \sum_d f_d$ into homogeneous components. Thereby $f + \mathfrak{a} = \sum_d (f_d + \mathfrak{a})$. This already yields "$\subseteq$" and the converse inclusion is clear. Now fix any $c \in D$ then it remains to prove

$$\left(A_c + \mathfrak{a} \Big/ \mathfrak{a}\right) \cap \left(\sum_{d \neq c} A_d + \mathfrak{a} \Big/ \mathfrak{a}\right) \;=\; \{\, 0 + \mathfrak{a} \,\}$$

Thus consider any $f + \mathfrak{a}$ contained in the intersection. In particular that is $f + \mathfrak{a} \in (A_c + \mathfrak{a})/\mathfrak{a}$ and hence there is some $f_c \in A_c$ such that $f + \mathfrak{a} = f_c + \mathfrak{a}$. And likewise there are $f_d \in A_d$ (where $d \neq c$) such that $f + \mathfrak{a} = \sum_{d \neq c} f_d + \mathfrak{a}$. Thus we find

$$a \;:=\; f_c - \sum_{d \neq c} f_d \;\in\; \mathfrak{a} \;=\; \bigoplus_{d \in D} \mathfrak{a} \cap A_d$$

as $\mathfrak{a}$ has been assumed to be a graded ideal we can decompose a into $a = \sum_d a_d$ where $a_d \in \mathfrak{a} \cap A_d$. Comparing the homogeneous coefficients of a in A we find $f_c = a_c \in \mathfrak{a} \cap A_c$. In particular $f + \mathfrak{a} = f_c + \mathfrak{a} = 0 + \mathfrak{a}$, which had to be shown.

(iv) As U is multiplicatively closed $U^{-1}A$ is a commutative R-algebra under $a(f/u) = (af/u)$. And from the construction of $(U^{-1}A)_{\text{hom}}$ we also have $0 = 0/1 \notin (U^{-1}A)_{\text{hom}}$. As D was assumed to be a group $\deg : (U^{-1}A)_{\text{hom}} \to D$ is a well-defined map. (If D only was a monoid we would have to regard $\deg : (U^{-1}A)_{\text{hom}} \to \text{gr}D$ given by $\deg(h/u) := (\deg(h), \deg(u))$ instead). Next we prove

$$\left(U^{-1}A\right)_d \;=\; \left\{ \frac{h}{u} \;\middle|\; u \in U,\, h \in A_{d + \deg(u)} \right\}$$

The inclusion "$\supseteq$" is easy: the case $h/u = 0/1$ is clear and if $h/u \neq 0/1$ we particularly have $h \neq 0$. Hence $\deg(h) = \deg(u) + d$ by assumption on h and hence $\deg(h/u) = \deg(h) - \deg(u) = d$.

The converse "$\subseteq$" is analogous: the case $h/u = 0/1$ is clear again, as $0 \in A_{d+\deg(u)}$. And if $h/u \neq 0/1$ then $d = \deg(h/u) = \deg(h) - \deg(u)$ and hence $h \in A_{d+\deg(u)}$ again. So we have to verify that $(U^{-1}A)_d$ is an R-sub-module. Suppose $a \in R$ and g/u, $h/v \in (U^{-1}A)_d$. Then $ag \in A_{d+\deg(u)}$ and hence $a(g/u) \in (U^{-1}A)_d$ again. Furthermore

$$\frac{g}{u} + \frac{h}{v} \;=\; \frac{gv + hu}{uv}$$

As $\deg(uv) = \deg(u) + \deg(v)$ we have gv and $hu \in A_{d+\deg(uv)}$ thus $gv + hv \in A_{d+\deg(uv)}$ again and this means $(gv + hu)/uv \in (U^{-1}A)_d$. So let us now verify property (4) of graded algebras. To do this consider $g/u \in (U^{-1}A)_c$ and $h/v \in (U^{-1}A)_d$. Then we have to verify $(gh)/(uv) = (g/u)(h/v) \in (U^{-1}A)_{c+d}$. If $(gh)/(uv) = 0$ we are done, else we have $\deg(g) = c + \deg(u)$ and $\deg(h) = d + \deg(v)$. Thus $\deg(gh) = \deg(g) + \deg(h) = c + \deg(u) + d + \deg(v) = (c+d) + \deg(uv)$. And this already is $(gh/(uv) \in (U^{-1}A)_{c+d}$. It remains to verify property (3) of graded algebras. Given any $f/u \in U^{-1}A$ let us pick up a homogeneous decomposition $f = \sum_d f_d$ of f in A. Then $f/u = \sum_d f_d/u$ and as $f_d/u \in (U^{-1}A)_{d-\deg(u)}$ and as f has been arbitrary this means $U^{-1}A = \sum_d (U^{-1}A)_d$. Thus it only remains to prove

$$\Big(U^{-1}A\Big)_d \cap \left(\sum_{c \neq d} \Big(U^{-1}A\Big)_c\right) \;=\; 0$$

Thus consider some h/v contained in the intersection. We have to prove $h/v = 0/1$ thus let us suppose $h/v \neq 0/1$ and deduce a contradiction. As $h/v \in (U^{-1}A)_d$ that is $h \in A_{d+\deg(v)}$. And likewise there is some finite subset $\Omega \subseteq D \setminus \{c\}$ and $u_c \in U$, $g_c \in A_{c+\deg(u_c)}$ (where $c \in \Omega$) such that $h/v = \sum_c g_c/u_c$. Now let $u := \prod_c u_c \in U$ and $\widehat{u}_c := u/u_c \in U$ then we compute

$$\frac{h}{v} \;=\; \sum c \in \Omega \frac{g_c}{u_c} \;=\; \frac{1}{u}\left(\sum_{c\in\Omega} g_c \widehat{u}_c\right)$$

That is there is some $w \in U$ such that $uwh = vw\sum_c g_c\widehat{u}_c$. Note that uwh and the $vwg_c\widehat{u}_c$ are homogeneous elements of A, where

$$\begin{aligned}
\deg(vwg_c\widehat{u}_c) &= \deg(v) + \deg(w) + c + \deg(u_c) + \sum_{b\neq c} \deg(u_b) \\
&= \deg(v) + \deg(w) + c + \sum_{c\in\Omega} \deg(u_c) \\
&= \deg(uvw) + c
\end{aligned}$$

Hence all the $vwg_c\widehat{u}_c$ have different degrees and hence form a homogeneous decomposition of uwh. This however is homogeneous too, of degree $\deg(uwh) = \deg(uw) + d + \deg(v) = \deg(uvw) + d$. As $c \neq d$ this is yet another homogeneous decomposition. Hence $uwh = 0$ which would mean $h/v = 0/1$, a contradiction.

(v) Consider any $f \in \sqrt{\mathfrak{a}}$ that is $f^k \in \mathfrak{a}$ for some $k \in \mathbb{N}$. If $k = 0$ then $1 \in \mathfrak{a}$ and hence $\mathfrak{a} = A$. This would imply $\sqrt{\mathfrak{a}} = A$, too, which clearly is a graded ideal again. Thus let us consider the case $k \geq 1$. Pick up the hoomogeneous decomposition $f = \sum_d f_d$ of f, then by (7.46) it suffices to check

$f_d \in \sqrt{\mathfrak{a}}$ for any $d \in \mathbb{N}$. Now compute

$$f^k \;=\; \sum_{\alpha\in\mathbb{N}^k} f_{\alpha_1}\dots f_{\alpha_k} \;=\; \sum_{d\in\mathbb{N}}\sum_{|\alpha|=d} f_{\alpha_1}\dots f_{\alpha_k} \;\in\; \mathfrak{a}$$

where $|\alpha| := \alpha_1 + \dots + \alpha_k \in \mathbb{N}$. By definition of graded algebras it is clear that $f_{\alpha_1}\dots f_{\alpha_k} \in A_{|\alpha|}$ and thus we have found the homogeneous decomposition of f^k. As $\mathfrak{a}$ is a graded ideal, this implies

$$\forall\, d \in \mathbb{N} \;:\; \sum_{|\alpha|=d} f_{\alpha_1}\dots f_{\alpha_k} \;\in\; \mathfrak{a}$$

We will now prove that $f_d \in \sqrt{\mathfrak{a}}$ by induction on d. For $d = 0$ we have $\{\, |\alpha| = 0 \,\} = \{0\}$ and hence $f_0^k = \sum_{|\alpha|=0} f_{\alpha_1}\dots f_{\alpha_k} \in \mathfrak{a}$. Thus suppose $d \geq 1$, then we define the following function

$$\mu \;:\; \{\, |\alpha| = kd \,\} \to \mathbb{N} \;:\; \alpha \mapsto \min\{\, \alpha_i \mid i \in 1\dots k \,\}$$

It is clear that $\mu(\alpha) \leq d$ (as else $|\alpha| \geq k(d+1) > kd$) and that $\mu(\alpha) = d$ is equivalent to $\alpha = (d,\dots,d)$ (as else $|\alpha| > kd$). Hence we get

$$\begin{aligned} f_d^k &= \sum_{\mu(\alpha)=d} f_{\alpha_1}\dots f_{\alpha_k} \\ &= \sum_{|\alpha|=kd} f_{\alpha_1}\dots f_{\alpha_k} - \sum_{\mu(\alpha)<d} f_{\alpha_1}\dots f_{\alpha_k} \end{aligned}$$

But we have already seen from the gradedness of $\mathfrak{a}$ that the first term (the sum over $|\alpha| = kd$) is contained in $\mathfrak{a}$ again. And if $\mu(\alpha) < d$ then the induction hypothesis yields $f_{\mu(\alpha)} \in \sqrt{\mathfrak{a}}$. Yet it is clear that $f_{\mu(\alpha)} \mid f_{\alpha_1}\dots f_{\alpha_k}$ and hence $f_{\alpha_1}\dots f_{\alpha_k} \in \sqrt{\mathfrak{a}}$ again. Thus the second term (the sum over $\mu(\alpha) < d$) is contained in $\sqrt{\mathfrak{a}}$, too. And this implies $f_d^k \in \sqrt{\mathfrak{a}}$ and hence even $f_d \in \sqrt{\mathfrak{a}}$, which had to be shown.

□

Proof of (7.42):
The only statements that is not covered in (6.41) is the fact that the multiplication $R^2 \to R : (a,b) \mapsto ab$ is continuous, as well. And for this we also have to prove the explicit reformulation in terms of the box topology, given in the note. By definition the multiplication is continuous, iff for any open set $W \subseteq R$ the preimage $P := \{\, (a,b) \in R^2 \mid ab \in W \,\}$ is an open set in R^2. But by definition of the box topology P is open, iff for any $(a,b) \in P$ there are open subsets $U \in \mathcal{O}(a)$ and $V \in \mathcal{O}(b)$ such that $U \times V \subseteq P$. The latter means $uv \in W$ for any $u \in U$ and $v \in V$ and likewise $(a,b) \in P$ translates into $ab \in W$.
That is, we have to verify: For any a, $b \in R$ with $ab \in W$ there are some $U \in \mathcal{O}(a)$ and $V \in \mathcal{O}(b)$ such that for any $u \in U$ and any $v \in V$ we have $uv \in W$ again. So we start with a, $b \in R$ such that $ab \in W$ and have to find these open neighbourhoods U and V. As $W \subseteq R$ is open, there is some $n \in \mathbb{N}$ such that $ab + \mathfrak{a}^n \subseteq W$. We then choose $U := B_r(a)$ and $V := B_r(b)$ for $r := 2^{-n}$. That is $u \in U$ means $d(a,u) < r$ which turns into $\operatorname{ord}(u-a) > n$. In particular $\alpha := u - a \in \mathfrak{a}^n$ (even in $\mathfrak{a}^{n+1}$, but we do not need this). Likewise $\beta := v - b \in \mathfrak{a}^n$ and therefore $uv = (a+\alpha)(b+\beta) = ab + \alpha b + a\beta + \alpha\beta \in ab + \mathfrak{a}^n \subseteq W$. That is we have found $uv \in W$ again, as required. □

Proof of (7.44):

We begin by verifying, that $R_{\mathfrak{a}}[t]$ truly is a sub-algebra of $R[t]$: It is clear, that $R_{\mathfrak{a}}[t]$ is an additive subgroup of $R[t]$ and that $\mathbf{1} \in R_{\mathfrak{a}}[t]$. The only not trivial part is that $R_{\mathfrak{a}}[t]$ is closed under multiplication. So consider any two $f, g \in R_{\mathfrak{a}}[t]$, then for any $n \in \mathbb{N}$ we have

$$(fg)[n] \;=\; \sum_{i=0}^{n} f[i]\, g[n-i] \;\in\; \sum_{i=0}^{n} \mathfrak{a}^i\, \mathfrak{a}^{n-i} \;=\; \mathfrak{a}^n$$

such that $fg \in R_{\mathfrak{a}}[t]$ again. And from this we also see, that ϱ is a homomorphism of rings. It also is clear from the construction of the Rees-algebra, that ϱ is surjective, as the n-th component of $(f_n + \mathfrak{a}^{n+1}) \in R(\mathfrak{a})$ is contained in $f_n \in \mathfrak{a}^n$. It also is clear, that $\varrho(g) = 0$ is equivalent, to

$$g \;\in\; \left\{ f \in R[t] \mid \forall\, n \in \mathbb{N} : f[n] \in \mathfrak{a}^{n+1} \right\}$$

so let us argue, that this truly is the ideal generated, by $\{\, a\mathbf{1} \mid a \in \mathfrak{a} \,\} \subseteq R_{\mathfrak{a}}[t]$. By construction the elements of this ideal are of the form $f = a_1 f_1 + \cdots + a_k f_k$ where $a_i \in \mathfrak{a}$ and $f_i \in R_{\mathfrak{a}}[t]$. Let us evaluate what this means

$$f[n] \;=\; \sum_{n=0}^{\infty} \left(a_1 f_1[n] + \ldots a_k f_k[n] \right)$$

As $f_i[n] \in \mathfrak{a}^n$ and $a_i \in \mathfrak{a}$ by assumption, this means $f[n] \in \mathfrak{a}^{n+1}$ and hence f is in the kernel of ϱ. And the same is true in the opposite direction: If $\varrho(f) = 0$, then $f[n] \in \mathfrak{a}^{n+1} = \mathfrak{a}\,\mathfrak{a}^n$. And thereby the product $\mathfrak{a}\,\mathfrak{a}^n$ contains elements of the form $a_1 b_1 + \cdots + a_k b_k$, where $a_i \in \mathfrak{a}$ and $b_i \in \mathfrak{a}^n$. As $f \in R[t]$ it is of finite degree and any $k(n)$ is finite, we find that f is a finite sum of terms of the form $a_i b_i t^n$, for some $a_i \in \mathfrak{a}$ and $b_i \in \mathfrak{a}^n$. But such sums are contained in the ideal generated by $\{\, a\mathbf{1} \mid a \in \mathfrak{a} \,\}$ in $R_{\mathfrak{a}}[t]$. □

Proof of (7.51):

(i) If $h \in A_d$ but $h \neq 0$ then the homogeneous decomposition $h = \sum_c h_c$ has precisely one non-zero entry $h = h_d$ at $c = d$ (by comparing coefficients). Thus $\deg(h) = \max\{\, d \,\}$ and this clearly is d.

(ii) If $f \in A_{\text{hom}}$ with $f \in A_d$ then we have just argued in (i) that $\deg(f) = \max\{\, d \,\} = d$. And likewise $\operatorname{ord}(f) = \min\{\, d \,\} = d$ which yields $\operatorname{ord}(f) = \deg(f)$. Conversely suppose $d := \operatorname{ord}(f) = \deg(f)$, then we use a homogeneous decomposition $f = \sum_c f_c$ again. By construction, if $c < d = \operatorname{ord}(f)$ or $d = \deg(d) < c$ then $f_c = 0$. Thus it only remains $f = f_d \in A_d$ and hence $f \in hogA$.

(iii) As $\operatorname{ord}(f)$ is the minimum and $\deg(f)$ is the maximum over the common set $\{\, d \in D \mid f_d \neq 0 \,\}$ it is clear, that $\operatorname{ord}(f) \leq \deg(f)$. Now let $a := \deg(f)$ and $b := \deg(g)$. Then (by construction of the degree) the homogeneous decompositions of f and g are of the form

$$f = \sum_{c \leq a} f_c \quad \text{and} \quad g = \sum_{d \leq b} g_d$$

Thus the product fg is given by a sum over two indexes $c \leq a$ and $d \leq b$. Assorting the (c,d) according to the sum $c + d$ we find that

$$fg \;=\; \left(\sum_{c \leq a} f_c \right) \left(\sum_{d \leq b} g_d \right) \;=\; \sum_{c \leq a} \sum_{d \leq b} f_c g_d \;=\; \sum_{e \in D} \sum_{c+d=e} f_c g_d$$

Note that thereby $f_c g_d \in A_{c+d} = A_e$. Thus we have found the homogeneous decomposition of fg again. But as D was assumed to be positive $c \leq a$ and $d \leq b$ implies $e = c + d \leq a + d \leq a + b$. Thus the homogeneous decomposition is of the following form

$$fg \;=\; \sum_{e \leq a+b} \left(\sum_{c+d=e} f_c g_d \right)$$

And this of course means $\deg(fg) \leq a + b = \deg(f) + \deg(g)$. The claim for the order can be shown in complete analogy. Just let $a := \operatorname{ord}(f)$ and $b := \operatorname{ord}(g)$. Then f and g can be written as

$$f = \sum_{c \geq a} f_c \quad \text{and} \quad g = \sum_{d \geq b} g_d$$

Thus in complete analogy to the above one finds that the homogeneous decomposition of fg is of the following form (which already yields $\operatorname{ord}(fg) \geq a + b = \operatorname{ord}(f) + \operatorname{ord}(g)$)

$$fg \;=\; \sum_{e \geq a+b} \left(\sum_{c+d=e} f_c g_d \right)$$

(iv) We commence with the proof given in (iii), that is $a = \deg(f)$ and $b = \deg(g)$. In particular $f_a \neq 0$ and $g_b \neq 0$. But as A is now assumed to be an integral domain this yields $f_a g_b \neq 0$. We have already found the homogeneous decomposition of fg to be

$$fg \;=\; \sum_{e \leq a+b} \left(\sum_{c+d=e} f_c g_d \right)$$

So let us take a look at the homogeneous component $(fg)_{a+b}$ of degree $a + b \in D$. Given any $c \leq a$ and $d \leq b$ we get the implication

$$c + d = a + b \quad \Longrightarrow \quad (c, d) = (a, b)$$

Because if we had $c \neq a$ then $c < a$ and hence $c + d < a + d \leq a + b$, as D was assumed to be strictly positive. Likewise $d \neq b$ would imply $c + d < a + b$ in contradiction to $c + d = a + b$. Thus the homogeneous component $(fg)_{a+b}$ is given to be

$$(fg)_{a+b} \;=\; \sum_{c+d=a+b} f_c g_d \;=\; f_a g_b \;\neq\; 0$$

In particular we find $\deg(fg) \geq a + b = \deg(f) + \deg(g)$ and hence $\deg(fg) = \deg(f) + \deg(g)$. By replacing the above implication with $c \geq a$, $d \geq b$ and $c + d = a + b$ implies $(c, d) = (a, b)$ the claim for the order $\operatorname{ord}(fg) = \operatorname{ord}(f) + \operatorname{ord}(g)$ can be proved in complete analogy.

(v) As D is strictly positive it already is integral, according to (7.6.(iii)). Hence by (7.48.(i)) we already know $1 \in A_0$ and hence $\deg(1) = 0$ according to (i). And as 1 is homogeneous we also get $\operatorname{ord}(1) = \deg(1) = 0$, according to (ii). Now suppose $f \in A^*$ is an invertible element of A. Then

we use (iv) to compute

$$0 \;=\; \deg(1) \;=\; \deg(ff^{-1}) \;=\; \deg(f)+\deg(f^{-1})$$

$$0 \;=\; \operatorname{ord}(1) \;=\; \operatorname{ord}(ff^{-1}) \;=\; \operatorname{ord}(f)+\operatorname{ord}(f^{-1})$$

And as $\operatorname{ord}(f) \leq \deg(f)$ and $\operatorname{ord}(f^{-1}) \leq \deg(f^{-1})$ (due to (iii)) the positivity of D can be used to find the following estimates

$$\begin{aligned} 0 \;&=\; \operatorname{ord}(f)+\operatorname{ord}(f^{-1}) \;\leq\; \deg(f)+\operatorname{ord}(f^{-1}) \\ &\leq\; \deg(f)+\deg(f^{-1}) \;=\; 0 \end{aligned}$$

In particular we find $\operatorname{ord}(f)+\operatorname{ord}(f^{-1}) = \deg(f)+\operatorname{ord}(f^{-1})$. Adding $\operatorname{ord}(f)$ this equation turns into $\operatorname{ord}(f) = \deg(f)$ and by (ii) again this means that $f \in hogA$ is homogeneous.

(vi) Let us suppose $h = fg$ for some $g \in A$. As $h \in hogA$ we have $h \neq 0$ and this also implies $f, g \neq 0$. We will assume that f was *not* homogeneous and derive a contradiction. Recall that by (iii) f not being homogeneous is equivalent to $\operatorname{ord}(f) < \deg(f)$. But if that was true we could use (iv) to find the contradiction

$$\begin{aligned} \operatorname{ord}(h) \;&=\; \operatorname{ord}(fg) \;=\; \operatorname{ord}(f)+\operatorname{ord}(g) \\ &<\; \deg(f)+\operatorname{ord}(g) \;\leq\; \deg(f)+\deg(g) \\ &=\; \deg(fg) \;=\; \deg(h) \;=\; \operatorname{ord}(h) \end{aligned}$$

□

Proof of (7.12):

(i) Consider any $b \in R$ and any polynomial $f \in R[t \mid A]$. Then for any $\gamma \in A$ we get the following computation

$$(f \cdot bt^0)[\gamma] \;=\; \sum_{\alpha+\beta=\gamma} f[\alpha]\, bt^0[\beta] \;=\; \sum_{\alpha+\beta=\gamma} f[\alpha]\, b\delta_{\beta,\gamma} \;=\; bf[\gamma]$$

In complete analogy we see, that $(bt^0 \cdot f)[\gamma] = bf[\gamma]$. And as this is true for any $\gamma \in A$ we have shown $f \cdot bt^0 = bf$ and $bt^0 \cdot f = bf$. In particular for $b = 1$ we get $f \cdot t^0 = f = t^0 \cdot f$. That is t^0 is the unit element of the ring $R[t \mid A]$ or shortly $t^0 = \mathbf{1}$.

(ii) In the proof of (i) (by taking $f = at^0$ for some $a \in R$) we have seen, that $(at^0) \cdot (bt^0) = (ab)t^0$ such that ι is multiplicative. And the additivity of ι is clear by construction of $R[t \mid A]$. But the injectivity of ι is trivial, as well.

(iii) Given $f \in R[\![t \mid A]\!]$ let us define $\iota(f) \in R[\![t \mid B]\!]$ to be $\iota(f)[\alpha] := f[\alpha]$ for $\alpha \in A$ and $\iota(f)[\beta] := 0$ for $\beta \in B \setminus A$. Then clearly $f \mapsto \iota(f)$ is injective and R-linear. Also $\iota(\mathbf{1}) = \mathbf{1}$, as $0 \in A$. It remains

to check the multiplicativity of ι: Consider any $\gamma \in B$, then

$$\big(\iota(f)\cdot\iota(g)\big)[\gamma] \;=\; \sum_{\alpha+\beta=\gamma} \begin{cases} f[\alpha] \text{ if } \alpha \in A \\ \quad 0 \text{ if } \alpha \notin A \end{cases} \begin{cases} g[\beta] \text{ if } \beta \in A \\ \quad 0 \text{ if } \beta \notin A \end{cases}$$

where the sum runs over all α and $\beta \in B$ with $\alpha+\beta=\gamma$. Yet all the summands vanish, unless $\alpha \in A$ and $\beta \in A$. And as A is a submonoid this also implies $\gamma = \alpha+\beta \in A$. Thus this is precisely $(f\cdot g)[\gamma]$ for $\gamma \in A$ and 0 if $\gamma \notin A$. Thus we find the multiplicativity

$$\big(\iota(f)\cdot\iota(g)\big)[\gamma] \;=\; \iota\big(f\cdot g\big)[\gamma]$$

(iv) The fact that $\overline{\varphi} : R[t \mid A] \to S[t \mid A]$ is a homomorphism of R-algebras is just a special case of (7.14) if we take $\sigma : A \to S[t \mid A]$ to be $\sigma(\alpha) := t^\alpha$. In case of the ring of formal power series $S[\![t \mid A]\!]$ the computations are literally the same.

Thus let us suppose φ is injective and $\overline{\varphi}(f) = \overline{\varphi}(g)$ for some $f, g \in R[\![t \mid A]\!]$. By definition of formal power series, this is $\overline{\varphi}(f)[\alpha] = \overline{\varphi}(g)[\alpha]$ for any $\alpha \in A$. And by construction this is $\varphi(f[\alpha]) = \varphi(g[\alpha])$. But as φ this implies $f[\alpha] = g[\alpha]$ for any $\alpha \in A$ and hence $f = g$. Thus $\overline{\varphi}$ also is injective.

And if φ is surjective and we are given any $g \in S[\![t \mid A]\!]$ then for any α we may choose $f[\alpha] \in R$ such that $\varphi(f[\alpha]) = g[\alpha]$. Then by construction we have $\overline{\varphi}(f) = g$ such that $\overline{\varphi}$ is surjective. In particular if φ is bijective then φ is both, injective and surjective and this is true for $\overline{\varphi}$, as well.

(v) Is obvious by the multiplicative property $t^\alpha\, t^\beta = t^{\alpha+\beta}$ of monomials, which has been shown in the remark preceding this proposition.

(vi) Let us first suppose A and B are solution-finite and consider any $a \in R$ and $f, g \in R[\![s \mid A]\!][\![t \mid B]\!]$. By construction we have $f[\beta] \in R[\![s \mid A]\!]$ for any $\beta \in B$. That is f is of the form

$$f \;=\; \sum_{\beta\in B} f[\beta]\, t^\beta \;=\; \sum_{\beta\in B} \left(\sum_{\alpha\in A} f[\beta]f[\alpha]\, s^\alpha \right) t^\beta$$

We have defined the isomorphism Φ by $\Phi(f) : (\alpha,\beta) \mapsto f[\beta]f[\alpha]$. In particular it is clear that Φ is bijective, as it only rearranges coefficients. So it only remains to prove its homomorphism properties: First of all it is clear, that Φ is additive, since

$$\begin{aligned} \Phi(f+g)[\alpha,\beta] &= (f+g)[\beta][\alpha] \\ &= \big(f[\beta]+g[\beta]\big)[\alpha] \\ &= f[\beta][\alpha] + g[\beta][\alpha] \\ &= \Phi(f)[\alpha,\beta] + \Phi(g)[\alpha,\beta] \end{aligned}$$

As A and B are solution-finite, so is $A \times B$, by (7.2). Therefore all the R-modules of formal power series involved are R-algebras. The R-linearity will then be a special case of the multiplicativity of Φ that we will prove next: Let $\alpha, \gamma, \varepsilon \in A$ and $\beta, \delta, \eta \in B$, then we get

$$\Phi(f\cdot g)[\varepsilon,\eta] \;=\; (f\cdot g)[\eta][\varepsilon]$$

$$
\begin{aligned}
&= \left(\sum_{\beta+\delta=\eta} f[\beta] \cdot g[\alpha] \right) [\varepsilon] \\
&= \sum_{\alpha+\gamma=\varepsilon} \sum_{\beta+\delta=\eta} f[\beta][\alpha] \cdot g[\alpha][\gamma] \\
&= \sum_{(\alpha,\beta)+(\gamma,\delta)=(\varepsilon,\eta)} f[\beta][\alpha] \cdot g[\alpha][\gamma]
\end{aligned}
$$

On the other hand, if we take a look at $\Phi(f) \cdot \Phi(g)$, then we find the multiplicativity $\Phi(f \cdot g) = \Phi(f) \cdot \Phi(g)$ as the left and right-hand side expressions agree in every coefficient over (ε, η)

$$
\begin{aligned}
\big(\Phi(f) \cdot \Phi(g)\big)[\varepsilon,\eta] &= \sum_{(\alpha,\beta)+(\gamma,\delta)=(\varepsilon,\eta)} \Phi(f)[\alpha,\beta] \cdot \Phi(g)[\gamma,\delta] \\
&= \sum_{(\alpha,\beta)+(\gamma,\delta)=(\varepsilon,\eta)} f[\beta][\alpha] \cdot g[\alpha][\gamma] \\
&= \Phi(f \cdot g)[\varepsilon,\eta]
\end{aligned}
$$

That is we have proved the isomorphy of the R-algebras $R[\![s \mid A]\!][\![t \mid B]\!]$ and $R[\![x \mid A \times B]\!]$. It is clear that Φ maps polynomials to polynomials: As Φ only rearranges the coefficients it does not change the number of non-zero entries. Therefore Φ is an isomorphism from $R[s \mid A][t \mid B]$ to $R[x \mid A \times B]$. And as the homomorphism property remains, even if A or B is not solution-finite, this is true for general A and B.

(vii) Let us first consider the case that R is an integral domain: We choose any two non-zero polynomials $0 \neq f, g \in R[t \mid A]$ and denote the coefficients on which f and g are non-zero by

$$
\begin{aligned}
\{\, \alpha_1, \ldots, \alpha_m \,\} &:= \{\, \alpha \in A \mid f[\alpha] \neq 0 \,\} \\
\{\, \beta_1, \ldots, \beta_n \,\} &:= \{\, \beta \in A \mid g[\beta] \neq 0 \,\}
\end{aligned}
$$

Without loss of generality we may assume $\alpha_1 < \cdots < \alpha_m$ and likewise $\beta_1 < \cdots < \beta_n$. Let us now abbreviate $\gamma := \alpha_1 + \beta_1$, then for any $i \in 1 \ldots m$ and $j \in 1 \ldots n$ proposition (7.6.(iv)) implies

$$
\alpha_i + \beta_j = \gamma \implies \alpha_i = \alpha_1 \text{ and } \beta_i = \beta_1
$$

We now assume $fg = 0$ and use the above implication to compute the γ-coefficient of fg, obtaining

$$
0 = (f\,g)[\gamma] = \sum_{\alpha_i+\beta_j=\gamma} f[\alpha_i]\, g[\beta_j] = f[\alpha_1]\, g[\beta_1]
$$

If now R is integral then $f[\alpha_1] = 0$ or $g[\beta_1] = 0$ in contradiction to the construction $f[\alpha_1]$ and $g[\beta_1] \neq 0$. But this ensures the direction (a) $\implies$ (b). The converse implication is clear due to the embedding $R \hookrightarrow R[t \mid A]$ in (ii) however.

(vii) Let us now prove that $R[t \mid A]$ is reduced, whenever R is reduced. That is we consider some polynomial $g \in R[t \mid A]$ such that $g^r = 0$ for some $r \in \mathbb{N}$ and have to prove $g = 0$. Let us start with $g \neq 0$, then we have to falsify the assumption $g^r = 0$. To do this let $\{\, \beta_1, \ldots, \beta_n \,\}$ be the set of $\beta \in A$ such that $g[\beta] \neq 0$ again. As before we may assume $\beta_1 < \cdots < \beta_n$. Then the polynomial

rule (1.41) tells us

$$g^r \;=\; \left(\sum_{j=1}^{n} g[\beta_j]\, t^{\beta_j}\right)^r \;=\; \sum_{|\alpha|=r} \binom{r}{\alpha} \prod_{j=1}^{r} \left(g[\beta_j]\, t^{\beta_j}\right)^{\alpha_j} \;=\; \sum_{|\alpha|=r} \binom{r}{\alpha} \left(\prod_{j=1}^{r} g[\beta_j]^{\alpha_j}\right) t^{\langle\alpha|\beta\rangle}$$

where the sum runs over all $\alpha \in \mathbb{N}^n$ such that $\alpha_1 + \cdots + \alpha_n = r$. In the last sum we denoted $\langle \alpha \mid \beta \rangle := \alpha_1\beta_1 + \cdots + \alpha_n\beta_n \in A$. It is clear that among all these α precisely $\alpha = (r, 0, \ldots, 0)$ yields the minimal $\langle \alpha \mid \beta \rangle = r\beta_1$. All the other α yield $r\beta_1 < \langle \alpha \mid \beta \rangle$ such that

$$g^r[r\beta_1] \;=\; g[\beta_1]^r$$

as for this $\alpha = (r, 0, \ldots, 0)$ the binomial coefficient is 1. Now, if we had $g^r = 0$ then this would imply $g[\beta_1]^r = 0$ and as R is reduced, this would imply $g[\beta_1] = 0$ in contradiction to our construction $g[\beta_1] \neq 0$. Thus we have falsified $g^r = 0$ and hence the implication (a) $\implies$ (b). The converse implication is clear due to the embedding $R \hookrightarrow R[t \mid A]$ in (ii) again.

(viii) First of all note that the assumption $L_\gamma := \{\, \alpha \in A \mid \alpha \leq \gamma \,\}$ being a finite set for any $\gamma \in A$ implies A to be solution-finite, by (7.6.(viii)) and hence $R[\![t \mid A]\!]$ is an R-algebra. Now consider any $f \in R[\![t \mid A]\!]$, then we can define

$$\operatorname{ord}(f) \;:=\; \min\{\, \alpha \in A \mid f[\alpha] \neq 0 \,\}$$

This is due to the following reasoning: Choose any $\gamma \in A$ with $f[\gamma] \neq 0$, then the set of all non-zero coefficients of f up to γ is $\{\, \alpha \in A \mid \alpha \leq \gamma \text{ and } f[\alpha] \neq 0 \,\} \subseteq L_\gamma$ a finite set. Let $\mu \in A$ be the minimum of this set. If now $\alpha \in A$ is any element with $f[\alpha] \neq 0$, then we distinguish two cases: If $\alpha \leq \gamma$, then we have $\mu \leq \alpha$ by minimality of μ. And if $\alpha > \gamma$ then $\mu \leq \gamma < \alpha$ also implies $\mu \leq \alpha$. Thus we have $\mu \leq \alpha$ for any α with $f[\alpha] \neq 0$, which means $\operatorname{ord}(f) = \mu$ exists.

Now if we are given any two formal power seires $f, g \in R[\![t \mid A]\!]$ with $f, g \neq 0$ let $\alpha_1 := \operatorname{ord}(f)$ and $\beta_1 := \operatorname{ord}(g)$. Then we can proceed as in (vii) above: If $\gamma := \alpha_1 + \beta_1$ then for any $\alpha, \beta \in A$ with $f[\alpha] \neq 0$ and $g[\beta] \neq 0$ we get

$$\alpha + \beta \;=\; \gamma \quad\Longrightarrow\quad \alpha \;=\; \alpha_1 \;\text{ and }\; \beta \;=\; \beta_1$$

by (7.6.(iv)) again. Thus we get $fg[\gamma] = f[\alpha_1]g[\beta_1]$ as before. Now if R is an integral domain and $fg = 0$ then this would imply $f[\alpha_1] = 0$ or $g[\beta_1] = 0$ a contradiction to $f \neq 0$ and $g \neq 0$. Thus $R[\![t \mid A]\!]$ is an integral domain, again.

In particular, we see by induction on r, that $f[r\alpha_1] = f[\alpha_1]^r$. Thus if R is reduced and $f^r = 0$ then we conclude $f[\alpha_1]^r = 0$ which turns into $f[\alpha_1] = 0$, a contradiction again. Thus if we start with a reduced ring R, then $R[\![t \mid A]\!]$ will be reduced, again. The converse implications are clear due to the embeddings $R \hookrightarrow R[t \mid A]$ in (ii) and $R[t \mid A] \hookrightarrow R[\![t \mid A]\!]$ by (iii).

□

Proof of (7.14):

It is obvious that the ring homomorphism σ_φ is uniquely determined by the above properties, as the monomials t^α form a basis of $R[t \mid A]$ and the compositions $+$ and $\cdot$ are expanded from the monomials. Thus

it only remains to show that σ_φ truly is a ring-homomorphism, but this is a straightforward computation - consider $f,g \in R[t \mid A]$, then we find

$$\begin{aligned}\sigma_\varphi(f)+\sigma_\varphi(g) &= \sum_{\alpha\in A}\varphi(f[\alpha])\,\sigma(\alpha) \;+\; \sum_{\alpha\in A}\varphi(g[\alpha])\,\sigma(\alpha)\\ &= \sum_{\alpha\in A}\varphi\big(f[\alpha]+g[\alpha]\big)\,\sigma(\alpha)\\ &= \sigma_\varphi(f+g)\end{aligned}$$

$$\begin{aligned}\sigma_\varphi(f)\cdot\sigma_\varphi(g) &= \left(\sum_{\alpha\in A}\varphi(f[\alpha])\,\sigma(\alpha)\right)\;\cdot\;\left(\sum_{\beta\in A}\varphi(g[\beta])\,\sigma(\beta)\right)\\ &= \sum_{\alpha\in A}\sum_{\beta\in A}\varphi\big(f[\alpha]\cdot g[\beta]\big)\,\sigma(\alpha+\beta)\\ &= \sum_{\gamma\in A}\varphi\left(\sum_{\alpha+\beta=\gamma} f[\alpha]\cdot g[\beta]\right)\sigma(\gamma)\\ &= \sigma_\varphi(fg)\end{aligned}$$

$$\begin{aligned}\sigma_\varphi(af) &= \left(\sum_{\alpha\in A}\varphi(af[\alpha])\,\sigma(\alpha)\right)\\ &= \sum_{\alpha\in A}\varphi(a)\cdot\varphi(f[\alpha])\,\sigma(\alpha)\\ &= \varphi(a)\cdot\sum_{\alpha\in A}\varphi(f[\alpha])\,\sigma(\alpha)\\ &= \varphi(a)\cdot\sigma_\varphi(f)\end{aligned}$$

□

Proof of (7.16):
Let $I := R\setminus\{\,0_R,1_R\,\}$ where 0_R and 1_R denote the zero resp. the unit element of R. Further let $A := \mathbb{N}^{\oplus I}$ be the commutative monoid over the index set I. Now take the polynomial ring

$$S \;:=\; \mathbb{Z}[t_a \mid a\in I]$$

As A can be turned into a positively ordered monoid $(A,+,\leq_{\text{lex}})$ according to (7.8) and $\mathbb{Z}$ is an integral domain, so is S due to proposition (7.12.(iv)). And clearly $\zeta : \mathbb{Z}\to R : k\mapsto k\cdot 1_R$ is a well-defined homomorphism of rings (which we used in section 2.9 to introduce the characteristic). And there is a well-defined homomorphism of monoids $\alpha : A\to R$, induced by expansion of $\zeta(\delta_a)=a$. By (7.14) we now find a well-defined homorphsim of rings $\varrho := \alpha_\zeta : S\to R$. And this ϱ clearly is surjective, since $\varrho(t_a)=a$. □

Proof of (7.54):

(i) The proof is based on a computation in which we evaluate $g(t) := f(t)\cdot(t-a)$. By definition of

the multiplication in $R[t]$ this is nothing but

$$\begin{aligned}\sum_{k=0}^{\infty} g[k]t^k &= \left(\sum_{k=0}^{\infty} f[k]t^k\right)(t-a)\\ &= \sum_{k=0}^{\infty} f[k]t^{k+1} - \sum_{k=0}^{\infty} af[k]t^k\\ &= \sum_{k=1}^{\infty} \big(f[k-1] - af[k]\big)\, t^k - af[0]\end{aligned}$$

So by comparing coefficients we find $g[0] = -af[0]$ and for any $k \geq 1$ also $g[k] = f[k-1] - af[k]$. Let us first deal with (b) $\implies$ (a): That is we assume that $\deg(f) = n-1$ and $f[n-1] = 1$. More explicitly for any $k \geq n$ we have $f[k] = 0$. Then for any $k > n$ we find that

$$\begin{aligned}g[n] &= f[n-1] - af[n] \;=\; 1 - a\cdot 0 \;=\; 1\\ g[k] &= f[k-1] - af[k] \;=\; 0 - a\cdot 0 \;=\; 0\end{aligned}$$

That is g is a monic polynomial of degree n, as we had claimed. Conversely for (a) $\implies$ (b) we have $g[n] = 1$ and $g[k] = 0$ for any $k > n$. Clearly $f \neq 0$, as else $g = 0$ which contradicts g being monic, as $R \neq 0$. Hence we may take $m := \deg(f) \in \mathbb{N}$. As $f[m+1] = 0$ we then get

$$g[m+1] \;=\; f[m] - af[m+1] \;=\; f[m] - a\cdot 0 \;=\; f[m] \;\neq\; 0$$

From this we conclude $\deg(g) \geq m+1 > \deg(f)$. And for any $k > m+1$ we have $k-1 > m$ and hence $f[k-1] = 0$ and $f[k] = 0$ such that we also find $\deg(g) \leq m+1$ from

$$g[k] \;=\; f[k-1] - af[k] \;=\; 0 - a\cdot 0 \;=\; 0$$

Together this means $n = \deg(g) = m+1$ such that $\deg(f) = m = n-1$. But g is monic such that $1 = g[n] = g[m+1] = f[m]$ which means, that f is monic, too. Together this is (b), as claimed.

(ii) Let us use division with remainder (2.67) to divide f by $t-a$ (which is possible, as $t-a$ is monic). That is we find polynomials q, $r \in R[t]$ such that $r = 0$ or $\deg(r) < \deg(t-a)$ and

$$f(t) \;=\; q(t)\cdot(t-a) + r(t)$$

If $r = 0$, then $r \in R$. But also $\deg(r) < \deg(t-a) = 1$ implies $\deg(r) = 0$, which is $r \in R$ again. In other words $r(t) = r$ is a constant. Let us now use (7.14) in the standard situation $S = R$, $\varphi = \mathbb{1}$ and $\sigma(k) = a^k$. As $\sigma_{\mathbb{1}}$ is a homomorphism or rings we get - for $f(a) := \sigma_{\mathbb{1}}(f)$

$$f(a) \;=\; q(a)\cdot(a-a) + r(a) \;=\; r(a)$$

But as $r(t) = r$ is a constant we have $r(a) = \mathbb{1}(r) = r$, as well. Hence the above representation $f(t) = q(t)(t-a) + r(t)$ turns into $f(t) = q(t)(t-a) + f(a)$, which is our claim precisely.

(iii) In the direction " $\implies$ " we use (ii) to write f as $f(t) = q(t)(t-a) + f(a)$ for some polynomial $q \in R[t]$. As $f(a) = 0$, by assumption, we already have $f(t) = q(t)(t-a)$, which is $(t-a) \mid f(t)$.

Conversely for " $\Longleftarrow$ " there is some $q(t) \in R[t]$ such that $f(t) = q(t)(t-a)$ As in (ii) we now use (7.14) in the standard situation $f(a) := \sigma_{\mathbb{1}}(f)$ again, then we find the claim from

$$f(a) \;=\; q(a)\cdot(a-a) \;=\; 0$$

(iv) Obviously induction on the number m of roots, is the way to go: The foundation $m = 1$ already is (iii). So let us proceed with the induction step, that is we assume $f(t) = (t-x_1)\dots(t-x_m)q(t)$ and have another root $f(x_{m+1}) = 0$ such that $x_{m+1} \neq x_i$ for any $i \in 1\dots m$. Then we find

$$0 \;=\; f(x_{m+1}) \;=\; (x_{m+1}-x_1)\dots(x_{m+1}-x_m)\,q(x_{m+1})$$

As all the $(x_{m+1}-x_i) \neq 0$ are non-zero and R is an integral domain, we conclude that $q(x_{m+1}) = 0$. Hence by (iii) there is some polynomial $p \in R[t]$ such that $q(t) = (t-x_{m+1})p(t)$. Replacing q with $(t-x_{m+1})p$ we find the desired representation of f:

$$f(t) \;=\; (t-x_1)\dots(t-x_m)(t-x_{m+1})\,p(t)$$

So let $\{\, x_1,\dots,x_m \,\} = \{\, x \in R \mid f(x) = 0 \,\}$ be the set of roots of f. As the x_i are pairwise distinct, we have just seen, that $f(t) = (t-x_1)\dots(t-x_m)q(t)$ for some $q(t)$. Clearly $q \neq 0$, as else $f = 0$. We now evaluate the degree of f and thereby find the claim

$$\deg(f) \;=\; \deg\big((t-x_1)\dots(t-x_m)\,q(t)\big) \;=\; m+\deg(q) \;\geq\; m$$

(v) Let $d := f-g \in R[t]$, then $\deg(d) \leq \max\{\deg(f),\deg(g)\}$ and for any $x \in R$ we find $f(x) = g(x)$ equivalent to $d(x) = 0$. Combining these arguments we find that, the number of roots of d exceeds the degree of d. Let us summarize:

$$\deg(d) \;\leq\; \max\{\deg(f),\deg(g)\} \;<\; \#\{\, x \in R \mid f(x) = g(x) \,\} \;=\; \#\{\, x \in R \mid d(x) = 0 \,\}$$

But if $d \neq 0$, then (iv) tells us, that the number of roots cannot exceed the degree of d. Due to this contradiction, we conclude $d = 0$ and hence $f = g$.

□

Proof of (7.56):
Property (i) is obvious and (iii) follows from (i) and (ii) immediately: If A is invertible, then $AA^{-1} = E = A^{-1}A$ with $E = \mathbb{1}_n$ again. But then we find $\varphi_{A^{-1}}\varphi_A = \varphi_{AA^{-1}} = \varphi_E = \mathbb{1}_S$ and $\varphi_A\varphi_{A^{-1}} = \varphi_{A^{-1}A} = \varphi_E = \mathbb{1}_S$ such that $\varphi_{A^{-1}} = \big(\varphi_A\big)^{-1}$. The only property that needs some explanation is (ii). And as the t_i generate $S = R[t_1,\dots,t_n]$ is suffices to check $\varphi_B\,\varphi_A(t_i) = \varphi_{AB}(t_i)$ in a short computation. Let $A = (a_{i,j})$ and $B = (b_{j,k})$, then

$$\begin{aligned}\varphi_B\varphi_A(t_i) \;&=\; \varphi_B\left(\sum_{j=1}^n a_{i,j}t_j\right) \;=\; \sum_{j=1}^n a_{i,j}\,\varphi_B(t_j) \;=\; \sum_{j=1}^n a_{i,j}\sum_{k=1}^n b_{j,k}\,t_k \\ &=\; \sum_{k=1}^n\left(\sum_{j=1}^n a_{i,j}b_{j,k}\right)t_k \;=\; \sum_{k=1}^n [AB]_{i,k}\,t_k \;=\; \varphi_{AB}(t_i)\end{aligned}$$

□

Proof of (7.57):

(i) We prove this by induction on n: For $n = 1$ let $m := \deg(f)$ be the degree of f. As $f \neq 0$ is homogeneous this only leaves $f(t_1) = f[m]\, t_1^m$ such that $f(1) = f[m] \neq 0$. For the induction stet we have to distinguish $m := \deg(f)$ and $d := \deg_1(f)$. By (7.40) we can write f in the form

$$f(t_1, \ldots, t_n) \;=\; \sum_{k=0}^{d} f_k(t_1, \ldots, t_{n-1})\, t_n^k$$

where f_k is a homogeneous polynomial of degree $m-k$ and $f_d \neq 0$. By induction hypothesis there are $a_2, \ldots, a_{n-1} \in F$ such that $f_d(1, a_2, \ldots, a_{n-1}) \neq 0$. Then

$$g(x) \;:=\; f(1, a_2, \ldots, a_{n-1}, x) \;=\; \sum_{k=0}^{d} f_k(1, a_2 \ldots, a_{n-1})\, x^k \;\in\; F[x]$$

is a polynomial of degree d over F, in the variable x. But as F is an integral domain, (7.54.(iv)) tells us, that g only has finitely many roots. Yet F is infinite, by assumption, hence there remains some $a_n \in F$, with $g(a_n) \neq 0$. This again is $f(1, a_2, \ldots, a_{n-1}, a_n) \neq 0$ and hence the induction step is completed.

(ii) Let again $m := \deg(f)$ be the degree of f and single out the homogeneous part of f of degree m. That is, we define

$$f_m \;:=\; \sum_{|\alpha|=m} f[\alpha]\, t_1^{\alpha_1} t_2^{\alpha_2} \ldots t_n^{\alpha_n}$$

Then by construction f_m is a homogeneous polynomial of degree m and as $\deg(f) = m$ we have $f_m \neq 0$. Hence by (i) there are $a_2, \ldots, a_n \in F$, such that $f_m(1, a_2, \ldots, a_n) \neq 0$. These elements will do the trick - we only have to provide the why of it. So let us compute

$$g(x_1) \;:=\; f\big(x_1, x_2 + a_2 x_1, \ldots, x_n + a_n x_1\big) \;=\; \sum_{|\alpha| \leq m} f[\alpha]\, x_1^{\alpha_1} \prod_{i=2}^{n} \big(x_i + a_i x_1\big)^{\alpha_i}$$

We now use the binomial rule to evaluate the $(x_i + a_i x_1)^{\alpha_i}$. As *monic* is being decided on the highest term, we are only interested in the leading coefficients

$$\big(x_i + a_i x_1\big)^{\alpha_i} \;=\; \sum_{r=0}^{\alpha_i} \binom{\alpha_i}{r} x_i^{\alpha_i - r} a_i^r x_1^r \;=\; a_i^{\alpha_i} x_1^{\alpha_i} + \text{lower terms in } x_1$$

Inserting this in $g(x_1)$ we find the following equalities for f by straightforward computation

$$\begin{aligned}
g(x_1) \;&=\; \sum_{|\alpha| \leq m} f[\alpha]\, a_2^{\alpha_2} \ldots a_n^{\alpha_n} x_1^{\alpha_1 + \alpha_2 + \cdots + \alpha_n} + \text{lower terms in } x_1 \\
&=\; \sum_{|\alpha| \leq m} f[\alpha]\, (1, a_2, \ldots, a_n)^{\alpha} x_1^{|\alpha|} + \text{lower terms in } x_1 \\
&=\; \left(\sum_{|\alpha| = m} f[\alpha]\, (1, a_2, \ldots, a_n)^{\alpha} \right) x^m + \text{lower terms in } x_1 \\
&=\; f_m(1, a_2, \ldots, a_n)\, x^m + \text{lower terms in } x_1
\end{aligned}$$

But by construction $f_m(1, a_2, \ldots, a_n) \neq 0$ such that we can take $a := f_m(1, a_2, \ldots, a_n)^{-1}$ and thereby have $ag(x_1) = x^m +$ lower terms in x_1. But this is the claim: $ag(x_1) \in R[x_1]$ is monic.

(iii) As $f \neq 0$ the set $A := \{\, \alpha \in \mathbb{N}^n \mid f[\alpha] \neq 0 \,\}$ is finite. In particular $N := \max\{\, \alpha_i \mid \alpha \in A, i \in 1 \ldots n \,\}$ is a finite number. For any $i \in 1 \ldots n$ now define

$$m_i \;:=\; (N+1)^{i-1}$$

That is: for any $\alpha \in (1 \ldots N)^n$ the string $\alpha_n \ldots \alpha_2 \alpha_1$ is the $(N+1)$-adic representation of the number $\langle m \mid \alpha \rangle$. This is to say we get

$$\langle m \mid \alpha \rangle \;=\; \sum_{i=1}^{n} \alpha_i (N+1)^{i-1}$$

In particular $\alpha \mapsto \langle m \mid \alpha_i \rangle$ is injective, as $\langle m \mid \alpha \rangle$ is a number that encodes $\alpha_n \ldots \alpha_2 \alpha_1$. Formally this follows from $\alpha_1 m_1 < \alpha_2 m_2 < \cdots < \alpha_n m_n$ such that we can regain the α_i by *div* and *mod* $N+1$. As $A \subseteq (1 \ldots N)^n$ we have an injective map

$$A \hookrightarrow \mathbb{N} \;:\; \alpha \mapsto \langle m \mid \alpha \rangle$$

And as A is finite there has to be a uniquely determined $\alpha^* \in A$ such that $\langle m \mid \alpha^* \rangle$ is maximal, that is $\langle m \mid \alpha \rangle < \langle m \mid \alpha^* \rangle$ for any $\alpha \in A$ with $\alpha \neq \alpha*$. Now regard

$$g(x_1) \;:=\; f\big(x_1, x_2 + x_1^{m_2}, \ldots, x_n + x_1^{m_n}\big) \;=\; \sum_{\alpha \in A} f[\alpha]\, x_1^{\alpha_1} \prod_{i=2}^{n} \big(x_i + x_1^{m_i}\big)^{\alpha_i}$$

Again we evaluate any $(x_i + x_1^{m_i})^{\alpha_i}$ using the binomial rule. As *monic* is being decided on the highest term, we are only interested in the leading coefficients again

$$\big(x_i + x_1^{m_1}\big)^{\alpha_i} \;=\; \sum_{r=0}^{\alpha_i} \binom{\alpha_i}{r} x_i^{\alpha_i - r} x_1^{m_i r} \;=\; x_1^{m_i \alpha_i} + \text{lower terms in } x_1$$

Inserting this in $g(x_1)$ we find the following equalities for f. Also note that $m_1 = 1$ such that $\alpha_1 + m_2\alpha_2 + \cdots + m_n\alpha_n = \langle m \mid \alpha \rangle$ which enables us to compute

$$\begin{aligned} g(x_1) \;&=\; \sum_{\alpha \in A} f[\alpha]\, x_1^{\alpha_1 + m_2\alpha_2 + \cdots + m_n\alpha_n} + \text{lower terms in } x_1 \\ &=\; \sum_{\alpha \in A} f[\alpha]\, x_1^{\langle m \mid \alpha \rangle} + \text{lower terms in } x_1 \\ &=\; f[\alpha^*]\, x_1^{\langle m \mid \alpha^* \rangle} + \text{lower terms in } x_1 \end{aligned}$$

As $\alpha^* \in A$ we have $f[\alpha^*] \neq 0$ and therefore we can take $a := f[\alpha^*]^{-1}$ and thereby have $ag(x_1) = x^{\langle m \mid \alpha^* \rangle} +$ lower terms in x_1. But this is the claim: $ag(x_1) \in R[x_1]$ is monic.

□

Proof of (7.58):

(i) Let us first prove that in case of an integral domain R the determinant of the Vandermonde matrix

truly has the form given in the claim: To do this let us first consider the case that there are some $i < j \in 1 \dots n$ such that $x_i = x_j$ are equal. In this case two separate rows of the Vandermonde matrix are equal and hence the determinant is zero. On the other hand the product vanishes as well, as $x_j - x_i = 0$ and hence

$$\det\left(\mathrm{Van}(x_1, \dots, x_n)\right) \;=\; 0 \;=\; \prod_{1 \leq i < j \leq n} (x_j - x_i)$$

Thus let us assume that for any $i \neq j \in 1 \dots n$ the elements $x_i \neq x_j$ are distinct. We now use induction on the number n - the case $n = 1$ is true, as in this case $\mathrm{Van}(x_1) = (1)$ such that we have $\det(\mathrm{Van}(x_1)) = 1$. But also the set $\left\{ (i,j) \in (1 \dots n)^2 \mid i < j \right\} = \emptyset$ is empty and the product over the empty set has been defined to be 1. However, to eliminate all doubt, we also found the induction on $n = 2$, in this case

$$\det \begin{pmatrix} 1 & x_1 \\ 1 & x_2 \end{pmatrix} \;=\; (x_2 - x_1) \;=\; \prod_{1 \leq i < j \leq 2} (x_j - x_i)$$

is plain to see. In the induction step for $n \geq 2$ we pick up a variable z and regard the polynomial ring $R \subseteq R' := R[z]$ instead. Then we append the n-tuple $x := (x_1, \dots, x_n) \in R^n$ to $x' := (x_1, \dots, x_n, z) \in (R')^{n+1}$ and define the polynomial $h \in R' = R[z]$ to be the following

$$h(z) \;:=\; \det\left(\mathrm{van}(x')\right) \;=\; \det \begin{pmatrix} 1 & x_1 & \cdots & x_1^n \\ \vdots & \vdots & & \vdots \\ 1 & x_n & \cdots & x_n^n \\ 1 & z & \cdots & z^n \end{pmatrix}$$

We now use the formula of Laplace (4.55.(v)) to evaluate this determinant by expanding along the lowest row. For sake of easy readability let us use the common abbreviation $|A| := \det(A)$ of a determinant. Then expansion yields the following formula

$$h(y) \;=\; (-1)^n \begin{vmatrix} x_1 & \cdots & x_1^n \\ \vdots & & \vdots \\ x_n & \cdots & x_n^n \end{vmatrix} + \cdots + \begin{vmatrix} 1 & \cdots & x_1^{n-1} \\ \vdots & & \vdots \\ 1 & \cdots & x_n^{n-1} \end{vmatrix} z^n$$

From this we see that h is a polynomial of degree n in z. We also see, that the leading coefficient of h is the determinant of the Vandermonde matrix of x. By induction hypothesis, this is

$$\Delta \;:=\; \mathrm{lc}(h) \;=\; \det\left(\mathrm{Van}(x)\right) \;=\; \prod_{1 \leq i < j \leq n} (x_j - x_i)$$

But from the definition of h it is clear, that $h(x_i) = 0$, as for $z = x_i$ the last row is just a copy of the i-th row and hence the determinant vanishes. Recall that we assumed the x_i to be pairwise distinct, that is we have found n distinct roots of the polynomial h of degree n. As R is an integral domain (7.54.(iv)) tells us, that h splits into linear factors

$$h(z) \;=\; \Delta\,(z - x_1) \dots (z - x_n)$$

Now $h(z)$ finally is the determinant of the Vandermonde matrix of x' once we insert $z = x_{n+1}$. Doing this we finally find the claim for $n+1$, as we then compute

$$\begin{aligned} h(x_{n+1}) &= \det(\mathrm{van}(x_1,\ldots,x_n,x_{n+1})) \\ &= \left(\prod_{1\le i<j\le n}(x_j - x_i)\right)(x_{n+1}-x_1)\ldots(x_{n+1}-x_n) \\ &= \prod_{1\le i<j\le n+1}(x_j - x_i) \end{aligned}$$

(ii) By construction we have $\deg(L_j) = n-1$, as any $t - x_i$ is a monic polynomial of degree 1. Hence we have $L_j \in \mathcal{P}_n$. Let us first prove that the L_j form a linearly independent subset of $\mathcal{P}_n$. That is we assume that

$$a_1 L_1(t) + \cdots + a_n L_n(t) \;=\; \mathbf{0} \;\in\; R[t]$$

for some $a_j \in R$. As we have $L_j(x_i) = \delta_{i,j}$ we may insert x_i into this equation and thereby find $0 = \mathbf{0}(x_i) = \sum_j a_j L_j(x_i) = a_i$. As this is true for any $i \in 1\ldots n$ this is the linear independence. Now let $f := \sum_j y_j L_j \in \mathcal{P}_n$ then by the same reasoning we get

$$f(x_i) \;=\; \sum_{j=1}^{n} y_j\, L_j(x_i) \;=\; \sum_{j=1}^{n} y_j\, \delta_{i,j} \;=\; y_i$$

Given any other polynomial $g \in \mathcal{P}_n$ let $y_i := g(x_i)$ and build up f as before $f := \sum_j y_j L_j$. Then we have $g(x_i) = y_i = f(x_i)$, that is f and g agree at n locations $x_1,\ldots,x_n$. As both are of degree $\deg(g)$, $\deg(f) < n$ we find from (7.54.(v)) that $f = g$. Hence the set $\{L_1,\ldots,L_n\}$ also is a generating set, of $\mathcal{P}_n$ and hence a basis.

(iii) If we insert x_i into the ansatz $f = a_0N_0 + a_1N_1 + \cdots + a_{n-1}N_{n-1}$ this equation turns into $y_i = a_0N_0(x_i) + a_1N_1(x_i) + \cdots + a_{n-1}N_{n-1}(x_i)$. If we combine these n equations into a single matrix equation, this reads as

$$\begin{pmatrix} N_0(x_1) & N_1(x_1) & N_2(x_1) & \cdots & N_{n-1}(x_1) \\ N_0(x_2) & N_1(x_2) & N_2(x_2) & \cdots & N_{n-1}(x_2) \\ \vdots & \vdots & \vdots & & \vdots \\ N_0(x_n) & N_1(x_n) & N_2(x_n) & \cdots & N_{n-1}(x_n) \end{pmatrix} \begin{pmatrix} a_0 \\ a_1 \\ \vdots \\ a_{n-1} \end{pmatrix} = \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix}$$

However $N_0(t) = \mathbf{1}$ such that $N_0(x_i) = 1$ for any $i \in 1\ldots n$. And it also is clear that $N_j(x_i) = 0$ whenever $i \le j$, by construction of the $N_j(t)$. Hence this matrix is truly reduced to a lower triangular matrix, as given in the claim of the Newtonian interpolation method. The determinant of this lower triangular matrix truly is

$$\prod_{j=1}^{n} N_{j-1}(x_j) \;=\; \prod_{j=1}^{n}\prod_{i=1}^{j-1}(x_j - x_i) \;=\; \prod_{1\le i<j\le n}(x_j - x_i)$$

□

Proof of (7.59):

(i) As F is a field, it also is an integral domain. And as the x_i are pairwise distinct, the determinant of the Vandermonde matrix $\mathrm{Van}(x_1,\ldots,x_n)$ is non-zero, as any factor $x_j - x_i \neq 0$ is non-zero

$$\det\Big(\mathrm{Van}(x_1,\ldots,x_n)\Big) \;=\; \prod_{1\leq i<j\leq n}(x_j - x_i) \;\neq\; 0$$

In a field F this means, that the determinant is invertible and hence the Vandermonde-matrix is invertible, by (4.63.(ii)). Then we find a polynomial f satisfying (1) and (2) by (7.58.(i)). Its coefficients are given to be

$$\begin{pmatrix} f[0] \\ f[1] \\ \vdots \\ f[n-1] \end{pmatrix} = \begin{pmatrix} 1 & x_1 & \cdots & x_1^{n-1} \\ 1 & x_2 & \cdots & x_2^{n-1} \\ \vdots & \vdots & & \vdots \\ 1 & x_n & \cdots & x_n^{n-1} \end{pmatrix}^{-1} \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix}$$

(ii) If F is finite, say $F = \{ x_0,\ldots,x_n \}$, and $u : F \to F$ is any function, then let $y_i := u(x_i)$. By (i) there is a polynomial $f \in F[t]$ of degree $\deg(f) \leq n$ satisfying $f(x_i) = y_i$ for any $i \in 0\ldots n$. In particular $P_f = u$ and hence P is surjective. Yet $\#\mathbb{F}(F,F) = (n+1)^{n+1}$ is a finite set, whereas $F[t] = \mathbb{F}(\mathbb{N},F)$ is infinite. In particular $P : F[t] \to \mathcal{F}(F,F)$ cannot be injective.

If F is infinite then we consider two polynomials $f, g \in F[t]$ such that $P_f = P_g$. That is $f(x) = g(x)$ for any $x \in F$ and hence $\{ x \in F \mid f(x) = g(x) \} = F$ is infinite. In particular this set has more elements than the degrees of f and g, such that we get $f = g$ from (7.54.(v)). That is P is injective. Now define the function $u : F \to F$ by $u(0) := 1$ and $u(x) := 0$ for any $x \in F^*$. Suppose there was a polynomial $f \in F[t]$ such that $P_f = u$, then f has infinitely many roots $\mathbb{V}(f) = F^*$. In particular $f = 0$ by (7.54.(iv)). But then $f(0) = 0 \neq 1 = u(0)$, a contradiction. Hence there is no $f \in F[t]$ with $P_f = u$, such that P is not surjective.

□

Proof of (7.61):

(ii) As $0(x) = 0$ for any $x \in R^I$ we clearly have $0 \in \mathbb{I}(X)$. Now consider $f, g \in \mathbb{I}(X)$. That is for any $x \in X$ we have $f(x) = 0 = g(x)$. In particular $(f+g)(x) = f(x) + g(x) = 0 + 0 = 0$ and $(-f)(x) = -f(x) = -0 = 0$ such that $f+g$, $-f \in \mathbb{I}(X)$ again. And for any $h \in R[t_i \mid i \in I]$ we get $(fh)(x) = f(x)h(x) = 0 \cdot h(x) = 0$ such that also $fh \in \mathbb{I}(X)$. Altogether $\mathbb{I}(X)$ is an ideal.

Now assume that $\mathrm{NIL}(R) = 0$ and consider some $f \in \sqrt{\mathbb{I}(X)}$. That is $f^k \in \mathbb{I}(X)$ for some $k \in \mathbb{N}$. Then for any $x \in X$ we get $0 = f^k(x) = f(x)^k$. That is $f(x) \in R$ is nilpotent and hence $f(x) = 0$ by $\mathrm{NIL}(R) = 0$. As $x \in X$ has been arbitrary this is $f \in \mathbb{I}(X)$ and the converse inclusion is true in general. Thus $\mathbb{I}(X)$ then is a radical ideal.

(iii) As $F \subseteq \mathfrak{a}$ we clearly have $\mathbb{V}(\mathfrak{a}) \subseteq \mathbb{V}(F)$. Conversely consider any $x \in \mathbb{V}(F)$. If now $f \in \mathfrak{a}$, then f is of the form $f = g_1 f_1 + \cdots + g_n f_n$ for some $f_\lambda \in F$. And hence, as any $f_\lambda(x) = 0$ we get $f(x) = g_1(x)\,0 + \cdots + g_n(x)\,0 = 0$, which implies $x \in \mathbb{V}(\mathfrak{a})$.

Now assume that $\mathrm{NIL}(R) = 0$, as $\mathfrak{a} \subseteq \sqrt{\mathfrak{a}}$ we again get $\mathbb{V}(\sqrt{\mathfrak{a}}) \subseteq \mathbb{V}(\mathfrak{a})$. Conversely consider any $x \in \mathbb{V}(\mathfrak{a})$. If now $f \in \sqrt{\mathfrak{a}}$, then there is some $k \in \mathbb{N}$ such that $f^k \in \mathfrak{a}$ and hence $f(x)^k = f^k(x) = 0$. But as $\mathrm{NIL}(R) = 0$, this implies $f(x) = 0$ and hence $x \in \mathbb{V}(\sqrt{\mathfrak{a}})$.

(iv) For any $X \subseteq Y \subseteq R^I$ it is clear that $\mathbb{I}(Y) \subseteq \mathbb{I}(X)$, as then $f(x) = 0$ for any $x \in Y$ implies $f(x) = 0$ for any $x \in X$, too. And likewise $\mathfrak{a} \subseteq \mathfrak{b}$ implies $\mathbb{V}(\mathfrak{b}) \subseteq \mathbb{V}(\mathfrak{a})$, as then $f(x) = 0$ for any $f \in \mathfrak{b}$ implies $f(x) = 0$ for any $f \in \mathfrak{a}$, too.

By (0.22) property (b) it suffices to check $X \subseteq \mathbb{VI}(X)$ and $F \subseteq \mathbb{IV}(F)$ for any $X \subseteq R^I$ and $F \subseteq R[t_i \mid i \in I]$ respectively. But if $x \in X$ and $f \in \mathbb{I}(X)$ then it is clear that $f(x) = 0$ such that $x \in \mathbb{V}(f)$ again. But as this is true for any $x \in X$ and any $f \in \mathbb{I}(X)$ this already is $X \subseteq \mathbb{VI}(X)$. Likewise if $f \in F$ and $x \in \mathbb{V}(F)$, then $f(x) = 0$ such that $f \in \mathbb{I}(x)$ again.

(i) $f \in \mathbb{I}(X)$ is $\{f\} \subseteq \mathbb{I}(X)$ which implies $\mathbb{VI}(X) \subseteq \mathbb{V}(f)$. But as we have seen $X \subseteq \mathbb{VI}(X)$ in (iv) this implies $X \subseteq \mathbb{V}(f)$. Again this means $f(x) = 0$ for any $x \in X$ and hence $f \in \mathbb{I}(X)$.

$x \in \mathbb{V}(F)$ is $\{x\} \subseteq \mathbb{V}(F)$ which implies $\mathbb{IV}(F) \subseteq \mathbb{I}(x)$. But as we have seen $F \subseteq \mathbb{IV}(F)$ in (iv) this implies $F \subseteq \mathbb{I}(x)$. Again this means $f(x) = 0$ for any $f \in F$ and hence $x \in \mathbb{V}(F)$.

(v) Clearly $\mathbb{V}(0) = R^I$, as for any $x \in R^I$ we have $0(x) = 0$. Similarly $\mathbb{V}(R[t_i \mid i \in I]) = \emptyset$, as for any $x \in R^I$ we have $\mathbf{1}(x) = 1$ and $1 \neq 0$, as R is an integral domain. The next claim is

$$\mathbb{V}(\mathfrak{a}_1 \cdot \ldots \cdot \mathfrak{a}_n) \quad \subseteq \quad \mathbb{V}(\mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_n) \quad \subseteq \quad \mathbb{V}(\mathfrak{a}_1) \cup \cdots \cup \mathbb{V}(\mathfrak{a}_n)$$

As for any $\lambda \in 1 \ldots n$ we have the inclusions $\mathfrak{a}_1 \ldots \mathfrak{a}_n \subseteq \mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_n \subseteq \mathfrak{a}_\lambda$ the algebraic sets satisfy the converse inclusions $\mathbb{V}(\mathfrak{a}_\lambda) \subseteq \mathbb{V}(\mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_n) \subseteq \mathbb{V}(\mathfrak{a}_1 \ldots \mathfrak{a}_n)$. And as this is true for any $\lambda \in 1 \ldots n$ we get $\mathbb{V}(\mathfrak{a}_1) \cup \cdots \cup \mathbb{V}(\mathfrak{a}_n) \subseteq \mathbb{V}(\mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_n)$. Now suppose R is an integral domain, then we even get $\mathbb{V}(\mathfrak{a}_1 \ldots \mathfrak{a}_n) = \mathbb{V}(\mathfrak{a}_1) \cup \cdots \cup \mathbb{V}(\mathfrak{a}_n)$, because of: Suppose there was some $x \in \mathbb{V}(\mathfrak{a}_1 \ldots \mathfrak{a}_n)$ such that for any $\lambda \in 1 \ldots n$ we had $x \notin \mathbb{V}(\mathfrak{a}_\lambda)$. That is there is some $f_\lambda \in \mathfrak{a}_\lambda$ such that $f_\lambda(x) \neq 0$. But as R is an integral domain, this implies $(f_1 \ldots f_n)(x) = f_1(x) \ldots f_n(x) \neq 0$. Yet $f_1 \ldots f_n \in \mathfrak{a}_1 \ldots \mathfrak{a}_n$ such that we also have $(f_1 \ldots f_n)(x) = 0$. This contradiction is solved by concluding $x \in \mathbb{V}(\mathfrak{a}_\lambda)$ for some $\lambda \in 1 \ldots n$. So we will next prove

$$\mathbb{V}\left(\sum_{\lambda \in \Lambda} \mathfrak{a}_\lambda\right) \quad = \quad \bigcap_{\lambda \in \Lambda} \mathbb{V}(\mathfrak{a}_\lambda)$$

where R need not be an integral domain, any longer. The inclusion "$\subseteq$" is clear, as for any $\mu \in \Lambda$ we have $\mathfrak{a}_\mu \subseteq \sum_\lambda \mathfrak{a}_\lambda$ and hence the converse inclusion for the algebraic sets. For the converse inclusion consider any $x \in \bigcap_\lambda \mathbb{V}(\mathfrak{a}_\lambda)$ and any $f \in \sum_\lambda \mathfrak{a}_\lambda$. That is f is of the form $f = f_1 + \cdots + f_k$ for some $f_j \in \mathfrak{a}_{\lambda(j)}$. Then clearly $f(x) = f_1(x) + \cdots + f_k(x) = 0$, such that we also get $x \in \mathbb{V}(\sum_\lambda \mathfrak{a}_\lambda)$.

Thus we have proved all the claims for algebraic sets and we turn our attention to the vanishing ideals: As with algebraic sets $\emptyset \subseteq R^I$ poses no restriction on polynomials and hence we have $\mathbb{I}(\emptyset) = R[t_i \mid i \in I]$. And as $X_\lambda \subseteq \bigcup_\lambda X_\lambda$ - we have $\mathbb{I}(\bigcup_\lambda X_\lambda) \subseteq \mathbb{I}(X_\lambda)$ for any $\lambda \in \Lambda$ such that $\mathbb{I}(\bigcup_\lambda X_\lambda) \subseteq \bigcap_\lambda \mathbb{I}(X_\lambda)$. And if conversely $f \in \bigcap_\lambda \mathbb{I}(X_\lambda)$ then for any $x \in \bigcup_\lambda X_\lambda$ there is some $\mu \in \Lambda$ with $x \in X_\mu$ and hence $f \in \mathbb{I}(X_\mu)$ such that $f(x) = 0$. Finally regard any $f \in \sum_\lambda \mathbb{I}(X_\lambda)$, that is f is of the form $f = f_1 + \cdots + f_k$ for some $f_j \in \mathbb{I}(X_{\lambda(j)})$. If now $x \in \bigcap_\lambda X_\lambda$ then $f(x) = f_1(x) + \cdots + f_k(x) = 0$ and hence $f \in \mathbb{I}(\bigcap_\lambda X_\lambda)$.

(vi) If $R \neq 0$, then $1 \neq 0$ And hence we get $\mathbf{1}(x) = 1 \neq 0$ for any $x \in R^I$. And as $\mathbf{1} \in R[t_i \mid i \in I]$ this implies $\mathbb{V}(R[t_i \mid i \in I]) = \emptyset$. If R is an integral domain, then $R \neq 0$ is part of the definition.

Now suppose R is an infinite integral domain, then we wish to prove $\mathbb{I}(R^I) = 0$. That is we consider any $f \in \mathbb{I}(R^I)$, which is $\mathbb{V}(f) = R^I$, and have to show $f = 0$. As $f \in R[t_i \mid i \in I]$ in truth it is contained in some finite polynomial ring, that is $f \in R[t_i \mid i \in \omega]$ for some finite subset $\omega \subseteq I$, according to (7.23.(i)). For ease of notation let $\omega = \{1, \ldots, n\}$ and use induction on n: For $n = 1$ we have $f \in R[t_1]$ a polynomial in one variable over R. But for $f \in R[t_1]$ with $f \neq 0$ we know $\#\mathbb{V}(f) \leq \deg(f)$, which is finite, due to (7.54.(vi)). But as R is infinite and $\mathbb{V}(f) = R$ the set $\mathbb{V}(f)$ is infinite and this can only mean $f = 0$. Now for the induction step $n \geq 2$: Then we define $f_1(t_1) := f(t_1, 0, \ldots, 0) \in R[t_1]$. This yields $f_1(x_1) = f(x_1, 0, \ldots, 0) = 0$ for any $x_1 \in R$ and hence $f_1 = 0$ by the case $n = 1$. Thus f actually only depends on the variables $f(t_2, \ldots, t_n)$, so by induction hypothesis we get $f = 0$ again.

□

Proof of (7.62):

(i) As $\mathbb{VI}(X)$ is a closed set by construction and $X \subseteq \mathbb{VI}(X)$, it is clear, that $\overline{X} \subseteq \mathbb{VI}(X)$. Conversely, if $C \subseteq R^I$ is a closed set, then C is of the form $C = \mathbb{V}(\mathfrak{a})$ for some $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R[t_i \mid i \in I]$. Now, if $X \subseteq C$, then this implies $\mathbb{I}(C) \subseteq \mathbb{I}(X)$ from which we get $\mathbb{VI}(X) \subseteq \mathbb{VI}(C)$. Due to the Galois connection (7.61.(iv)) we have $\mathbb{VI}(C) = \mathbb{VIV}(\mathfrak{a}) = \mathbb{V}(\mathfrak{a}) = C$ and thereby $\mathbb{VI}(X) \subseteq C$. Thus $\mathbb{VI}(X)$ is contained in any closed set above X and this implies $\mathbb{VI}(X) \subseteq \overline{X}$, too.

(ii) If $\mathfrak{a} = 0$ then $\mathbb{V}(\mathfrak{a}) = R^I$ is clear. Conversely, if $\mathbb{V}(\mathfrak{a}) = R^I$ then $\mathfrak{a} \subseteq \mathbb{IV}(\mathfrak{a}) = \mathbb{I}(R^I) = 0$, according to (7.61.(iv)) and (7.61.(vi)). But $\mathfrak{a} \subseteq 0$ means $\mathfrak{a} = 0$.

□

Proof of (7.66):
The proof of all these statements relies in short, uninstructive computations. Thereby every statement is an easy consequence of the previous one and the reader looses nothing if he skips the proof entirely.

(i) By definition $s_k^{(n)}$ is a sum of terms $t_{\alpha(1)} \ldots t_{\alpha(k)}$ where $\alpha \in \mathrm{Asc}(k, n)$. Any of these terms is of degree k and hence $s_k^{(n)}$ is of degree k, as well.

(i) Let us abbreviate $s_k := s_k^{(n)}$ and $s := (s_1, \ldots, s_n) \in R[t_1, \ldots, t_n]^n$. Then in (i) we have seen $\deg(s_k) = k$ and hence for a monomial $f = t^\alpha$ where $\alpha \in \mathbb{N}^n$ the claim is straightforward to see

$$\deg\big(t^\alpha(s)\big) \;=\; \deg\big(s^\alpha\big) \;=\; \sum_{k=1}^{n} \deg\big(s_k^{\alpha_i}\big) \;=\; \sum_{k=1}^{n} \alpha_k \cdot k \;=\; \mathrm{wgt}\big(t^\alpha\big)$$

Thus for an arbitrary polynomial $f \in R[t_1, \ldots, t_n]$ this computation is inherited, as both, the degree and the weight, are defined to be the maximum among all $\alpha \in \mathbb{N}^n$ with $f[\alpha]$. Formally

$$\begin{aligned} \deg(f(s)) &= \max\{\, \deg(s^\alpha) \mid \alpha \in \mathbb{N} \text{ and } f[\alpha] \neq 0 \,\} \\ &= \max\{\, \mathrm{wgt}(t^\alpha) \mid \alpha \in \mathbb{N} \text{ and } f[\alpha] \neq 0 \,\} \;=\; \mathrm{wgt}(f) \end{aligned}$$

(ii) If $k = 1$ then $s_1^{(n)} = t_1 + \cdots + t_n = (t_1 + \cdots + t_{n-1}) + 1 \cdot t_n$ which is $s_1^{(n-1)} + s_0^{(n-1)} \cdot t_n$ again. Hence we may continue with $k \geq 2$. Clearly, for $n \geq 2$, we can decompose $\mathrm{Asc}(k, n)$ into two separate parts: We either have $\alpha(k) = n$ or not. If not, then $\alpha \in \mathrm{Asc}(k, n-1)$ and if $\alpha(k) = n$,

then β is of the form $\alpha = (\alpha', n)$ where $\alpha' = (\alpha(1), \ldots, \alpha(n-1)) \in \mathrm{Asc}(k-1, n-1)$. Thus we have established a disjoint union

$$\mathrm{Asc}(k,n) \;=\; \mathrm{Asc}(k,n-1) \cup \left\{ (\alpha', n) \mid \alpha' \in \mathrm{Asc}(k-1,n-1) \right\}$$

Thus the sum over $\alpha \in \mathrm{Asc}(k,n)$ that has been used in the definition of $s_k^{(n)}$ can be split into two parts: A sum over $\alpha \in \mathrm{Asc}(k,n-1)$ and a sum over $\alpha' \in \mathrm{Asc}(k-1,n-1)$, where we have to rebuild α as (α', n) and hence $t_{\alpha(1)} \ldots t_{\alpha(k-1)} t_n$

$$\begin{aligned} s_k^{(n)} &= \sum_{\alpha \in \mathrm{Asc}(k,n)} t_{\alpha(1)} \ldots t_{\alpha(k)} \\ &= \sum_{\alpha \in \mathrm{Asc}(k,n-1)} t_{\alpha(1)} \ldots t_{\alpha(k)} + \sum_{\alpha' \in \mathrm{Asc}(k-1,n-1)} t_{\alpha(1)} \ldots t_{\alpha(k-1)} t_n \\ &= s_k^{(n-1)} + s_{k-1}^{(n-1)} \cdot t_n \end{aligned}$$

(iii) The proof will be by induction on n, in case $n = 1$ we only have $k = 0$ and hence only need $(-1)^{n-k} s_{n-k}^{(n)} = (-1)^1 s_1^{(1)} = -t_1$. For this we get $-t_1(a_1) = -a_1$ and hence we are done. For the induction step $n \geq 2$ we will use the abbreviation $a' := (a_1, \ldots, a_{n-1})$. With this we use the induction hypothesis right away

$$\begin{aligned} & (t-a_1) \ldots (t-a_{n-1}) \, (t-a_n) \\ = \;& \left(\sum_{k=0}^{n-1} (-1)^{n-1-k} \, s_{n-1-k}^{(n-1)}(a') \, t^k \right) (t-a_n) \\ = \;& \sum_{k=0}^{n-1} (-1)^{n-1-k} \, s_{n-1-k}^{(n-1)}(a') \, t^{k+1} - \sum_{k=0}^{n-1} (-1)^{n-1-k} \, s_{n-1-k}^{(n-1)}(a') a_n \, t^k \\ = \;& \sum_{k=1}^{n} (-1)^{n-k} \, s_{n-k}^{(n-1)}(a') \, t^k + \sum_{k=0}^{n-1} (-1)^{n-k} \, s_{n-1-k}^{(n-1)}(a') a_n \, t^k \\ = \;& t^n + \sum_{k=1}^{n-1} (-1)^{n-k} \left(s_{n-k}^{(n-1)}(a') + s_{n-1-k}^{(n-1)}(\widehat{a}) a_n \right) t^k + (-1)^n s_{n-1}^{(n-1)}(a') a_n \end{aligned}$$

But $s_{n-1}^{(n-1)}(a') a_n = a_1 \ldots a_{n-1} a_n = a_1 \ldots a_n = s_n^{(n)}(a)$ is clear and by the recursion formula of (ii) we also find $s_{n-k}^{(n-1)}(a') + s_{n-1-k}^{(n-1)}(a') a_n = s_k^{(n)}(a)$. Thus we have obtained our claim

$$(t-a_1) \ldots (t-a_{n-1}) \, (t-a_n) \;=\; t^n + \sum_{k=1}^{n-1} (-1)^{n-k} \, s_k^{(n)}(a) \, t^k + (-1)^n s_n^{(n)}(a)$$

□

Proof of (7.67):

(ii) We need to show that all the coefficient polynomials $f[k] \in R[t_1, \ldots, t_{n-1}]$ are symmetric. Thus suppose we are given any permutation $\sigma \in S_{n-1}$. Then we can extend σ to S_n by letting $\sigma(n) := n$. As f is symmetric, we have $\sigma f = f$ by assumption. And as $f \mapsto \sigma f$ is a homomorphism also

$$f \;=\; \sigma f \;=\; \sigma f[0] + \sigma f[1] \, t_n + \cdots + \sigma f[d] \, t_n^d$$

Let $S := R[t_1,\dots,t_{n-1}]$, then $\{\, t_n^k \mid k \in \mathbb{N} \,\}$ is an S-basis of $S[t_n]$. Thus the above linear combination is a basis representation of f. Comparing coefficients with $f = f[0] + f[1]t_n + \cdots + f[d]t^d$ we find $f[k] = \sigma f[k]$. And as this is true for any $\sigma \in S_{n-1}$ this means that $f[k]$ is symmetric.

(iii) We will first check that $g(s_1,\dots,s_n) = 0$ implies $g = 0$, for any polynomial $g \in R[t_1,\dots,t_n]$. To do this write g in the form $g = g[0] + g[1]\,t_n + \cdots + g[d]\,t_n^d$, as in (ii). Now suppose the implication was false, i.e. there is some n and some $0 \neq g \in R[t_1,\dots,t_n]$ such that $g(s_1,\dots,s_n) = 0$. Then we choose n to be the minimal number of variables for which such a counterexample g exists. And we choose g in such a way that the t_n-degree d of g is minimal, too. In particular $g[0] \neq 0$, as we else could scratch one t_n, as this is a monic polynomial. In the case $n = 1$ we have $s_1 = t_1$ such that $0 = g(s_1) = g(t_1)$ is $g = 0$. Thus the counterexample must feature $n \geq 2$.

Let $r_k(t_1,\dots,t_{n-1}) := s_k(t_1,\dots,t_{n-1},0) \in R[t_1,\dots,t_{n-1}]$, then $r_n = 0$ and $r_k = s_k^{(n-1)}$ is the k-th elementary symmetric polynomial in $n-1$ variables, for $1 \leq k < n$, according to (7.66.(ii)). And as $g(s_1,\dots,s_n) = 0 \in R[t_1,\dots,t_n]$ we find in particular

$$g(r_1,\dots,r_{n-1},0) \;=\; g(s_1,\dots,s_n)(t_1,\dots,t_{n-1},0) \;=\; 0 \;\in\; R[t_1,\dots,t_{n-1}]$$

Now recall that we have written g as an element of $R[t_1,\dots,t_{n-1}][t_n]$, then we find $g(s_1,\dots,s_n) = g[0](s_1,\dots,s_{n-1}) + \cdots + g[d](s_1,\dots,s_{n-1})\,s_n^d$. And if we insert $(t_1,\dots,t_{n-1},0)$ into this expression, we end up with

$$0 \;=\; g(r_1,\dots,r_{n-1},0) \;=\; g(s_1,\dots,s_n)(t_1,\dots,t_{n-1},0) \;=\; g[0](r_1,\dots,r_{n-1})$$

Recall that n was taken to be minimal with this property, but here we have found a polynomial $0 \neq g[0] \in R[t_1,\dots,t_{n-1}]$ such that $g[0](r_1,\dots,r_{n-1}) = 0$. This contradicts the minimality of n. And hence there is no counterexample - the implication is universally true.

$$g(s_1,\dots,s_n) \;=\; 0 \quad\Longrightarrow\quad g \;=\; 0$$

If now f, $g \in R[t_1,\dots,t_n]$ with $f(s_1,\dots,s_n) = g(s_1,\dots,s_n)$ then $(f-g)(s_1,\dots,s_n) = 0$ and by the above implication this yields $f - g = 0$ and hence $f = g$. The converse direction is trivial.

(i) As $\sigma 0 = 0$ and $\sigma 1 = 1$ we see that 0 and 1 are symmetric polynomials. And if $a \in R$ and f, $g \in R[t_1,\dots,t_n]$ are symmetric polynomials, then by (7.65) we also have $\sigma(af) = a\sigma f = af$ and likewise $\sigma(f+g) = \sigma f + \sigma g = f + g$ and $\sigma(f \cdot g) = \sigma f \cdot \sigma g = f \cdot g$, such that af, $f+g$ and $f \cdot g$ are symmetric, again. That is the symmetric polynomials form a subalgebra of $R[t_1,\dots,t_n]$.

Thus we only need to verify, that this algebra is truly generated by the elementary symmetric polynomials. To do this we will prove the following statement: For any symmetric polynomial $s \in R[t_1,\dots,t_n]$ there is a polynomial $g \in R[t_1,\dots,t_n]$ such that we get

$$\mathrm{wgt}(g) \;\leq\; \deg(s) \quad\text{and}\quad s \;=\; g\left(s_1^{(n)},\dots,s_n^{(n)}\right)$$

We start by induction on the number n of variables. In the case $n = 1$ we have $s_1 = t_1$ and hence we may choose $g := s$. Thus we may turn to $n \geq 2$. Then we write s (and any other polynomial of

$R[t_1,\dots,t_n]$) as an element of $R[t_1,\dots,t_{n-1}][t_n]$ once more, that is

$$s(t_1,\dots,t_n) \;=\; s[0] + s[1]\,t_n + \cdots + s[d]\,t_n^d$$

By (ii) we know that $s[0]$ is symmetric, too and hence by induction hypothesis there is a polynomial $q \in R[t_1,\dots,t_{n-1}]$ such that we get $\mathrm{wgt}(q) \le \deg(s[0]) \le \deg(s)$ and $s[0] = q(r_1,\dots,r_{n-1})$ where we abbreviated $s_k := s_k^{(n)}$ and $r_k := s_k^{(n-1)} = s_k[0]$ again.

We now start a second induction on the degree $\deg(s)$ of s. In the case $\deg(s) \le 0$ we see that s is constant and hence we may choose $g := s$. Thus we may regard $\deg(s) \ge 1$. As the symmetric polynomials form an algebra we find that

$$\widetilde{s} \;:=\; s - q(s_1,\dots,s_{n-1}) \;\in\; R[t_1,\dots,t_n]$$

is symmetric, too. By construction we have $\widetilde{s}[0] = s[0] - q(r_1,\dots,r_{n-1}) = 0$ such that t_n divides $\widetilde{s}$. And it is clear that we find an upper bound of the degree of $\widetilde{s}$ by

$$\begin{aligned}\deg(\widetilde{s}) \;&\le\; \max\{\,\deg(s),\,\deg(q(r_1,\dots,r_{n-1})\,\}\\ &\le\; \max\{\,\deg(s),\,\mathrm{wgt}(q)\,\} \;=\; \deg(s)\end{aligned}$$

But as $\widetilde{s}$ is symmetric and $t_n \mid \widetilde{s}$ we see that for any $k \in 1\dots n$ we get $t_k \mid \widetilde{s}$ and hence $s_n = t_1 \dots t_n \mid \widetilde{s}$. Let us now denote $\widetilde{s} = s_n \cdot \widehat{s}$, then we claim that $\widehat{s}$ is symmetric, too: For any $\sigma \in S_n$ we have $s_n\widehat{s} = \widetilde{s} = \sigma\widetilde{s} = (\sigma s_n)\cdot(\sigma\widehat{s}) = s_n \cdot (\sigma\widehat{s})$. As s_n is monic, this implies $\widehat{s} = \sigma\widehat{s}$ and as this is true for any $\sigma \in S_n$ we see that $\widehat{s}$ is symmetric. Now

$$\deg(\widehat{s}) \;=\; \deg(\widetilde{s}) - \deg(s_n) \;\le\; \deg(s) - n \;<\; \deg(s)$$

Thus by induction hypothesis (on $\deg(s)$) there is a symmetric polynomial $p \in R[t_1,\dots,t_n]$ such that $\mathrm{wgt}(p) \le \deg(\widehat{s}) \le \deg(s) - n$ and $\widehat{s} = p(s_1,\dots,s_n)$. Altogether we got

$$\begin{aligned} s \;&=\; \widetilde{s} + q(s_1,\dots,s_{n-1})\\ &=\; s_n\widehat{s} + q(s_1,\dots,s_{n-1})\\ &=\; s_n p(s_1,\dots,s_n) + q(s_1,\dots,s_{n-1})\\ &=\; (t_n p + q)(s_1,\dots,s_n)\end{aligned}$$

Thus $g(t_1,\dots,t_n) := t_n p(t_1,\dots,t_n) + q(t_1,\dots,t_{n-1})$ does the trick and the estimation of the weighted degree of g also remains true, as we can compute

$$\begin{aligned}\mathrm{wgt}(g) \;&\le\; \max\{\,\mathrm{wgt}(t_n p),\,\mathrm{wgt}(q)\,\}\\ &\le\; \max\{\,n + \mathrm{wgt}(p),\,\mathrm{wgt}(q)\,\} \;\le\; \deg(s)\end{aligned}$$

(iv) Using (7.66.(iii)) we can compare the coefficients of the two representations of f and thereby obtain an identity for any $k \in 1\dots n$

$$a_k \;=\; (-1)^k s_k(x_1,\dots,x_d)$$

where $s_k = s_k^{(d)}$ is the elementary symmetric polynomial of degree d of $R[t_1,\dots,t_d]$. And since s is symmetric, there is a polynomial $g \in R[t_1,\dots,t_d]$ generating s via $s = g(s_1,\dots,s_d)$. Evaluating s on the roots $x_1,\dots,x_d$ then yields

$$\begin{aligned} s(x_1,\dots,x_d) &= g(s_1(x_1,\dots,x_d),\dots,s_d(x_1,\dots,x_d)) \\ &= g(-a_1,+a_2,\dots,(-1)^d a_d) \end{aligned}$$

Thus if we define $h(t_1,\dots,t_d) := g(-t_1,+t_2,\dots,(-1)^d t_d)$ we have obviously found the polynomial whose existence has been claimed.

□

Proof of (7.68):
Let us first prove that the symmetrization of any polynomial f truly is symmetric again. That is we have to check $\varrho = f_{\text{sym}} = f_{\text{sym}}$ for any permutation $\varrho \in S_n$. The idea of course is, that $\varrho S_n = \{\, \varrho\sigma \mid \sigma \in S_n \,\} = S_n$ again, as S_n is a group. Using this it is easy to compute

$$\begin{aligned} \varrho f_{\text{sym}} &= \varrho\left(\frac{1}{n!}\sum_{\sigma\in S_n}\sigma f\right) = \frac{1}{n!}\sum_{\sigma\in S_n}\varrho\,\sigma f \\ &= \frac{1}{n!}\sum_{\pi\in\varrho S_n}\pi f = \frac{1}{n!}\sum_{\pi\in S_n}\pi f = f_{\text{sym}} \end{aligned}$$

That is f_{sym} is symmetric and in particular, if $f = f_{\text{sym}}$ then f has to be symmetric. Conversely, if f is symmetric, then $\sigma f = f$ for any $\sigma \in S_n$ hence the sum in f_{sym} consists of $\#S_n$ times f. Yet $\#S_n = n!$ such that the factor in front cancels $\#S_n$, in effect only $f_{\text{sym}} = f$ remains.

Analogously we will prove that f_{asym} is antisymmetric. That is we have to check $\varrho = f_{\text{sym}} = \text{sgn}(\varrho) f_{\text{sym}}$ for any permutation $\varrho \in S_n$. Again we use $\varrho S_n = S_n$ and also $\text{sgn}(\sigma) = \text{sgn}(\varrho)^2\text{sgn}(\sigma) = \text{sgn}(\varrho)\text{sgn}(\varrho\sigma)$ to compute

$$\begin{aligned} \varrho f_{\text{asym}} &= \varrho\left(\frac{1}{n!}\sum_{\sigma\in S_n}\text{sgn}(\sigma)\sigma f\right) = \frac{1}{n!}\sum_{\sigma\in S_n}\text{sgn}(\sigma)\varrho\,\sigma f \\ &= \frac{1}{n!}\sum_{\pi\in\varrho S_n}\text{sgn}(\sigma)\pi f = \frac{1}{n!}\sum_{\pi\in\varrho S_n}\text{sgn}(\varrho)\text{sgn}(\pi)\pi f \\ &= \text{sgn}(\varrho)\,\frac{1}{n!}\sum_{\pi\in S_n}\text{sgn}(\pi)\pi f = \text{sgn}(\varrho) f_{\text{asym}} \end{aligned}$$

That is f_{asym} is symmetric and in particular, if $f = f_{\text{asym}}$ then f has to be anti-symmetric. Conversely, if f is anti-symmetric, then $\sigma f = \text{sgn}(\sigma) f$ such that in each summand $\text{sgn}(\sigma)^2 = 1$ vanishes and the sum in f_{asym} runs over $\#S_n$ times f. Again, $\#S_n = n!$ such that the factor in front cancels $\#S_n$, in effect only $f_{\text{asym}} = f$ remains. □

Proof of (1.49):

(i) We first prove the uniqueness of c and h: Suppose the identity in the claim holds true, then

multiplying this equation with $(t-x)^k g(t)$ yields

$$cg(t) + h(t)(t-x) \;=\; f(t)$$

This is an equation in the polynomial ring $E[t]$, if we evaluate both sides in x the right-hand side is reduced to $cg(x)$, as $(t-x)(x) = 0$. Therefore $cg(x) = f(x)$ such that we get $c = f(x)g(x)^{-1}$ and thereby also $h(t) = (f(t) - cg(t))/(t-x)$ is determined uniquely. Thus it only remains to prove that such c and h truly exist. If we define $c := f(x)g(x)^{-1} \in E$ then it is clear that

$$\Big(f(t) - cg(t)\Big)(x) \;=\; 0$$

And as x is a root of $f(t) - cg(t)$ by (7.54.(iii)) $t - x$ is a divisor, that is there is a polynomial $h \in E[t]$ such that $h(t)(t-x) = f(t) - cg(t)$. And if we divide this equality by $(t-x)^k g(t)$ in $E(t)$ then we get the equality (almost) as in the claim

$$\frac{h(t)}{(t-x)^{k-1}g(t)} \;=\; \frac{f(t) - cg(t)}{(t-x)^k g(t)} \;=\; \frac{f(t)}{(t-x)^k} - \frac{cg(t)}{(t-x)^k g(t)}$$

(ii) We obviously use induction on the number r of distinct roots of g. In the case $r = 1$ we use a second induction on $k = k_1$. In the case $k = 1$ we have $g = b(t-x)$ and since $\deg(f) < \deg(g) = 1$ we see that f is constant $c = f \in E$ already - thus $f(t)/g(t) = c/b(t-x)$ is established. Now consider the induction step $k \mapsto k+1$, here we apply (i) with $g(t) = b$ to get

$$\frac{f(t)}{g(t)} \;=\; \frac{f(t)}{(t-x)^{k+1}b} \;=\; \frac{c}{(t-x)^{k+1}} + \frac{h(t)}{(t-x)^k b}$$

Hereby $c = f(x)g(x)^{-1} = f(x)b^{-1}$ and $h(t) = (f(t) - cb)/(t-x)$. From the explicit description of h we get $\deg(h) = \deg(f) - 1 < \deg(g) - 1 = k$. Thus we may apply the induction hypothesis to $h(t)/b(t-x)^k$ obtaining the claim in the case $r = 1$:

$$\frac{f(t)}{g(t)} \;=\; \frac{c}{(t-x)^{k+1}} + \frac{h(t)}{b(t-x)^k} \;=\; \frac{c}{(t-x)^{k+1}} + \sum_{j=1}^{k} \frac{c_j}{(t-x)^j}$$

So we are now concerned with the induction step $r \mapsto r+1$: To do this we abbreviate $k := k_{r+1}$ and $x := x_{r+1}$ and let $q(t) := b(t-x_1)^{k_1} \dots (t-x_r)^{k_r}$. Then g can be written as $g(t) = (t-x)^k q(t)$ and $q(x) \neq 0$, so we are in the position to apply (i) again, this time with $g(t) = q(t)$

$$\frac{f(t)}{g(t)} \;=\; \frac{f(t)}{(t-x)^k q(t)} \;=\; \frac{c}{(t-x)^k} + \frac{h(t)}{(t-x)^{k-1}q(t)}$$

Thereby $c = f(x)q(x)^{-1}$ again and $h(t)$ is given to be $h(t) = (f(t) - cq(t))/(t-x)$ and as both $\deg(q) = \deg(g) - k < \deg(g)$ and $\deg(f) < \deg(g)$ we find $\deg(f(t) - cq(t)) < \deg(g)$ and hence

$$\deg(h) \;<\; \deg(g) - 1 \;=\; \deg\Big((t-x)^{k-1}q\Big)$$

Hence the induction hypothesis may be applied to $h(t)/(t-x)^{k-1}q(t)$ again such that we can also

conclude this induction step, by replacing $h(t)$

$$\frac{f(t)}{g(t)} \;=\; \frac{c}{(t-x)^k} + \sum_{i=1}^{r}\sum_{j=1}^{k_i}\frac{c_{i,j}}{(t-x_i)^j} + \sum_{j=1}^{k-1}\frac{c_{r+1,j}}{(t-x)^j}$$

□

Proof of (7.23):

(i) Consider any polynomial $f \in R[t_i \mid i \in I]$, by definition f only has finitely many non-zero coefficients $f[\alpha] \neq 0$, where $\alpha = (\alpha_i) \in \mathbb{N}^{\oplus I}$. Likewise any α only has finitely many non-zero entries. That is $I(\alpha) := \{\, i \in I \mid \alpha_i \neq 0 \,\} \in \Omega(I)$ is a finite set and as

$$I(f) \;\subseteq\; \bigcup \Big\{\, I(\alpha) \mid \alpha \in \mathbb{N}^{\oplus I}, f[\alpha] \neq 0 \,\Big\}$$

is a finite union of finite sets, we see that $I(f) \in \Omega(I)$ is a finite set. Also, for any α with $f[\alpha] \neq 0$, we get $I(\alpha) \subseteq I(f)$. But from this it is clear, that f is contained in R_ω, where $\omega := I(f)$, as

$$f \;=\; \sum_{\alpha\in\mathbb{N}^{\oplus I}} f[\alpha]\, t^\alpha \;=\; \sum_{\alpha\in I(f) f[\alpha]\, \prod_{i\in I(\alpha)}} t_i^{\alpha_i} \;\in\; R[t_i \mid i \in I(f)]$$

As f was an arbitrary polynomial, we see that the entire polynomial ring is contained in the union of the finitely generated polynomial rings $R[t_i \mid i \in \omega]$.

(ii) By construction of polynomial rings $R[t_1,\ldots,t_n]$ has the basis $\{\, t^\alpha \mid \alpha \in \mathbb{N}^n \,\}$ as an R-module. And for some $f \in R[t_1,\ldots,t_n]$ the inclusion $f \in R[t_1,\ldots,t_j]$ means that

$$\forall\, \alpha = (\alpha_1,\ldots,\alpha_n) \in \mathbb{N} \;:\; \big(\exists\, k \in j+1\ldots n \;:\; \alpha_k > 0 \;\Longrightarrow\; f[\alpha] = 0\big)$$

Likewise $f \in R[t_i,\ldots,t_n]$ means $f[\alpha] = 0$ for any $\alpha \in \mathbb{N}^n$ that features some $k \in 1\ldots i-1$ whith $\alpha_k > 0$. Now take a look at any $f \in R[t_1,\ldots,t_n]$ in this basis representation

$$f \;=\; \sum_{\alpha\in\mathbb{N}^n} f[\alpha]\, t^\alpha$$

If $f \in R[t_1,\ldots,t_j] \cap R[t_i,\ldots,t_n]$ then we can omit all $\alpha = (\alpha_1,\ldots,\alpha_n) \in \mathbb{N}^n$ with $\alpha_k > 0$ for some $k \in \{\, 1,\ldots,i-1,j,\ldots,n \,\}$. That is there only remain those $f[\alpha]$ that belong to some α for which we get $\alpha_k > 0 \;\Longrightarrow\; k \in i\ldots j$. And then f clearly is an element of

$$f \;=\; \sum_{(\alpha_i,\ldots,\alpha_j)\in\mathbb{N}^{j-i+1}} f[\alpha]\, t^\alpha \;\in\; R[t_i,\ldots,t_j]$$

By the same reasoning such an f is contained in the intersection $R[t_1,\ldots,t_j] \cap R[t_i,\ldots,t_n]$. In particular, if $j < i$ then $i\ldots j = \emptyset$. That is the only $\alpha \in \mathbb{N}^n$ for which $f[\alpha] \neq 0$ is allowed is $\alpha = 0$. And this means $f = f[\alpha]\,\mathbf{1} \in R$ is a constant polynomial (and vice versa).

(iii) It is obvious that ε is surjective, additive $\varepsilon(f+g) = \varepsilon(f) + \varepsilon(g)$, linear $\varepsilon(a\,f) = a\,\varepsilon(f)$ and unital $\varepsilon(\mathbf{1}) = 1$. The only non-obvious part is the multiplicativity, thus let $f, g \in R[\![t_i \mid i \in I]\!]$ and

compute

$$\begin{aligned}\varepsilon(f\,g) &= \varepsilon\left(\sum_{\gamma}\sum_{\alpha+\beta=\gamma} f[\alpha]\,g[\beta]\,t^{\gamma}\right)\\ &= \sum_{\alpha+\beta=0} f[\alpha]\,g[\beta] \;=\; f[0]\,g[0] \;=\; \varepsilon(f)\,\varepsilon(g)\end{aligned}$$

(iv) Clearly $\mathbb{N}^{n+1} = \mathbb{N}^n \times \mathbb{N}$ is a product of the commutative monoids $\mathbb{N}^n$ and $\mathbb{N}$. Therefore the claim is just a special case of (7.12.(vi)).

(iv) Clearly Φ_a is bijective, as the inverse mapping is given by $\Phi_a^{-1} = \Phi_{-a}$. Further it is obvious that Φ_a is additive $\Phi_a(f+g) = \Phi_a(f) + \Phi_a(g)$, linear $\Phi_a(\lambda\, f) = \lambda\, \Phi_a(f)$ and unital $\Phi_a(\mathbf{1}) = \mathbf{1}$. Thus it only remains to verify the multiplicativety of Φ_a. Choose any $f, g \in R[t_1, \ldots, t_n]$ and compute

$$\begin{aligned}\Phi_a(f\,g) &= \Phi_a\left(\sum_{\gamma}\sum_{\alpha+\beta=\gamma} f[\alpha]\,g[\beta]\,t^{\gamma}\right)\\ &= \sum_{\gamma}\sum_{\alpha+\beta=\gamma} f[\alpha]\,g[\beta]\,(t+a)^{\gamma}\\ &= \left(\sum_{\alpha} f[\alpha]\,(t+a)^{\alpha}\right)\left(\sum_{\beta} g[\beta]\,(t+a)^{\beta}\right)\\ &= \Phi_a(f)\,\Phi_a(g)\end{aligned}$$

(vi) We will prove this by induction on n: For the case $n = 1$ we use division with remainder (2.67) of f by $t_1 - a_1$ to write f in the form $f(t_1) = q(t_1)(t_1 - a_1) + r(t_1)$. Thereby $r = 0$ or $\deg(r) < \deg(t_1 - a_1) = 1$ such that $\deg(r) = 0$. That is $r(t_1) = r\mathbf{1}$ for some $r \in R$, possibly $r = 0$. Let us now evaluate $f(t_1)$ in a_1 here we find

$$f(a_1) \;=\; q(a_1)(a_1 - a_1) + r(a_1) \;=\; q(a_1)\cdot 0 + r \;=\; r$$

That is we have $f(t_1) = q(t_1)(t_1 - a_1) + r = q(t_1)(t_1 - a_1) + f(a_1)$ and this is precisely the claim in the case $n = 1$. For the induction step we consider $f \in R[t_1, \ldots, t_n, t_{n+1}]$ and let $S := R[t_1, \ldots, t_n]$. By the isomprphism in (iii) we may write $f(t_1, \ldots, t_n, t_{n+1}) \in S[t_{n+1}]$. Let us now consider any $a_{n+1} \in R \subseteq S$. As in the case $n = 1$ we may write

$$f(t_1, \ldots, t_n, t_{n+1}) \;=\; q_{n+1}(t_1, \ldots, t_n, t_{n+1})\big(t_{n+1} - a_{n+1}\big) + f(t_1, \ldots, t_n, a_{n+1})$$

for some $q_{n+1} \in S[t_{n+1}] = R[t_1, \ldots, t_n, t_{n+1}]$. However we clearly have $f(t_1, \ldots, t_n, a_{n+1}) \in S$ and hence we may use the induction hypothesis to write this polynomial in the form

$$f(t_1, \ldots, t_n, a_{n+1}) \;=\; \sum_{k=1}^{n} q_k(t_1, \ldots, t_k)\big(t_k - a_k\big) + f(a_1, \ldots, a_n, a_{n+1})$$

If we combine these two equations, the equation of the induction step becomes readily apparent, so we may conclude our proof of (v) with the following equations

$$f(t_1, \ldots, t_n, t_{n+1}) \;=\; q_{n+1}(t_1, \ldots, t_n, t_{n+1})\big(t_{n+1} - a_{n+1}\big)$$

$$
\begin{aligned}
&\quad + \sum_{k=1}^{n} q_k(t_1,\dots,t_k)\big(t_k - a_k\big) + f(a_1,\dots,a_n,a_{n+1}) \\
&= \sum_{k=1}^{n+1} q_k(t_1,\dots,t_k)\big(t_k - a_k\big) + f(a_1,\dots,a_n,a_{n+1})
\end{aligned}
$$

(vii) Because of the isomorphism in (iv) it suffices to check the case $n = 1$. If now $a \in R^*$ is a unit of R it is clear that $a\mathbf{1} \in R[t]^*$ is a unit of $R[t]$, since $(a\mathbf{1})^{-1} = a^{-1}\mathbf{1}$. In the converse direction we fix the standard order $\leq$ on $\mathbb{N}$ which clearly is a monomial well-ordering. If now $f \in R[t]^*$ is a unit of $R[t]$ then by definition there is some $g \in R[t]$ such that $fg = \mathbf{1}$. Thus we may evaluate the degrees to find that

$$
0 \;=\; \deg(\mathbf{1}) \;=\; \deg(f\,g) \;=\; \deg(f) + \deg(g)
$$

This of course implies $\deg(f) = 0 = \deg(g)$, i.e. f and g are constant polynomials $f = a\mathbf{1}$ and $g = b\mathbf{1}$. But now it is obvious that $b = a^{-1}$ and hence a truly is an invertible element of R.

(viii) Because of isomorphism in (iv) it suffices to check the case $n = 1$ again. We first assume that $f \in R[\![t]\!]^*$ is an invertible element of $R[\![t]\!]$. By definition this means that there is some $g \in R[\![t]\!]$ such that $fg = \mathbf{1}$. We now apply the epimorphism in (ii) to find that $f[0]$ truly is an invertible element of R

$$
1 \;=\; \varepsilon(\mathbf{1}) \;=\; \varepsilon(f\,g) \;=\; \varepsilon(f)\,\varepsilon(g) \;=\; f[0]\,g[0]
$$

In the converse direction we define g as in the remark above, i.e. we let $g[0] := f[0]^{-1}$ and recursively $g[k] := -f[0]^{-1} \sum_{i=0}^{k-1} f[n-i]\,g[i]$. By the construction it is clear that $fg[0] = f[0]g[0] = 1$. We will now prove that $fg = \mathbf{1}$, i.e. $fg[k] = 0$ for any $k \in \mathbb{N}$. To do this we use induction on k and compute

$$
\begin{aligned}
fg[1] &= f[0]\,g[1] + f[1]\,g[0] \\
&= -f[1]\,g[0] + f[1]\,g[0] \;=\; 0 \\
fg[k] &= \sum_{i=0}^{k} f[k-i]\,g[i] \\
&= \sum_{i=0}^{k-1} f[k-i]\,g[i] + f[0]\,g[k] \\
&= \sum_{i=0}^{k-1} f[k-i]\,g[i] - \sum_{i=0}^{k-1} f[k-i]\,g[i] \;=\; 0
\end{aligned}
$$

□

Proof of (7.18):

The proofs of all these statements are straightforward computations. The statements for the sum $f+g$ are simple and the proofs of the statements for the product fg follow the same lines as the proof of $R[t \mid A]$ being an integral domain. Thus we introduce the following notation again: Consider $0 \neq f, g \in R[t \mid A]$ any two non-zero polynomials and denote the coefficients on which f and g are non-zero by

$$
\{\,\alpha_1,\dots,\alpha_m\,\} \;:=\; \{\,\alpha \in A \mid f[\alpha] \neq 0\,\}
$$

$$\{\,\beta_1,\ldots,\beta_n\,\} \;:=\; \{\,\beta\in A \mid g[\beta]\neq 0\,\}$$

Without loss of generality we may assume $\alpha_1<\cdots<\alpha_m$ and likewise $\beta_1<\cdots<\beta_n$. Then this will enable us to prove the above assertions (for a general commutative ring R) easily:

- By definition we immediately get $\mathrm{lt}(f)=f[\alpha_m]\,t^{\alpha_m}=\mathrm{lc}(f)\,\mathrm{lm}(f)$.
- If $\max\{\,\alpha_m,\beta_n\,\}<\gamma$ then $f[\gamma]=0=g[\gamma]$ and hence $f[\gamma]+g[\gamma]=0$ as well. But this already proves $\deg(f+g)\leq\max\{\,\deg(f),\deg(g)\,\}$.
- If $\alpha_m+\beta_n<\gamma$ then for any $i\in 1\ldots m$ and $j\in 1\ldots n$ we obtain $\alpha_i+\beta_j\leq\alpha_m+\beta_j\leq\alpha_m+\beta_n<\gamma$. Hence there are no non-zero coefficients $f[\alpha_i]\neq 0$ and $g[\beta_j]\neq 0$ such that $\alpha_i+\beta_j=\gamma$. But for the coefficient $fg\,[\gamma]$ of the product fg this implies $fg[\gamma]=0$, as at least one $f[\alpha_i]$ or $g[\beta_j]$ has to be 0. And hence $\deg(f\cdot g)\leq\deg(f)+\deg(g)$, as

$$fg[\gamma] \;=\; \sum_{\alpha+\beta=\gamma} f[\alpha_i]\,g[\beta] \;=\; \sum_{\alpha_i+\beta_j=\gamma} f[\alpha_i]\,g[\beta_j] \;=\; 0$$

In the following we assume that R is an integral domain and A is integral, too. As $\leq$ is a positive order on A and A is integral $(A,+,\leq)$ is a strictly positively ordered monoid, by (7.6.(iii)). Then we are able to prove the even stronger statements:

- Let $\gamma:=\alpha_m+\beta_n$, then for any $i\in 1\ldots m$ and $j\in 1\ldots n$ we find that $\alpha_i+\beta_j=\gamma$ is equivalent, to $i=m$ and $j=n$, due to (7.6.(iv)). But for the coefficient $fg\,[\gamma]$ of the product fg this again implies

$$\sum_{\alpha+\beta=\gamma} f[\alpha_i]\,g[\beta] \;=\; \sum_{\alpha_i+\beta_j=\gamma} f[\alpha_i]\,g[\beta_j] \;=\; f[\alpha_m]\,g[\beta_n]$$

 But as R is an integral domain, we conclude that $f[\alpha_m]\,g[\beta_n]\neq 0$ is non-zero again and therefore $\deg(f\cdot g)\geq\deg(f)+\deg(g)$. But as $\deg(f\cdot g)\leq\deg(f)+\deg(g)$ is true in general, we conclude that $f[\alpha_m]\,g[\beta_n]\neq 0$ implies $\deg(f\cdot g)=\deg(f)+\deg(g)$.
- As we have seen $\gamma:=\deg(f\cdot g)=\deg(f)+\deg(g)=\alpha_m+\beta_n$ we immediately get $\mathrm{lm}(f\cdot g)=t^{\gamma}=t^{\alpha_m+\beta_n}=t^{\alpha_m}\cdot t^{\beta_n}=\mathrm{lt}(f)\cdot\mathrm{lt}(g)$ and likewise $\mathrm{lc}(f\cdot g)=fg\,[\gamma]=f[\alpha_m]\,g[\beta_n]=\mathrm{lc}(f)\cdot\mathrm{lc}(g)$. But of course this includes $\mathrm{lt}(f\cdot g)=\mathrm{lt}(f)\cdot\mathrm{lt}(g)$, as this is immediate from $\mathrm{lt}(f\cdot g)=\mathrm{lc}(f\cdot g)\,\mathrm{lm}(f\cdot g)=\mathrm{lc}(f)\cdot\mathrm{lc}(g)\,\mathrm{lm}(f)\cdot\mathrm{lm}(g)=\mathrm{lc}(f)\,\mathrm{lm}(f)\cdot\mathrm{lc}(g)\,\mathrm{lm}(g)=\mathrm{lt}(f)\cdot\mathrm{lt}(g)$.
- Nota even if R is no integral domain, but f is monic we have $f[\alpha_m]=1$ and hence $f[\alpha_m]\,g[\beta_n]=g[\beta_n]\neq 0$. Analogously the same is true, if g is monic. But from this we found $\deg(f\cdot g)=\deg(f)+\deg(g)$. And from this property all the following three identities were inferred.

□

Proof of (7.26):

(i) If $a=0$, then $at^{\alpha}=0$ is the zero-polynomial and hence $\deg_\omega(0)=-\infty$ by definition. And if $a\neq 0$ then the only (and hence maximal) $\beta\in\mathbb{N}^n$ with $at^{\alpha}[\beta]\neq 0$ is $\beta=\alpha$ such that $\deg_\omega(at^{\alpha})=|\alpha|_\omega$.

(ii) Consider any non-zero polynomial $0\neq f\in R[t_1,\ldots,t_n]$ then compute

$$\deg_\omega(f) \;=\; \max\{\,|\alpha|_\omega \mid \alpha\in\mathbb{N}^n, f[\alpha]\neq 0\,\}$$

$$\begin{aligned} &= \max\{\, \deg_\omega(f[\alpha]t^\alpha) \mid \alpha \in \mathbb{N}^n, f[\alpha] \neq 0 \,\} \\ &= \max\{\, \deg_\omega(f[\alpha]t^\alpha) \mid \alpha \in \mathbb{N}^n \,\} \end{aligned}$$

(iii) and (iv) can be treated simultaneously. We fix the ω-graded lexicographic order on $\mathbb{N}^n$ and denote it by $\leq := \leq_{\text{lex}}$. Then we already know that $(\mathbb{N}^n, +, \leq)$ is a positively (even algebraically) ordered monoid and by construction of $\leq$ for any polynomial $f \in R[t_1, \ldots, t_n]$

$$\begin{aligned} \deg_\omega(f) &= \max\{\, |\alpha|_\omega \mid f[\alpha] \neq 0 \,\} \\ &= |\max_{\leq}\{\, \alpha \mid f[\alpha] \neq 0 \,\}|_\omega \\ &= |\deg_{\leq}(f)|_\omega \end{aligned}$$

But for $\deg_{\leq}$ the claims have already been proved in (7.18) and hence we get

$$\begin{aligned} \deg_\omega(f+g) &= |\deg_{\leq}(f+g)|_\omega \\ &\leq |\max_{\leq}\{\, \deg_{\leq}(f), \deg_{\leq}(g) \,\}|_\omega \\ &= \max\{\, |\deg_{\leq}(f)|_\omega, |\deg_{\leq}(g)|_\omega \,\} \\ &= \max\{\, \deg_\omega(f), \deg_\omega(g) \,\} \end{aligned}$$

$$\begin{aligned} \deg_\omega(f \cdot g) &= |\deg_{\leq}(f \cdot g)|_\omega \\ &\leq |\deg_{\leq}(f) + \deg_{\leq}(g)|_\omega \\ &= |\deg_{\leq}(f)|_\omega + |\deg_{\leq}(g)|_\omega \\ &= \deg_\omega(f) + \deg_\omega(g) \end{aligned}$$

□

Proof of (7.22):
Let us abbreviate $A := R[t_i \mid i \in I]$ and $B := R[t_j \mid j \in J]$. The embedding $A \hookrightarrow B$ has already been proved in (7.12.(iii)). In particular if f and $g \in A$, then $fg \in A$ again. Conversely consider $0 \neq f, g \in B$ such that $fg \in A$. For any $j \in J$ let us define

$$\deg_j(f) := \begin{cases} \max\{\, \alpha_j \mid \alpha \in \mathbb{N}^{\oplus J},\, f[\alpha] \neq 0 \,\} & \text{for } f \neq 0 \\ -\infty & \text{for } f = 0 \end{cases}$$

Note that this is the degree in the polynomial ring $S[t_j]$ where S denotes the integral domain $S := R[t_i \mid i \in J \setminus j]$. This is legitimate, since $B \cong_{\mathsf{a}} S[t_j]$ according to (7.12.(vi)) - you may also want to compare (7.23.(iii)). Then by construction of the embedding we have $f \in R[t_i \mid i \in I]$ if and only if $\deg_j(f) = 0$ for any $j \in J \setminus I$. And as S is an integral domain we have

$$0 = \deg_j(fg) = \deg_j(f) + \deg_j(g)$$

for any $j \in J \setminus I$. As both $\deg_j(f)$ and $\deg_j(g) \in \mathbb{N}$ their sum can only be zero, if $\deg_j(f) = 0 = \deg_j(g)$ such that f and $g \in A$. □

Proof of (7.28):
Let us prove the claim by induction on n: In case $n = 1$ we are given a polynomial $f \in R[t_1]$, let $d := \deg(f)$ be its degree, then we can write f in the following form

$$f \;=\; \sum_{i=0}^{d} f[i]\, t_1^i \;=\; f(0) + \sum_{i=1}^{d} f[i]\, t_1^i \;=\; f(0) + t_i \sum_{i=0}^{d-1} f[i+1]\, t_1^i$$

That is we may take $f_1 = \sum_i f[i+1] t_1^i$ which is a polynomial in $R[t_1]$ of degree $\deg(f_1) = d - 1 < d = \deg(f)$. So we can commence with the induction step $n+1$: That is we are given a polynomial $f \in R[t_1, \ldots, t_{n+1}]$ and let $d := \deg_{n+1}(f)$. We can then we write f, as

$$f \;=\; \sum_{\alpha \in \mathbb{N}^n} \sum_{i=0}^{d} f[\alpha, i]\, t^\alpha t_{n+1}^i$$

Let us split this sum into a part with $i = \alpha_{n+1} = 0$ and a part with $i = \alpha_{n+1} \geq 1$. Then we can pull out t_{n+1} once (as above) to arrive at the following expression

$$f \;=\; \sum_{\alpha \in \mathbb{N}^n} f[\alpha, 0]\, t^\alpha + \left(\sum_{i=0}^{d-1} f[\alpha, i+1]\, t^\alpha t_{n+1}^i \right) t_{n+1}$$

The term in brackets is $f_{n+1} \in R[t_1, \ldots, t_{n+1}]$. From its explicit representation we find $\deg(f_{n+1}) = \deg(f) - 1 < \deg(f)$ again. That is f_{n+1} satisfies properties (1) and (2) of the claim. And the term in front is a polynomial in $R[t_1, \ldots, t_n]$ only. Thus by induction hypothesis it is of the form $f(0) + \sum_k f_k(t_1, \ldots, t_k) t_k$ for some polynomials f_k satisfying properties (1) and (2). Altogether we have found

$$f \;=\; f(0) + \sum_{k=1}^{n} f_k(t_1, \ldots, t_k) t_k + f_{n+1}(t_1, \ldots, t_{n+1}) t_{n+1}$$

Thus $f \in R[t_1, \ldots, t_{n+1}]$ can be written in the form given in the claim, again. And as all the f_k for $k \in 1 \ldots n+1$ satisfy the properties (1) and (2) we have completed the induction step. □

Proof of (3.43):

(i) If $f \in \mathfrak{a}R[t]$ then by (3.40.(i)) f is of the form $f = a_1 f_1 + \cdots + a_n f_n$ for some $a_i \in \mathfrak{a}$ and $f_i \in R[t]$. Thereby for any $k \in \mathbb{N}$ the k-th coefficient of f is given to be $f[k] = a_1 f_1[k] + \cdots + a_n f_n[k] \in \mathfrak{a}$ and hence $f \in \mathfrak{a}[t]$. Conversely if $f \in \mathfrak{a}[t]$ is of degree $d := \deg(f)$, then f is also is in $\mathfrak{a}R[t]$, as

$$f \;=\; \sum_{k=0}^{d} f[k] t^k \;\in\; \sum_{k=0}^{d} \mathfrak{a}R[t] \;=\; \mathfrak{a}R[t]$$

(ii) Clearly we obtain a surjective homomorphism of rings by extension of the canonical epimorphism $R \twoheadrightarrow R/\mathfrak{a} : b \mapsto b + \mathfrak{a}$ to the polynomial ring. That is we regard

$$\varrho \;:\; R[t] \;\twoheadrightarrow\; \left(R \Big/ \mathfrak{a} \right)[t] \;:\; f \mapsto \sum_{k=0}^{\infty} \big(f[k] + \mathfrak{a} \big) t^k$$

We now prove, that the kernel of ϱ is given to be $\mathrm{kn}(\varrho) = \mathfrak{a}[t]$. Then the isomorphism follows from the first isomorphism theorem (1.83.(ii)). If $f \in \mathfrak{a}[t]$ then $f[k] \in \mathfrak{a}$, such that $f[k] + \mathfrak{a} = 0 + \mathfrak{a}$ for

any $k \in \mathbb{N}$ and thereby $\varrho(f) = 0$. Conversely consider some $f \in R[t]$ with $\varrho(f) = 0$. That is $\varrho(f)[k] = 0$ for any $k \in \mathbb{N}$. But by definition of ϱ this is $f[k] + \mathfrak{a} = 0 + \mathfrak{a}$ and hence $f[k] \in \mathfrak{a}$. And this again means $f \in \mathfrak{a}[t]$.

- Clearly $\mathfrak{a}[t] + tR[t]$ is an ideal, as it is a sum of such. We have to check, that this is identical, to $\{ f \in R[t] \mid f(0) \in \mathfrak{a} \}$. Let us begin with some $f \in R[t]$ with $a := f(0) \in \mathfrak{a}$. That is f is of the form $f = a\mathbf{1} + tg(t)$ where $g := f[1] + f[2]t + \cdots \in R[t]$. In this form we see $f \in \mathfrak{a}[t] + tR[t]$ clearly. Conversely, if $g \in \mathfrak{a}[t] + tR[t]$ then $g = f + th$ for some $f \in \mathfrak{a}[t]$ and $h \in R[t]$. From this we see $g(0) = f(0) + 0 \cdot h(0) = f(0) = f[0] \in \mathfrak{a}$. Thus both descriptions of this ideal are identical.

- Much like the proof of the first part we start with a homomorphism of rings, that obviously is surjective: $\varrho : R[t] \to R/\mathfrak{a} : f \mapsto f(0) + \mathfrak{a}$. This time we need to show $\ker(\varrho) = \mathfrak{a}[t] + tR[t]$. If we start with $f \in R[t]$ with $0 = \varrho(f) = f(0) + \mathfrak{a}$ we see $f(0) \in \mathfrak{a}$. But then

$$f \;=\; \sum_{k=0}^{\infty} f[k]t^k \;=\; f(0) + t\sum_{k=1}^{\infty} f[k]t^{k-1} \;\in\; \mathfrak{a} + tR[t]$$

and in particular $f \in \mathfrak{a}[t] + tR[t]$. If we conversely start with $f \in \mathfrak{a}[t] + tR[t]$, then f is of the form $f = \sum_k a_k t^k + tg(t)$ for some $a_k \in \mathfrak{a}$ and $g \in R[t]$. In particular $f(0) = a_0 \in \mathfrak{a}$ and hence $\varrho(f) = 0$. That is we have both inclusions of $\ker(\varrho) = \mathfrak{a}[t] + tR[t]$ and hence we find the isomorphism in the claim by the first isomorphism theorem (1.83.(ii)), again.

(iii) If $\mathfrak{p}$ is prime then $R/\mathfrak{p}$ is an integral domain and hence the polynomial ring $(R/\mathfrak{p})[t]$ is an integral domain, too. By the first isomorphism in (ii) this means $R[t]/\mathfrak{p}[t]$ is an integral domain, as well. And this means $\mathfrak{p}[t] \trianglelefteq_{\mathrm{i}} R[t]$ is a prime ideal, by (2.12). In complete analogy: If $\mathfrak{m}$ is a maximal ideal, then $R/\mathfrak{m}$ is a field. And due to the second isomorphism in (ii) we find that $R[t]/\widetilde{\mathfrak{m}}$ is a field. And this again means, that $\widetilde{\mathfrak{m}}$ is a maximal ideal of $R[t]$.

□

Proof of (2.168):

(i) By (3.43.(i)) we have $\mathfrak{m}[t] = \mathfrak{m}\,R[t]$ and (8.15) guarantees $\mathfrak{m}\,R[t] = (\mathfrak{n} \cap R)R[t] \subseteq \mathfrak{n}$. As $\mathfrak{n}$ is a maximal ideal, by assumption we find that

$$\mathfrak{n} \Big/ \mathfrak{m}[t] \;\trianglelefteq_{\mathrm{i}}\; R[t] \Big/ \mathfrak{m}[t] \;\cong_{\mathrm{r}}\; \left(R \Big/ \mathfrak{m}\right)[t]$$

is a maximal ideal, again - where the isomorphy is due to (3.43.(ii)). By assumption $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ is a maximal ideal and hence $E := R/\mathfrak{m}$ is a field. Then the polynomial ring $E[t]$ is a PID. Thus the image of $\mathfrak{n}/\mathfrak{m}[t]$ in $E[t]$ is a maximal ideal again and hence generated by a non-zero prime element $\overline{f} \in E[t]$. We can even choose $\overline{f}$ to be monic. The isomorphism is given to be

$$\Phi\big(f + \mathfrak{m}[t]\big) \;=\; \sum_{k=0}^{\infty} \big(f[k] + \mathfrak{m}\big)\, t^k$$

Pick up some $f \in R[t]$ such that $\Phi(f + \mathfrak{m}[t]) = \overline{f}$. As $\overline{f}$ is monic, so is f and as $\overline{f}$ is a prime

element, so is $f+\mathfrak{m}[t]$. Let us evaluate $\mathfrak{n}/\mathfrak{m}[t]$, which is the pre-image of $\overline{f}E[t]$ under Φ

$$\mathfrak{n}\Big/_{\mathfrak{m}[t]} \;=\; \Phi^{-1}\left(\overline{f}\,E[t]\right) \;=\; \big(f+\mathfrak{m}[t]\big)^{R[t]}\Big/_{\mathfrak{m}[t]} \;=\; \mathfrak{m}[t]+fR[t]\Big/_{\mathfrak{m}[t]}$$

By the correspondence theorem of ideals in quotient rings we now see that $\mathfrak{n}$ corresponds to the ideal $\mathfrak{m}[t]+fR[t]$. This is property (1) and we have already argued above, that f is monic and (2) $f+\mathfrak{m}[t]$ is a prime element.

(ii) Let $U := R\setminus\{0\}$, that is $E = U^{-1}R$ and thereby $U^{-1}R[t] := (U^{-1}R)[t] = E[t]$. By (2.132.(i)) we have an isomorphism $\Phi : U^{-1}R[t] \xrightarrow{\sim} E[t]$ given by $\Phi(f/u) = \sum_k (f[k]/u)\,t^k$. An isomorphism of rings obviously induces a one-to-one correspondence of prime ideals

$$\begin{array}{ccc} \mathrm{Spec}\big(U^{-1}R[t]\big) & \longleftrightarrow & \mathrm{Spec}\big(E[t]\big) \\ \mathfrak{v} & \mapsto & \Phi\big(\mathfrak{v}\big) \end{array}$$

And by the correspondence theorem of ideals in localisations (2.129) the spectrum of $U^{-1}R[t]$ corresponds to the set of prime ideals $\mathfrak{p}$ of $R[t]$ such that $\mathfrak{p}\cap U = \emptyset$. As $U = R\setminus\{0\}$ the latter property can be put as $\mathfrak{p}\cap R = 0$, equivalently. Thus we have found another correspondence

$$\begin{array}{ccc} \mathrm{Spec}\big(U^{-1}R[t]\big) & \longleftrightarrow & \big\{\,\mathfrak{p}\in\mathrm{Spec}\big(R[t]\big)\mid \mathfrak{p}\cap R = 0\,\big\} \\ \mathfrak{u} & \mapsto & \mathfrak{u}\cap R[t] \end{array}$$

Combining these we have a one-to-one correspondence of the spectrum of $E[t]$ and the prime ideals $\mathfrak{p}$ of $R[t]$ satisfying $\mathfrak{p}\cap R = 0$ given by $\mathfrak{u}\mapsto\Phi^{-1}(\mathfrak{u})\cap R[t]$. Let us decode this ideal

$$\Phi^{-1}(\mathfrak{u})\cap R[t] \;=\; \Big\{\, f\in R[t]\mid f/1\in\Phi^{-1}(\mathfrak{u})\,\Big\} \;=\; \{\,f\in R[t]\mid \iota(f)\in\mathfrak{u}\,\}$$

So this is the direction from left to right of the correspondence given in the claim. It remains to verify the converse direction from right to left. That is we start with a prime ideal $\mathfrak{p}\trianglelefteq_{\mathfrak{i}} R[t]$ such that $\mathfrak{p}\cap R = 0$ and have to prove that this $\mathfrak{p}$ corresponds to the ideal

$$\widetilde{\mathfrak{p}} \;:=\; \left\{ \sum_{k=0}^{\infty}\frac{f[k]}{u}t^k \;\middle|\; f\in\mathfrak{p},\, u\neq 0 \right\}$$

That is we have to show $\big\{\, f\in R[t]\mid \iota(f)\in\widetilde{\mathfrak{p}}\,\big\} = \mathfrak{p}$. If $f\in\mathfrak{p}$ then $\iota(f)\in\widetilde{\mathfrak{p}}$ is clear from the function rules of ι and Φ. And conversely if $f\in R[t]$ satisfies $\iota(f)\in\widetilde{\mathfrak{p}}$ then there are some $g\in\mathfrak{p}$ and $u\neq 0$ such that for any $k\in\mathbb{N}$ we get $f[k]/1 = g[k]/u$. That is $uf[k] = g[k]$ and hence $uf = g\in\mathfrak{p}$, as this is true for any $k\in\mathbb{N}$. As $\mathfrak{p}$ is a prime ideal this implies $u\mathbf{1}\in\mathfrak{p}$ or $f\in\mathfrak{p}$. But $u\mathbf{1}\in\mathfrak{p}$ would mean $u\in\mathfrak{p}\cap R = 0$ in contradiction to $u\neq 0$. Thus we conclude $f\in\mathfrak{p}$ and hence we have established the direction right to left of the correspondence, too.

□

Proof of (7.27):

(i) If $g = 0$ then $g(f) = 0\in R[t]$ such that $\deg(g(f)) = -\infty$. And regardless of f we also have $\deg(f)\cdot\deg(g) = -\infty$, which is equal. So let us now assume $g\neq 0$ and denote $d = \deg(f)$ and

$e := \deg(g)$. Let us first look at powers of f. By the polynomial rule, we have

$$f^k \;=\; \left(\sum_{i=0}^{d} f[i]\,t^i\right)^k \;=\; \sum_{|\alpha|=k} \binom{k}{\alpha} \prod_{i=0}^{d} f[i]^{\alpha_i} t^{i\cdot\alpha_i}$$

where the sum runs over all $\alpha = (\alpha_0, \ldots, \alpha_d) \in \mathbb{N}^{d+1}$ such that $|\alpha| = \alpha_0 + \cdots + \alpha_d = k$. Let us abbreviate $f[\alpha] := f[0]^{\alpha_0} \ldots f[d]^{\alpha_d}$ and $\omega(\alpha) := 0\cdot\alpha_0 + 1\cdot\alpha_1 + \ldots d\cdot\alpha_d$, then we use this formula to find an expression for $g(f) \in R[t]$

$$g(f) \;=\; \sum_{k=0}^{d} g[k]\, f^k \;=\; \sum_{k=0}^{d} g[k] \sum_{|\alpha|=k} \binom{k}{\alpha} f[\alpha]\, t^{\omega(\alpha)}$$

In particular, for $k = e$ and $\alpha = (0, \ldots, 0, e)$ the binomial coefficient k over α turns to 1 and $f[\alpha] = f[d]^e$ and $\omega(\alpha) = d\cdot e = \deg(f)\cdot\deg(g)$. The de-th coefficient of $g(f)$ thereby is

$$g(f)[de] \;=\; g[e]\cdot f[d]^e \;\neq\; 0$$

which is non-zero, as R is an integral domain. For any other combination (k, α) we have $\omega(\alpha) < de$, such that this truly is the leading coefficient of $g(f)$. In particular we have $\deg(g(f)) = d\cdot e$.

(ii) Let us first regard the case $n = 1$, that is $f \in R[t_1]$ and $g \in R[x]$. If $g(f) = 0$ then by (i) we have $\deg(f)\cdot\cdot(g) = \deg(g(f)) = -\infty$. But as $\deg(f) \geq 1$ this means $\deg(g) = -\infty$ and hence $g = 0$. Thus we have proved the claim, for $n = 1$.

Note that $n = 0$ is ruled out, as $\deg(f) \geq 1$ requires at least one variable. Now for general $2 \leq n \in \mathbb{N}$ there is some $i \in 1 \ldots n$ such that $\deg_i(f) \geq 1$, as we else would have $\deg(f) \leq 0$. For ease of notation we assume $i = 1$ and let $\mathfrak{a} := \langle t_2, \ldots, t_n \rangle_{\mathrm{i}}$. Then it is clear that

$$\Phi \;:\; R[t_1] \;\xrightarrow{\sim}\; R[t_1, \ldots, t_n] \Big/ \mathfrak{a} \;:\; f \mapsto f + \mathfrak{a}$$

is an isomorphism of R-algebras. As $g(f) = 0$ we also have $0 + \mathfrak{a} = g(f) + \mathfrak{a} = g(f + \mathfrak{a})$. Let us denote the preimage of $f + \mathfrak{a}$ in $R[t_1]$ by $\overline{f} := \Phi^{-1}(f + \mathfrak{a})$, that is $\overline{f} = \sum_{\alpha_1} f_\alpha(0) t_1^{\alpha_1}$ for some $f_\alpha \in R[t_2, \ldots, t_n]$. Then $\overline{f}$ is a polynomial in one variable t_1 and as $\deg_1(f) \geq 1$ we know $f \notin \mathfrak{a}$. That is $f + \mathfrak{a} \neq 0 + \mathfrak{a}$ and hence $\overline{f} \neq 0$, too. Since we also have

$$0 \;=\; \Phi^{-1}\big(g(f) + \mathfrak{a}\big) \;=\; g\big(\Phi^{-1}(f + \mathfrak{a})\big) \;=\; g(\overline{f})$$

we conclude from the case $n = 1$ that we must have had $g = 0$. That is we have proved the general claim $g(f) = 0 \implies g = 0$ and the converse implication $g = 0 \implies g(f)$ is trivial.

(iii) The element $p \in R$ is prime, if and only if the ideal $pR \trianglelefteq_{\mathrm{i}} R$ is prime. And by (2.12) this is equivalent to $S := R/pR$ being an integral domain. This again is equivalent to $S[t \mid A]$ being an integral domain, according to (7.12.(vii)). Now recall the isomorphy of (7.13)

$$A \Big/ pA \;\xrightarrow{\sim}\; S[t \mid A] \;:\; f + pA \mapsto \overline{\varrho}(f)$$

This means that $S[t \mid A]$ is an integral domain if and only if A/pA is. And as we have just argued

this is equivalent to $p \in A$ being prime.

(iv) Let us first consider the case of one variable $A = R[t]$ and some $a \in R$. Now suppose $(t-a) \mid fg$ for some $f, g \in R[t]$. That is there is some $u \in R[t]$ such that $fg(t) = u(t)(t-a)$. In particular, if we evaluate this expression in a, we find

$$f(a)g(a) \;=\; fg(a) \;=\; u(a)(a-a) \;=\; 0$$

As R is an integral domain this means $f(a) = 0$ or $g(a) = 0$. Without loss of generality we continue with the case $f(a) = 0$. Then we use (7.23.(v)) to write f as $f(t) = q(t)(t-a) + f(a) = q(t)(t-a)$. Thus we have already found $(t-a) \mid f$ in $R[t]$ and as this is true for any f, g we find $t - a \in R[t]$ to be a prime element of $R[t]$.

Generally for $t_i - a_i \in A$ we consider any $f, g \in A$, such that $(t_i - a_i) \mid fg$ again. Next we consider $fg \in S[t_i]$ as a polynomial in one variable over $S = R[t_j \mid j \in I \setminus \{i\}]$. Note that S is an integral domain again, according to (7.12.(vii)). Hence by the above $(t_i - a_i) \mid fg$ implies (without loss of generality) $(t_i - a_i) \mid f$ in $S[t_i] = A$, such that $t_i - a_i$ is prime in A.

(v) First of all t_iA is a prime ideal, as t_i is prime, according to (iii). A direct argument would be: Let $A_i := R[t_j \mid j \in I \setminus \{i\}]$, then we have an obvious isomorphism $A_i \xrightarrow{\sim} A/t_iA$ of R-algebras, by $f \mapsto f + t_iA$. But as R is an integral domain, so is A_i and hence t_iA has to be a prime ideal.

Let us now prove, that t_iA also is minimal over 0: If $\mathfrak{p} = 0$, then we are done, else choose some $g \in \mathfrak{p}$ with $g \neq 0$ and write this g as a polynomial in t_i over the ring A_i

$$g \;=\; \sum_{k=0}^{d} g_k\, t_i^k \;\in\; A_i[t_i]$$

As we have $g \in \mathfrak{p} \subseteq t_iA$ we see $g_0 = 0$. Also, for $d = \deg_i(g)$ we have $g_d \neq 0$. Now let $m \in \mathbb{N}$ be the minimal number, such that $g_m \neq 0$ As $g_0 = 0$ we have $m \in 1 \ldots d$. As $g_0 = \cdots = g_{m-1} = 0$ we can write g as $g = t_i^m f$ for $f = g_m + \cdots + g_d t_i^{d-m}$ and thereby

$$t_i^m f \;=\; g \;\in\; \mathfrak{p} \;\subseteq\; t_iA$$

As $\mathfrak{p}$ is prime and $m \geq 1$ we conclude $t_i \in \mathfrak{p}$ or $f \in \mathfrak{p}$. Suppose $f \in \mathfrak{p}$ was true, as $\mathfrak{p} \subseteq t_iA$ this would mean $0 + t_iA = f + t_iA = g_m + t_iA$ which is untrue, as $0 \neq g_m \in A_i$. So it must be $t_i \in \mathfrak{p}$, which is $t_iA \subseteq \mathfrak{p} \subseteq t_iA$ such that $\mathfrak{p} = t_iA$, as claimed.

□

Proof of (2.7):

(i) Let us regard the evaluation homomorphism $\varepsilon_a : F[t] \twoheadrightarrow F : f \mapsto f(a)$. As $f(a) = 0$ and $(t - a\mathbf{1}) \mid f$ are equivalent, according to (7.54.(iii)), we find

$$\mathrm{kn}(\varepsilon_a) \;=\; (t - a\mathbf{1})F[t]$$

But as ε_a is surjective the first isomorphism theorem (1.83.(ii)) tells us, that it induces an isomorphism of the form $F[t]/\mathrm{kn}(\varepsilon_a) \xrightarrow{\sim} F : f + \mathrm{kn}(\varepsilon_a) \mapsto f(a)$. As F is a field, so is $F[t]/\mathrm{kn}(\varepsilon_a)$ and this

again means, that $\mathrm{kn}(\varepsilon_a) = (t - a\mathbf{1})F[t]$ is a maximal ideal. Hence the map $a \mapsto (t - a\mathbf{1})F[t]$ is well-defined. It remains to show, that it also is injective: Suppose $(t - a\mathbf{1})F[t] = (t - b\mathbf{1})F[t]$ for some $a, b \in F$. Then we have $t - b\mathbf{1} \in (t - a\mathbf{1})F[t]$ which is $t - b\mathbf{1} = g(t) \cdot (t - a\mathbf{1})$. In particular $1 = \deg(g) + 1$ such that $\deg(g) = 0$. This again means $g = u\mathbf{1}$ for some $u \in F$. But then again $t - b\mathbf{1} = u\mathbf{1} \cdot (t - a\mathbf{1}) = ut - ua\mathbf{1}$. Comparing the coefficient in front of t we find $u = 1$ and hence $t - a\mathbf{1} = t - b\mathbf{1}$. Comparing the coefficients in front of $\mathbf{1}$ we also find $a = b$.

(ii) If $j \in \mathrm{JAC}(F[t])$ then by (2.8) using $a = 1$, we get $\mathbf{1} - j \in F[t]^*$. But by (7.23.(vii)) this means $\mathbf{1} - j = a\mathbf{1}$ for some $a \in F^*$. This again is $j = (1 - a)\mathbf{1}$. Now $tF[t]$ is a maximal ideal of $F[t]$, by (i) and as j is contained in *any* maximal ideal we in particular have $j \in tF[t]$. That is $j = g(t) \cdot t$ for some $g \in F[t]$ and thereby $j = 0$ or $0 = \deg(j) = \deg(g) + 1$. The latter is absurd, as $\deg(g)$ would have to be negative (which is $g = 0$) such that we get $j = 0$.

(iii) By the correspondence theorem of ideals (1.66), the ideals of $\mathbb{Z}_n$ are of the for $m\mathbb{Z}/n\mathbb{Z}$ for some $n\mathbb{Z} \subseteq m\mathbb{Z}$. The latter is $m \mid n$ and by the third isomorphism theorem (1.83.(iv)) we have

$$\mathbb{Z}/n\mathbb{Z} \Big/ m\mathbb{Z}/n\mathbb{Z} \xrightarrow{\sim} \mathbb{Z} \Big/ m\mathbb{Z} \;:\; (a + n\mathbb{Z}) + m\mathbb{Z} \Big/ n\mathbb{Z} \mapsto a + m\mathbb{Z}$$

Therefore $m\mathbb{Z}/n\mathbb{Z}$ is maximal if and only if $\mathbb{Z}_m$ is a field and this is the case iff m is prime. As $m \mid n$ this leaves $m \in \{ p_1, \ldots, p_r \}$, that is the maximal ideals of $\mathbb{Z}_n$ are the $p_i\mathbb{Z}/n\mathbb{Z}$ for $i \in 1 \ldots r$. Let $q := p_1 \ldots p_r$ then $q\mathbb{Z}/n\mathbb{Z}$ is contained in any $p_i\mathbb{Z}/n\mathbb{Z}$. Conversely if $a + n\mathbb{Z} \in \mathrm{JAC}(\mathbb{Z}_n)$ then $a + n\mathbb{Z} \in p_i\mathbb{Z}/n\mathbb{Z}$ means $a \in p_i\mathbb{Z}$ which is $p_i \mid a$. As the p_i are distinct primes, we conclude $q \mid a$ and hence $a + n\mathbb{Z} \in q\mathbb{Z}/n\mathbb{Z}$. Altogether we have the equality $\mathrm{JAC}(\mathbb{Z}_n) = q\mathbb{Z}/n\mathbb{Z}$.

Proof of (7.29):

(i) If $a \mid c \in \mathrm{cont}(f)$ then $a \mid c \mid f[\alpha]$ for any $\alpha \in \mathbb{N}^{\oplus I}$ say $f[\alpha] = a \cdot h[\alpha]$. Thereby $f = ah$ where $h \in A$ such that $a \mid f$ in A is granted. If conversely $a \mid h$ in A then $f = ah$ for some $h \in A$. But this is $f[\alpha] = a \cdot h[\alpha]$ such that $a \mid f[\alpha]$ for any $\alpha \in \mathbb{N}^{\oplus I}$. As c is a *greatest* common divisor of the $f[\alpha]$ this implies $a \mid c$.

(ii) If $c \in \mathrm{cont}(f)$ then by (i) we have $c \mid f$ such that $f = cf_1$ for some $f_1 \in A$. Take $b \in \mathrm{cont}(f_1)$, then $b \mid f_1$ such that $f_1 = bh$ for some $h \in A$. Hence $f = cbh$ which means $cb \mid f$. By (i) again this means $cb \mid c$ such that $b \mid 1$. That is $b \in R^{ast}$ such that f_1 is primitive.

Conversely if $f = cf_1$ for some primitive f_1 we take $d \in \mathrm{cont}(f)$. By (i) $c \mid f$ implies $c \mid d$. Let's say $d = ac$ Then by (i) again $ac = d \mid f = cf_1$ implies $a \mid f_1$ such that by (i) once again we get $a \mid 1$, as f_1 is primitive. That is $a \in R^*$ and hence $c \approx d \in \mathrm{cont}(f)$ which is $c \in \mathrm{cont}(f)$.

(iii) As $u \in B$ any coefficient $u[\alpha]$ is of the form $u[\alpha] = a[\alpha]/b[\alpha] \in E$, for some $a[\alpha]$ and $0 \neq b[\alpha] \in R$. As $u \neq 0$ there is some α with $u[\alpha] \neq 0$ and therefore we may take

$$b \;:=\; \mathrm{lcm}\Big(\Big\{ b[\alpha] \mid \alpha \in \mathbb{N}^{\oplus I}, u[\alpha] \neq 0 \Big\} \Big)$$

Note that we thereby take the least common multiple of a finite set and as R is an integral domain this implies $b \neq 0$ according to (2.57.(iii)). Then $(bu)[\alpha] = bu[\alpha] \in R$ for any $\alpha \in \mathbb{N}^{\oplus I}$ such that

$bu \in A$. Now let $a \in \mathrm{cont}(bu)$ and write $bu = au_1$ for some primitive $u_1 \in A$ using (ii). As $bu \neq 0$ it is clear, that $a \neq 0$, as well. Then we compute

$$bu \;=\; au \quad\Longrightarrow\quad u \;=\; \frac{a}{b}u_1$$

(iv) Let us first prove that the set $U \subseteq A$ of primitive polynomials is multiplicatively closed: As $\mathbf{1} \in A$ is a polynomial with $1 \in \mathrm{cont}(\mathbf{1})$ we have $1 \in U$. Now consider some $f, g \in U$ and let $c \in \mathrm{cont}(fg)$. If we had $c \notin R^*$ then [by prime decomposition of c] there would be some prime $p \in R$ such that $p \mid c$. By (i) this is $p \mid fg$ in A and by (7.27.(iii)) p is prime in A as well. W.l.o.g. we may take $p \mid g$ and if $d \in \mathrm{cont}(g)$ then this means $p \mid d$ according to (i). But g is primitive and hence $d \in R^*$ would imply $p \in R^*$ in contradiction to p being prime. This contradiction can only be avoided, if $c \in R^*$ and hence $1 \in \mathrm{cont}(fg)$. That is $fg \in U$ is primitive again.

By (ii) we may write $f = cf_1$ and $g = dg_1$ for some primitive f_1 and $g_1 \in A$. Then $fg = cd(f_1g_1)$ and as we have just seen f_1g_1 is primitive again. In particular we have $cd \in \mathrm{cont}(fg)$ according to (ii).

(v) Let us begin with the case in which $\star$ abbreviates *primitive*: Then we pick up primitive polynomials f and $g \in R[t]$ such that $u = \frac{a}{b}f$ and $v = \frac{c}{d}g$ according to (iii). In particular $bduv = acfg$. But as the content is multiplicative, we hence find

$$bd\,\mathrm{cont}(uv) \;=\; \mathrm{cont}(bduv) \;=\; \mathrm{cont}(acfg) \;=\; ac\,\mathrm{cont}(fg)$$

But by assumption uv is primitive and hence $1 \in \mathrm{cont}(uv)$. Also f and g are primitive and hence fg is primitive, due to (iv). That is $1 \in \mathrm{cont}(fg)$, as well and hence $bdR^* = acR^*$. That is we have $bd = \alpha ac$ for some $\alpha \in R^*$. Now let $u_1 := \alpha^{-1}f \in R[t]$ and $v_1 := g \in R[t]$, then we get $\frac{\alpha a}{b}u_1 = \frac{a}{b}f = u$, keep $\frac{c}{d}v_1 = \frac{c}{d}g = v$ and thereby also

$$uv \;=\; \frac{\alpha a}{b}u_1\frac{c}{d}v_1 \;=\; \frac{\alpha ac}{bd}u_1v_1 \;=\; \frac{\alpha ac}{\alpha ac}u_1v_1 \;=\; u_1v_1$$

That is we have found the properties (2) and (3) but property (1) also is clear, as from $u_1 = \alpha^{-1}f$ for some $\alpha \in R^*$ we get $1 \in \mathrm{cont}(f) = \mathrm{cont}(u_1)$. That is we have proved the statement for primitive polynomials.

Let us continue with the case in which $\star$ abbreviates the word *monic*: In particular the monic polynomial uv is primitive and hence we may use the case above, to find primitive polynomials $f, g \in R[t]$, such that $uv = fg$ and $u = \frac{a}{b}f$ and $v = \frac{c}{d}g$ again. But uv even is monic and R is an UFD (in particular an integral domain). Hence we may compare leading coefficients and find $1 = \mathrm{lc}(uv) = \mathrm{lc}(fg) = \mathrm{lc}(f)\mathrm{lc}(g)$, according to (7.18). That is $\alpha := \mathrm{lc}(f) \in R^*$ and also $\mathrm{lc}(g) = \alpha^{-1}$. Now define $u_1 := \alpha^{-1}f$ and $v_1 := \alpha g$, then clearly $u_1, v_1 \in R[t]$ are monic. We also get $u_1v_1 = \alpha^{-1}f\alpha g = fg = uv$ and $u = \frac{a}{b}f = \frac{\alpha a}{b}u_1$ and $v = \frac{c}{d}g = \frac{c}{d}\alpha^{-1}v_1 = \frac{c}{\alpha d}v_1$. That is we have properties (1), (2) and (3) in the monic case, as well.

(vi) The direction " $\Longrightarrow$ " is trivial: If $p \mid f$ in A then there is some $q \in A$ with $pq = f$. As $q \in A \subseteq B$ this is $p \mid f$ in B, as well. Conversely suppose $p \mid f$ in B, that is $pq = f$ for some $q \in B$. If $f = 0$ then $p \mid f = 0$ in A is granted by $q = 0$. Hence we only need to concern ourselves with $f \neq 0$.

In this case we also have $h \neq 0$ and using (iii) we may write $q = (c/b)q_1$ for some $c/b \neq 0$ and some primitive $q_1 \in A$. Now compute

$$bf \;=\; bpq \;=\; p(bq) \;=\; p(cq_1) \;=\; cpq_1$$

Let $b = \beta p_1 \dots p_k$ be a prime decomposition of b then for any $i \in 1 \dots k$ we have $p_i \mid b \mid bf = cpq_1$. And as $p_i \in R$ is prime, so is $p_i \in A$ due to (7.27.(iii)). This yields $p_i \mid c$ or $p_i \mid p$ or $p_i \mid q_1$. But both p and $q_1 \in A$ are primitive, so this only leaves $p_i \mid c$ by (i). And as this is true for any $i \in 1 \dots k$ we find $b \mid c$, say $ab = c$. Then we continue

$$bf \;=\; cpq_1 \;=\; abpq_1 \quad\Longrightarrow\quad f \;=\; apq_1$$

and thereby find, that truly $p \mid f$ in A. Let us summarize: We started with $f = pq$ for some $q \in B$, where $q = (c/b)q_1$. It turned out that $c/b = a \in R$ such that $f = pq$ with $q \in A$ already.

(vii) Let us first prove the claim in case $\star =$ *irreducible*: Suppose p is irreducible, as an element of A and consider $p = uv$ for some $u, v \in B$. By (iii) above there is some $0 \neq b/c \in E$ and some primitive $v_1 \in A$ such that $v = (c/b)v_1$ equivalently $bv = c = v_1$. Then

$$p \;=\; uv \;=\; \big(b^{-1}u\big)\big(bv\big) \;=\; \big(b^{-1}u\big)\big(cv_1\big) \;=\; \big(cb^{-1}u\big)v_1$$

Hence $v_1 \mid p$ in B and by (vi) that is $v_1 \mid p$ in A. That is we have $v_1 h = p$ for some $h \in A$. As p was assumed to be irreducible in A this implies v_1 or $h \in A^* = R^*$. Recall that $v = cb^{-1}v_1$ and $v_1 h = p = uv = ucb^{-1}v_1$. Then $h = cb^{-1}u$ and hence $u = bc^{-1}h$. If $v_1 \in R^*$ then $v = cb^{-1}v_1 \in E^* = B^*$ and if $h \in R^*$ then $u = bc^{-1}h \in E^* = B^*$. Therefore p is irreducible in B. [Note that we did not require the primivitity of p for this direction].

Conversely suppose p is irreducible, as an element of B and consider $p = fg$ for some $f, g \in A$. In particular f or $g \in B^* = E^*$. W.l.o.g. let us assume $f \in E^*$. That is $f = f[0] \neq 0$. If now $c \in \mathrm{cont}(f)$ and $d \in \mathrm{cont}(g)$, then by (iv) we have $cd \in \mathrm{cont}(fg) = \mathrm{cont}(p)$. But p was assumed to be primitive and hence $\mathrm{cont}(p) = R^*$ such that $c \in R^*$. But as $f = f[0]$ we have $f[0] \in \mathrm{cont}(f) = cR^* = R^*$ and therefore $f \in R^* = A^*$. And this is the irreducibility of p in A.

Now we prove the claim in case $\star =$ *prime*: Suppose p is prime, as an element of B. As we want to prove that p is prime in A we consider some $f, g \in A$ such that $p \mid fg$ in A. In particular $p \mid fg$ in B and hence $p \mid f$ or $p \mid g$ in B. But by (vi) this is $p \mid f$ or $p \mid g$ in A and this is the prime property of p in A.

Conversely suppose p is prime as an element of A and remember $p \notin R$. We need to show that p is prime in B, that is we consider $u, v \in B$ such that $p \mid uv$ in B. By (iii) there are some $a, b \in R$ such that au and $bv \in A$. And $p \mid uv$ implies $p \mid (au)(bv)$ in B, as well. But as p is primitive (i) implies $p \mid (au)(bv)$ in A from which we get $p \mid au$ or $p \mid bv$ in A, as p was assumed to be prime in A. Once again this implies $p \mid a$ or $p \mid u$ or $p \mid b$ or $p \mid v$ in A. But as $a, b \in R$ and $p \notin R$ the possibilities $p \mid a$ and $p \mid b$ are absurd, so we are left with $p \mid u$ or $p \mid v$ in A. Trivially this implies $p \mid u$ or $p \mid v$ in B, such that p is prime in B.

(viii) Let us fist prove the implication A is an UFD $\Longrightarrow$ R is an UFD. As R is a sub-ring of A and A

is an UFD, R is an integral domain. Now consider any $0 \neq a \in R$, by assumption a has a prime decomposition $a = \alpha p_1 \dots p_k$ in A, that is $\alpha \in A^* = R^*$ and $p_i \in A$ are prime. As $a \in R$ we have $p_i \in R$ by (7.22). As p_i is prime in A so it is in R, by (7.27.(iii)). Thus we already have a prime decomposition $a = \alpha p_1 \dots p_k$ of a. And as $a \neq 0$ was arbitrary this means that R is an UFD.

The proof of the converse implication R is an UFD $\implies$ A is an UFD will be conducted in three steps: In a first step let us assume $\#I = 1$, that is $A = R[t]$ is the polynomial ring in one variable. By assumption R is an UFD, then we need to show that $A = R[t]$ is an UFD, as well. We already know that A is an integral domain, by (7.12.(vii)). Now consider any $0 \neq f \in A$, if $\deg(f) = 0$ then $f \in R$ and as R was assumed to be an UFD we find a prime decomposition $f = \alpha p_1 \dots p_k$ in R. As any $p_i \in R$ is prime in R, it also is prime in A, once more. Also $\alpha \in R^* = A^*$ such that $f = \alpha p_1 \dots p_k$ also is a prime decomposition of f in A. If $\deg(f) \geq 1$, then we note that $B = E[t]$ is a PID and in particular an UFD by (2.71.(iii)) and (2.79.(ii)) respectively. Therefore f has a prime decomposition $f = \alpha v_1 \dots v_k$ in B. That is $\alpha \in B^* = E^*$ and $v_i \in B$ are prime. In particular we have $v_i \notin E$. By above there are some $0 \neq c_i/b_i \in E$ and primitive $p_i \in A$ such that $v_i = (c_i/b_i)p_i$. Note that $p_i \notin R$, as $v_i \notin E$. Now define $b := b_1 \dots b_k$ and $c := c_1 \dots c_k$ and $p := p_1 \dots p_k$ then we compute

$$bf \;=\; \alpha b \prod_{i=1}^{k} v_i \;=\; \alpha \prod_{i=1}^{k} (b_i v_i) \;=\; \alpha \prod_{i=1}^{k} (c_i p_i) \;=\; \alpha c p$$

As the $p_i \in A$ are primitive, so is p, due to (iv). And as $f = \alpha(c/b)p$ we have $p \mid f$ in B. But by (vi) this implies $p \mid f$ in A such that $ph = f$ for some $h \in A$. That is $ph = f = \alpha(c/b)p$ such that $h = \alpha(c/b) \in A \cap E^* = R \setminus \{0\}$. As R is an UFD h admits a prime decomposition in R. And by (7.27.(iii)) this also is a prime decomposition in A. Also $c_i p_i = b_i v_i$ implies $p_i = (b_i/c_i)v_i \approx v_i$ in B. As v_i is prime in B this implies that p_i is prime in B, as well. And by (vi) p_i is prime in A such that $p = p_1 \dots p_k$ is a prime decomposition of p. As both h and p have a prime decomposition, so does $f = ph$. And as f was arbitrary this shows, that A is an UFD.

If $\#I < \infty$, say $I = \{1, \dots, n\}$ then we can prove the equivalence of R and A being UFDs by induction on n: The case $n = 1$ has just been established and for the induction step we use the isomorphy (7.23.(iii))

$$R[t_1, \dots, t_n, t_{n+1}] \quad \cong_{\mathsf{a}} \; A[t_{n+1}]$$

where $A := R[t_1, \dots, t_n]$. By induction hypothesis R is an UFD if and only if A is such. And by the case $n = 1$ we know that A is an UFD if and only if $A[t_{n+1}]$ is such. Thus R is an UFD if and only if $A[t_{n+1}]$ and hence $R[t_1, \dots, t_n, t_{n+1}]$ is such. Thus the induction is complete.

For general I we note that any $f \in A$ is contained in a polynomial ring with finitely many variables only. To be precise let

$$\Omega \;:=\; \Big\{ i \in I \mid \exists\, \alpha \in \mathbb{N}^{\oplus I} \,:\, f[\alpha] \neq 0 \text{ and } \alpha_i \neq 0 \Big\}$$

then we have $f \in R[t_i \mid i \in \Omega]$ and $\Omega \subseteq I$ is finite since there are finitely many α with $f[\alpha] \neq 0$ only and all of these have $\alpha_i \neq 0$ for finitely many $i \in I$ only. Thus as R is an UFD and Ω is finite $S := R[t_i \mid i \in \Omega]$ is an UFD, as well. Thus any $0 \neq f \in S$ has a prime decomposition $f = \alpha p_1 \dots p_k$ in S. That is $\alpha \in S^* = R^*$ and the $p_i \in S$ are prime. As $A = R[t_i \mid i \in I] \;\cong_{\mathsf{a}}\; S[t_i \mid i \in I \setminus \Omega]$

we find by (7.27.(iii)) that the p_i are prime in A, as well. Thus $f = \alpha p_1 \dots p_k$ also is a prime decomposition of f in A. And as f was arbitrary this means that A is an UFD.

□

Proof of (7.30):

(i) We have to verify that for any two Laurent series $f, g \in L$ and any $\gamma \in \mathbb{Z}^n$ the set $I := \{ (\alpha, \beta) \mid \alpha + \beta = \gamma, f[\alpha] \neq 0, g[\beta] \neq 0 \}$ of indexes is finite. To show this let us denote $[\alpha] := \min\{ \alpha_i \mid i \in 1 \dots n \}$. As $f \in L$ by definition there is some $k \in \mathbb{Z}$ such that $f[\alpha] \neq 0$ implies $[\alpha] \geq k$ and likewise $g[\beta] \neq 0$ implies $[\beta] \geq \ell$ for some $\ell \in \mathbb{Z}$. Then it is clear, that $I \subseteq \{ (\alpha, \beta) \mid \alpha + \beta = \gamma, k \leq [\alpha], \ell \leq [\beta] \}$. And clearly we have $[\alpha + \beta] \geq [\alpha] + [\beta]$ such that $[\gamma] = [\alpha + \beta] \geq [\alpha] + [\beta] \geq [\alpha] + \ell$ from which we get $[\alpha] \leq [\gamma] - \ell$. Inserting $\beta = \gamma - \alpha$ and this inequality into I we finally get the upper bound $I \subseteq \{ (\alpha, \gamma - \alpha) \mid k \leq [\alpha] \leq [\gamma] - \ell \}$ and this finally is a finite set.

(ii) If $f \in L$ then by definition there is some $\ell \in \mathbb{Z}$ such that $f[\alpha] \neq 0$ implies $\alpha_i \geq \ell$ and hence (since $\omega_i \geq 0$ as well) we get $\omega_i \alpha_i \geq \omega_i \ell$. Altogether

$$|\alpha|_\omega \;=\; \sum_{i=1}^{n} \omega_i \alpha_i \;\geq\; \sum_{i=1}^{n} \omega_i \ell \;=\; |\omega| \cdot \ell$$

Hence the set $\{ |\alpha|_\omega \mid \alpha \in \mathbb{Z}^n,\ f[\alpha] \neq 0 \}$ is bounded from below, by $|\omega| \cdot \ell$ and therefore has a minimal element.

(iii) Let us define a partial order on $\mathbb{Z}^n$ by taking $\alpha \leq \beta$ if and only if $|\alpha|_\omega \geq |\beta|_\omega$. Then $\leq$ even is a positive order on $\mathbb{Z}^n$, as for any α, α' and $\beta \in \mathbb{Z}^n$ we get: $\alpha \leq \alpha'$ is $|\alpha|_\omega \geq |\alpha'|_\omega$ such that $|\alpha + \beta|_\omega = |\alpha|_\omega + |\beta|_\omega \geq |\alpha'|_\omega + |\beta|_\omega = |\alpha' + \beta|_\omega$ which again is $\alpha + \beta \leq \alpha' + \beta$. And also we find the equality

$$\begin{aligned} \operatorname{ord}_\omega(f) &= \min\{ |\alpha|_\omega \mid f[\alpha] \neq 0 \} \\ &= |\max\nolimits_{\leq} \{ \alpha \mid f[\alpha] \neq 0 \}|_\omega \;=\; |\deg(f)|_\omega \end{aligned}$$

And as $\mathbb{Z}^n$ is an integral monoid (it even is a group) we find the following inequality (with respect the positive order $\leq$ on $\mathbb{Z}^n$) according to (7.18)

$$\deg(f\,g) \;\leq\; \deg(f) + \deg(g)$$

And by definition of $\leq$ this is $|\deg(f\,g)|_\omega \geq |\deg(f) + \deg(g)|_\omega = |\deg(f)|_\omega + |\deg(f)|_\omega$ again. And from this the above equality implies $\operatorname{ord}_\omega(f\,g) \geq \operatorname{ord}_\omega(f) + \operatorname{ord}_\omega(g)$. If R is an integral domain (as $\mathbb{Z}^n$ being a group and hence integral, too) then (7.18) even yields an equality here. And for arbitrary R we already get

$$\deg(f+g) \;\leq\; \max\{ \deg(f), \deg(g) \}$$

with respect to the positive order $\leq$. But according to its definition this is $|\deg(f+g)|_\omega \geq \min\{ |\deg(f)|_\omega, |\deg(g)|_\omega \}$ again, such that we also get $\operatorname{ord}_\omega(f+g) \geq \min\{ \operatorname{ord}_\omega(f), \operatorname{ord}_\omega(g) \}$.

(iv) Clearly U is multiplicatively closed, as $(\mathbb{N}^n,+) \to (P,\cdot) : \alpha \mapsto t^\alpha$ is a monoid homomorphism, whose image is U precisely. As t^α has the inverse element $t^{-\alpha} \in L$ we also have $U \subseteq L^*$. Thus, regarding the embedding $\iota : P \to L : f \mapsto f$, we see that $\iota(U) \in L^*$. Hence the universal property of localization of rings (2.120) yields a well-defined homomorphism of rings $\Phi := \bar{\iota} : U^{-1}P \to L$ by taking $\Phi(f/t^\alpha) = f \cdot t^{-\alpha}$. It remains to show, that this homomorphism in fact is an isomorphism. For the injectivety let us take some f, $g \in P$ and α, $\beta \in \mathbb{N}^n$ such that $t^{-\alpha}f = t^{-\beta}g$. But multiplying this equality with $t^{0+\alpha+\beta}$ we get $t^0 t^\beta f = t^0 t^\alpha g$ such that truly $f/t^\alpha = g/t^\beta$. For the surjectivety we are given some $g \in L$ and need to find $f \in P$ and $\alpha \in \mathbb{N}^n$ such that $g = t^{-\alpha}f$. To do this we define $\alpha_i \in \mathbb{N}$ as follows: if $\mathrm{ord}_i(g) \geq 0$ take $\alpha_i := 0$ otherwise - if $\mathrm{ord}_i(g) < 0$ - take $\alpha_i := -\mathrm{ord}_i(g) > 0$. Then it is clear that $\alpha_i \geq 0$ and hence $\alpha \in \mathbb{N}^n$. Letting $f := t^\alpha g$ we get $\mathrm{ord}_i(f) \geq \mathrm{ord}_i(t^\alpha) + \mathrm{ord}_i(g) = \alpha_i + \mathrm{ord}_i(g)$. If $\mathrm{ord}_i(g) \geq 0$ then $\alpha_i = 0$ and hence $\mathrm{ord}_i(f) = \mathrm{ord}_i(g) \geq 0$. If conversely $\mathrm{ord}_i(g) < 0$, then $\alpha_i = -\mathrm{ord}_i(g)$ and hence $\mathrm{ord}_i(f) = 0$. In any case we have $\mathrm{ord}_i(f) \geq 0$ and hence $f \in P$. And by construction it is clear, that $g = t^{-\alpha}f$ establishing the surjectivety of Φ.

(v) If $f \in R[\![t]\!]$ is invertible, then there is some $g \in R[\![t]\!]$ such that $fg = 1$. In particular we get $1 = 1[0] = fg[0] = f[0] \cdot g[0]$ and hence $f[0] \in R$ is invertible, too. Conversely suppose are given som $f \in R[\![t]\!]$ such that $f[0] \in R^*$. Then we need to find some $g \in R[\![t]\!]$ such that $fg = 1$. To do this first recall the definition of fg:

$$\begin{aligned} fg &= \left(\sum_{i=0}^{\infty} f[i]t^i\right)\left(\sum_{j=0}^{\infty} g[j]t^j\right) \\ &= \sum_{k=0}^{\infty}\left(\sum_{i+j=k} f[i]\cdot g[j]\right)t^k \\ &= \sum_{k=0}^{\infty}\left(\sum_{j=0}^{k} f[k-j]\cdot g[j]\right)t^k \end{aligned}$$

Let us now construct g with $fg = 1$ by recursively defining its coefficients, starting with $g[0] := f[0]^{-1} \in R$. Suppose we already have $g[0],\ldots,g[k-1]$, then we take $g[k]$ to be

$$g[k] := -f[0]^{-1}\left(\sum_{j=1}^{k-1} f[k-j]g[j]\right)$$

We will now prove $fg = 1$: First of all $fg[0] = f[0]\cdot g[0] = f[0]\cdot f[0]^{-1} = 1$ is clear and for $k \geq 1$ we also find $fg[k] = 0$ by construction

$$fg[k] = \sum_{j=0}^{k} f[k-j]\cdot g[j] = \sum_{j=0}^{k-1} f[k-j]\cdot g[j] + f[0]\cdot g[k] = 0$$

(vi) Clearly $t^{-\mathrm{ord}(g)}f \in L$ and according to (v) we also find that $t^{-\mathrm{ord}(g)}g \in P^* \subseteq L^*$ is invertible. Hence the expression

$$\Phi(f/g) := t^{-\mathrm{ord}(g)}f \cdot (t^{-\mathrm{ord}(g)}g)^{-1}$$

is well-defined. Next we will prove that the homomorphism Φ is well-defined, as well. To do this

consider f, g, h and $k \in P$ with $g, k \neq 0$ such that $f/g = h/k$. Let us also abbreviate $u := t^{-\mathrm{ord}(g)}g$ and $v := t^{-\mathrm{ord}(k)}k$, then $f/g = h/k$ means $fk = gh$ since P is an integral domain. And multiplying this equation with $t^{-\mathrm{ord}(gk)}$ we get

$$t^{-\mathrm{ord}(g)}fv \;=\; t^{-\mathrm{ord}(g)}ft^{-\mathrm{ord}(k)}k \;=\; t^{-\mathrm{ord}(g)}gt^{-\mathrm{ord}(k)}h \;=\; t^{-\mathrm{ord}(k)}hu$$

But multiplying this equation with $u^{-1}v^{-1}$ again, we find $\Phi(f/g) = t^{-\mathrm{ord}(g)}fu^{-1} = t^{-\mathrm{ord}(k)}hv^{-1} = \Phi(h/k)$ which had to be shown. As all these equations have been equivalent this already establishes the injectivety of Φ. So let us now turn our attention to the homomorphism properties of Φ:

$$\begin{aligned}
\Phi\left(\frac{f}{g}\cdot\frac{h}{k}\right) &= \Phi\left(\frac{fh}{gk}\right) \;=\; t^{-\mathrm{ord}(gk)}fh\left(t^{-\mathrm{ord}(gk)}gk\right)^{-1} \\
&= t^{-\mathrm{ord}(g)}t^{-\mathrm{ord}(k)}fh\left(t^{-\mathrm{ord}(g)}t^{-\mathrm{ord}(k)}gk\right)^{-1} \\
&= t^{-\mathrm{ord}(g)}ft^{-\mathrm{ord}(k)}h\left(t^{-\mathrm{ord}(g)}g\right)^{-1}\left(t^{-\mathrm{ord}(k)}k\right)^{-1} \\
&= \Phi\left(\frac{f}{g}\right)\Phi\left(\frac{h}{k}\right) \\
\Phi\left(\frac{f}{g}+\frac{h}{k}\right) &= \Phi\left(\frac{fk+gh}{gk}\right) \;=\; t^{-\mathrm{ord}(gk)}(fk+gh)\left(t^{-\mathrm{ord}(gk)}gk\right)^{-1} \\
&= \left(t^{-\mathrm{ord}(g)}fv + t^{-\mathrm{ord}(k)}hu\right)(uv)^{-1} \\
&= t^{-\mathrm{ord}(g)}fu^{-1} + t^{-\mathrm{ord}(k)}hv^{-1} \;=\; \Phi\left(\frac{f}{g}\right)+\Phi\left(\frac{h}{k}\right)
\end{aligned}$$

It remains to prove the surjectivety if Φ: To do this consider any $\ell \in L$. If $\mathrm{ord}(\ell) \geq 0$, then $\ell \in P$ already and we take $r := 0$. Conversely, if $\mathrm{ord}(\ell) < 0$ then we take $r := -\mathrm{ord}(\ell) > 0$. Thus we always have $r \geq 0$ and hence $t^r \in P$. We also get $\mathrm{ord}(t^r\ell) = r + \mathrm{ord}(\ell) \geq 0$ such that $t^r\ell \in P$. Therefore we can compute

$$\Phi\left(\frac{t^r\ell}{t^r}\right) = t^{-\mathrm{ord}(t^r)}t^r\ell\left(t^{-\mathrm{ord}(t^r)}t^r\right)^{-1} = t^{-r}t^r\ell(t^{-r}t^r)^{-1} = \ell 1^{-1} = \ell$$

□

Proof of (7.70):

(i) By the product rule of derivations we find $d(1_A) = d_1(1_A \cdot 1_A) = d(1_A)\cdot 1_A + 1_A \cdot d(1_A) = d(1_A) + d(1_A)$. By subtracting $d(1_A)$ once, we obtain $0_A = d(1_A)$ from this. And as d also is R-linear $d(a1_A) = ad(1_A) = a0_A = 0_A$ for any $a \in R$, as well.

(ii) Let us prove the general product rule by induction on n. For $n = 1$ the identity is obvious, we only have $d(f_1)$ on both sides. For the induction step $n \mapsto n+1$ let us abbreviate $f := f_1 \cdot \ldots \cdot f_n$, then we use the product rule and induction hypothesis on the following term

$$d\big(f_1 \cdot \ldots \cdot f_{n+1}\big) \;=\; d\big(f \cdot f_{n+1}\big) \;=\; d(f)\cdot f_{n+1} + f \cdot d\big(f_{n+1}\big)$$

$$
\begin{aligned}
&= \left(\sum_{i=1}^{n} f_1 \cdot \ldots \cdot f_{i-1} \cdot d(f_i) \cdot f_{i+1} \cdot \ldots \cdot f_n\right) \cdot f_{n+1} + (f_1 \cdot \ldots \cdot f_n) \cdot d\big(f_{n+1}\big) \\
&= \sum_{i=1}^{n+1} f_1 \cdot \ldots \cdot f_{i-1} \cdot d(f_i) \cdot f_{i+1} \cdot \ldots \cdot f_{n+1}
\end{aligned}
$$

(iii) The first identity is clear by (ii): As A is commutative any of the n summands is of the form $d(f) \cdot f^{n-1}$ and as we have n summands this turns into $nd(f) \cdot f^{n-1}$. The second identity is clear for $m = 0$: $d^m(f \cdot g) = \mathbb{1}(f \cdot g) = f \cdot g$, same as $d^0(f) \cdot d^0(g) = f \cdot g$. For $m \geq 1$ we use induction on m. But this is a straightforward computation, basically, that uses the binomial recursion formula

$$
\begin{aligned}
d^{m+1}(f \cdot g) &= d\Big(d^m(f \cdot g)\Big) = d\left(\sum_{k=0}^{m} \binom{m}{k} d^k(f) \cdot d^{m-k}(g)\right) \\
&= \sum_{k=0}^{m} \binom{m}{k} d\big(d^k(f) \cdot d^{m-k}(g)\big) \\
&= \sum_{k=0}^{m} \binom{m}{k} \big(d^{k+1}(f) \cdot d^{m-k}(g) + d^k(f) \cdot d^{m-k+1}(g)\big) \\
&= \sum_{k=1}^{m} \binom{m}{k-1} d^k(f) \cdot d^{m-(k-1)}(g) + \sum_{k=0}^{m} \binom{m}{k} d^k(f) \cdot d^{m-k+1}(g) \\
&= d^{m+1}(f) \cdot g + \sum_{k=1}^{m} \left(\binom{m}{k-1} + \binom{m}{k}\right) d^k(f) \cdot d^{m+1-k}(g) + f \cdot d^{m+1}(g) \\
&= d^{m+1}(f) \cdot g + \sum_{k=1}^{m} \binom{m+1}{k} d^k(f) \cdot d^{m+1-k}(g) + f \cdot d^{m+1}(g) \\
&= \sum_{k=0}^{m+1} \binom{m+1}{k} d^k(f) \cdot d^{m+1-k)}(g)
\end{aligned}
$$

(iv) Let us first check the well-definedness of $U^{-1}d$: That is we start with any $f/u = g/v \in U^{-1}A$. That is $wvf = wug$ for some $w \in U$. This is $w(vf - ug) = 0$ and as U does not contain any zero-divisors, we get $vf - ug = 0$ which is $vf = ug$. Using this we have to show

$$
\frac{d(f) \cdot u - f \cdot d(u)}{u^2} = \frac{d(g) \cdot v - g \cdot d(v)}{v^2}
$$

Again we can omit the $w \in U$, as U does not contain zero-divisors such that this equation means $v^2(d(f) \cdot u - f \cdot d(u)) = u^2(d(g) \cdot v - g \cdot d(v))$. Rearranging terms, this equation is equivalent, to

$$
uv^2 d(f) + u^2 g d(v) = u^2 v d(g) + v^2 f d(u)
$$

In this equation we replace $u^2 g = u(ug)$ by $u(vf) = uvf$ and likewise we replace $v^2 f = v(vf)$ by $v(ug) = uvg$. Doing this we can factor out uv on both sides, to end up with the following equation

$$
uv\big(vd(f) + fd(v)\big) = uv\big(ud(g) + gd(u)\big)
$$

Yet $vf = ug$ also implies that $d(vf) = vd(f) + fd(v)$ equals $d(ug) = ud(g) + gd(u)$ such that the last equality holds true. Altogether we get the identity needed and thereby the well-definedness

of $U^{-1}d$. And as $d(1_A) = 0_A$ it is straightforward to see, that

$$U^{-1}d\left(\frac{f}{1}\right) \;=\; \frac{d(f)\cdot 1 - f\cdot d(1)}{1} \;=\; \frac{d(f)}{1}$$

So it remains to verify, that $U^{-1}d$ truly is a derivation on $U^{-1}A$. We commence by proving, the R-linearity, followed by the product rule. Consider any $a \in R$, f and $g \in A$ and u, $v \in U$, then we compute

$$\begin{aligned}
U^{-1}d\left(a\frac{f}{u}\right) &= U^{-1}d\left(\frac{af}{u}\right) = \frac{d(af)\cdot u - (af)\cdot d(u)}{u^2} \\
&= \frac{a\big(d(f)\cdot u - f\cdot d(u)\big)}{u^2} = a\frac{d(f)\cdot u - f\cdot d(u)}{u^2} \\
U^{-1}d\left(\frac{f}{u}+\frac{g}{v}\right) &= U^{-1}d\left(\frac{fv+gu}{uv}\right) \\
&= \frac{d(fv+gu)\cdot uv - (fv+gu)\cdot d(uv)}{u^2v^2}
\end{aligned}$$

The last term needs to be decomposed in parts: $d(fv+gu) = d(fv)+d(gu)$ as d is additive and using the product rule, this turns into $d(f)v + fd(v) + d(g)u + gd(u)$. Multiplying this by uv yields $uv^2d(f) + fuvd(v) + u^2vd(g) + guvd(u)$. Now for the second part: $d(uv) = d(u)v + ud(v)$. Multiplying this by fv yields $fv^2d(u) + fuvd(v)$. Likewise multiplication of $d(uv)$ by gu yields $guvd(u) + gu^2d(v)$. We see, that both $fuvd(v)$ and $guvd(u)$ occurs in the first and second parts and hence cancels each other, it only remains

$$\begin{aligned}
U^{-1}d\left(\frac{f}{u}+\frac{g}{v}\right) &= \frac{uv^2d(f) + u^2vd(g) - fv^2d(u) - gu^2d(v)}{u^2v^2} \\
&= \frac{uv^2d(f) - fv^2d(u)}{u^2v^2} + \frac{u^2vd(g) - gu^2d(v}{u^2v^2} \\
&= \frac{ud(f) - fd(u)}{u^2} + \frac{vd(g) - gd(v)}{v^2} \\
&= U^{-1}d\left(\frac{f}{u}\right) + U^{-1}d\left(\frac{g}{v}\right) \\
U^{-1}d\left(\frac{f}{u}\cdot\frac{g}{v}\right) &= U^{-1}d\left(\frac{fg}{uv}\right) = \frac{d(fg)\cdot uv - (fg)\cdot d(uv)}{u^2v^2} \\
&= \frac{guvd(f) + fuvd(g) - fgvd(u) - fgud(v)}{u^2v^2} \\
&= \frac{guvd(f) - fgvd(u)}{u^2v^2} + \frac{fuvd(g) - fgud(v)}{u^2v^2} \\
&= \frac{ud(f) - fd(u)}{u^2}\cdot\frac{gv}{v^2} + \frac{fu}{u^2}\cdot\frac{vd(g) - gd(v)}{v^2} \\
&= U^{-1}d\left(\frac{f}{u}\right)\cdot\frac{g}{v} + \frac{f}{u}\cdot U^{-1}d\left(\frac{g}{v}\right)
\end{aligned}$$

(v) The map $d \mapsto U^{-1}d$ is well-defined, according to (iv). It also is infective: Consider any two derivations d_1 and $d_2 \in \mathrm{der}(A)$ such that $U^{-1}d_1 = U^{-1}d_2$, then for any $f \in A$ we get

$$\frac{d_1(f)}{1} \;=\; U^{-1}d_1\left(\frac{f}{1}\right) \;=\; U^{-1}d_2\left(\frac{f}{1}\right) \;=\; \frac{d_2(f)}{1}$$

That is there is some $w \in U$ such that $wd_1(f) = wd_2(f)$, but as U does not contain any zero-divisors this is $d_1(f) = d_2(f)$ for any $f \in A$ and hence $d_1 = d_2$. The R-linearity of $d \mapsto U^{-1}d$ can be proved in a straightforward computation

$$\begin{aligned}
U^{-1}(ad)\left(\frac{f}{u}\right) &= \frac{(ad)(f)\cdot u - f\cdot(ad)(u)}{u^2} = \frac{ad(f)\cdot u - f\cdot ad(u)}{u^2} \\
&= a\frac{d(f)\cdot u - f\cdot d(u)}{u^2} = aU^{-1}d\left(\frac{f}{u}\right) \\
U^{-1}(d_1+d_2)\left(\frac{f}{u}\right) &= \frac{(d_1+d_2)(f)\cdot u - f\cdot(d_1+d_2)(u)}{u^2} \\
&= \frac{d_1(f)\cdot u + d_2(f)\cdot u - f\cdot d_1(u) - f\cdot d_2(u)}{u^2} \\
&= \frac{d_1(f)\cdot u - f\cdot d_1(u)}{u^2} + \frac{d_2(f)\cdot u - f\cdot d_2(u)}{u^2} \\
&= U^{-1}d_1\left(\frac{f}{u}\right) + U^{-1}d_2\left(\frac{f}{u}\right)
\end{aligned}$$

If $d \in \mathrm{der}(A)$, then $U^{-1}d(f/1) = d(f)/1$, as we have seen in (iv). Conversely, if $D \in \mathrm{der}(U^{-1}A)$ safisfies $D(f/1) = f'/1$ for some $f' \in A$, then $d : f \mapsto f'$ is a derivation on A. The R-linearity is clear and the product-rule follows from

$$\frac{(fg)'}{1} = D\left(\frac{fg}{1}\right) = D\left(\frac{f}{1}\right)\cdot\frac{g}{1} + \frac{f}{1}\cdot D\left(\frac{g}{1}\right) = \frac{f'\cdot g + f\cdot g'}{1}$$

By construction we have $D(f/1) = d(f)/1$, it remains to verify $D = U^{-1}d$: As D is a derivation we have $D(1/1) = 0$, but $u/u = 1/1$ such that $0 = D(u/u) = D(u/1)\cdot 1/u + u/1\cdot D(1/u)$ and this turns into $D(1/u) = -D(u/1)\cdot 1/u^2 = -d(u)/u^2$. Using this, we compute

$$\begin{aligned}
D\left(\frac{f}{u}\right) &= D\left(\frac{f}{1}\cdot\frac{1}{u}\right) = \frac{d(f)}{1}\cdot\frac{1}{u} + \frac{f}{1}\cdot D\left(\frac{1}{u}\right) \\
&= \frac{d(f)\cdot u}{u^2} - \frac{f}{1}\cdot\frac{d(u)}{u^2} = \frac{d(f)\cdot u - f\cdot d(u)}{u^2} = U^{-1}d\left(\frac{f}{u}\right)
\end{aligned}$$

□

Proof of (7.71):
First note, that by definition we have $(t^k)' = kx^{k-1}$ for $k \geq 1$ and $(t^k)' = 0$ for $k = 0$. By abuse of notation we can write this, as $(t^k)' = kt^{-1}$ even for $k = 0$, as $k = 0$ eliminates the term, even though t^{-1} is not a well defined element of $R[t]$. Then f' is defined by linear expansion of $d : t^k \mapsto kt^{k-1}$ from the R-basis $\left\{ t^k \mid k \in \mathbb{N} \right\}$ of $R[t]$. In particular $d : f \mapsto f'$ is R-linear. It remains to verify the product rule for any polynomials $f, g \in R[t]$:

$$(f\cdot g)' = \left(\sum_{k=0}^{\infty}\left(\sum_{i+j=k} f[i]g[j]\right)t^k\right)' = \sum_{k=1}^{\infty}\left(\sum_{i+j=k} f[i]g[j]\right)kt^{k-1}$$

Note that we may formally extend the sum to $k = 0$, as the 0-th summand is 0. Also note that we have the identity $kt^{k-1} = (i+j)t^{i+j-1} = it^{i+j-1} + jt^{i+j-1} = it^{i-1}\cdot t^j + t^i jt^{j-1} = (t^i)'\cdot t^j + t^i\cdot(t^j)'$ such that

we may continue our computation with the expression

$$\begin{aligned}
(f\cdot g)' &= \sum_{k=1}^{\infty}\left(\sum_{i+j=k} f[i]g[j]\right)\left((t^i)'\cdot t^j + t^i\cdot(t^j)'\right)\\
&= \sum_{k=0}^{\infty}\left(\sum_{i+j=k} f[i]g[j]\left((t^i)'\cdot t^j + t^i\cdot(t^j)'\right)\right)\\
&= \sum_{i=0}^{\infty}\sum_{j=0}^{\infty} f[i]g[j]\left((t^i)'\cdot t^j + t^i\cdot(t^j)'\right)\\
&= \sum_{i=0}^{\infty}\sum_{j=0}^{\infty} f[i](t^i)'g[j]t^j + \sum_{i=0}^{\infty}\sum_{j=0}^{\infty} f[i]t^i g[j](t^j)'\\
&= \left(\sum_{i=0}^{\infty} f[i](t^i)'\right)\cdot\left(\sum_{j=0}^{\infty} g[j]t^j\right) + \left(\sum_{i=0}^{\infty} f[i]t^i\right)\cdot\left(\sum_{j=0}^{\infty} g[j](t^j)'\right)\\
&= \left(\sum_{i=0}^{\infty} f[i]t^i\right)'\cdot\left(\sum_{j=0}^{\infty} g[j]t^j\right) + \left(\sum_{i=0}^{\infty} f[i]t^i\right)\cdot\left(\sum_{j=0}^{\infty} g[j]t^j\right)'\\
&= f'\cdot g + f\cdot g'
\end{aligned}$$

□

Proof of (7.73):

(i) As the partial derivatives are defined by linear expansion, it suffices to check the commutativity on the basis elements t^α for some $\alpha = (\alpha_1,\ldots,\alpha_n)\in\mathbb{N}$. If $i=j$, then $\partial_i\partial_j = \partial_j\partial_i$ is trivial. For $i\neq j$ we distinguish two cases: (1) If $\alpha_i = 0$ or $\alpha_j = 0$ then $\partial_i t^\alpha = 0$ or $\partial_j t^\alpha = 0$. In both cases we get $\partial_i\partial_j t^\alpha = 0$ and likewise $\partial_j\partial_i t^\alpha = 0$ respectively. (2) If $\alpha_i \geq 1$ and $\alpha_j \geq 1$ then it is easy to see, that $\partial_i\partial_j t^\alpha = \partial_i(\alpha_j t^{\alpha-\delta_j}) = \alpha_j\partial_i(t^{\alpha-\delta_j}) = \alpha_j\alpha_i t^{\alpha-\delta_j-\delta_j}$ and likewise $\partial_j\partial_i t^\alpha = \alpha_i\alpha_j t^{\alpha-\delta_i-\delta_j}$. In both cases (1) and (2) we see that $\partial_i\partial_j t^\alpha$ and $\partial_j\partial_i t^\alpha$ are equal and hence this is also true for any polynomial $f\in R[t_1,\ldots,t_n]$

$$\partial_i\partial_j f \;=\; \sum_{\alpha\in\mathbb{N}^n} f[\alpha]\,\partial_i\partial_j t^\alpha \;=\; \sum_{\alpha\in\mathbb{N}^n} f[\alpha]\,\partial_j\partial_i t^\alpha \;=\; \partial_j\partial_i f$$

(ii) Let us first consider the case $n=1$: For any $i,j\in\mathbb{N}$ we will prove $\partial^i t^j = (j!/(j-i)!)t^{j-i}$ by induction on i: As $\partial^0 = \mathbb{1}$ the statement is true for $i=0$. And for $i=1$ we have $\partial^i = \partial$ such that $\partial t^j = jt^{j-1} = (j!/(j-1)!)t^{j-i}$ [and $\partial t^j = 0$ for $j=0$] is just the definition of the formal derivative ∂. Now for the induction step $i-1\mapsto i$ we use this definition once more

$$\partial^i t^j \;=\; \partial\partial^{i-1}t^j \;=\; \partial\left(\frac{j!}{(j-i+1)!}t^{j-i+1}\right) \;=\; \frac{j!}{(j-i+1)!}(j-i+1)t^{j-i+1-1} \;=\; \frac{j!}{(j-i)!}t^{j-i}$$

in case $i\leq j$. If $i=j+1$ then we note that $\partial^j t^j = j!$ is of degree zero, such that $\partial^i t^j = \partial\partial^j t^j = 0$. And finally for $i>j+1$ we already have $\partial^{i-1}t^j = 0$ already, such that $\partial^i t^j = 0$ stays true. Altogether we have proved the claim in case $n=1$.

Let us now use induction on the number n of variables of the polynomial ring. The case $n=1$ has already been dealt with, so we commence with the induction step $n\mapsto n+1$: That is we have to take a look at $\alpha' = (\alpha,\alpha_{n+1})$ where $\alpha = (\alpha_1,\ldots,\alpha_n)$ and likewise the same for $\beta' = (\beta,\beta_{n+1})\in\mathbb{N}^{n+1}$.

Then we find the expression

$$\partial^{\alpha'} t^{\beta'} \;=\; \partial^{\alpha} \partial_{n+1}^{\alpha_{n+1}} t^{\beta} t_{n+1}^{\beta_{n+1}} \;=\; \partial^{\alpha} t^{\beta}\, \partial_{n+1}^{\alpha_{n+1}} t_{n+1}^{\beta_{n+1}}$$

where we already used, that ∂_{n+1} is $R[t_1,\ldots,t_n]$-linear. If $\beta_{n+1} > \alpha_{n+1}$ then $\partial_{n+1}^{\alpha_{n+1}} t_{n+1}^{\beta_{n+1}} = 0$ by the case $n = 1$. In this case the whole term vanishes. And if $\beta_{n+1} \leq \alpha_{n+1}$ then by $n = 1$ again

$$\partial^{\alpha} t^{\beta}\, \partial_{n+1}^{\alpha_{n+1}} t_{n+1}^{\beta_{n+1}} \;=\; \partial^{\alpha} t^{\beta} \frac{\beta_{n+1}!}{(\beta_{n+1}-\alpha_{n+1})!}\, t_{n+1}^{\beta_{n+1}-\alpha_{n+1}}$$

Now insert the induction hypothesis for $\partial^{\alpha} t^{\beta}$: This either is 0, if there is some $i \in 1\ldots n$ with $\alpha_i > \beta_i$ such that the whole term vanishes, again. Or, in case $\alpha_i \leq \beta_i$ we compute

$$\partial^{\alpha'} t^{\beta'} \;=\; \prod_{i=1}^{n} \frac{\beta_i!}{(\beta_i-\alpha_i)!}\, t_i^{\beta_i-\alpha_i} \frac{\beta_{n+1}!}{(\beta_{n+1}-\alpha_{n+1})!}\, t_{n+1}^{\beta_{n+1}-\alpha_{n+1}} \;=\; \frac{\beta'!}{(\beta'-\alpha')!}\, t^{\beta'-\alpha'}$$

(iii) By (i) $R[\partial_1,\ldots,\partial_n]$ is generated by mutually commutative elements and hence is a commutative algebra in itself. And clearly $\varepsilon : f \mapsto f(\partial_1,\ldots,\partial_n)$ is a surjective homomorphism from the polynomial ring $R[d_1,\ldots,d_n]$ to $R[\partial_1,\ldots,\partial_n]$. It suffices to check that $\mathrm{kn}(\varepsilon) = 0$, then ε is injective and hence an isomorphism. So consider any $f \in R[d_1,\ldots,d_n]$ such that $f \neq 0$, then we need to show $f(\partial_1,\ldots,\partial_n) \neq 0$. We do this by induction on n once more: In case $n = 1$ let $m := \deg(f)$ be the degree of $f \in R[d_1]$, in particular $f[m] \neq 0$. Let use (ii) to evaluate what $f(\partial_1)$ makes out of t_1^m:

$$f(\partial_1)(t_1^m) \;=\; \sum_{k=0}^{m} f[k]\, \partial_1^k t_1^m \;=\; \sum_{k=0}^{m} f[k] \frac{m!}{(m-k)!} t_1^{m-k}$$

In particular the constant coefficient of $f(\partial_1)(t_1^m)$ is assumed for $k = m$ and this is $f[m] \cdot m! \neq 0$, which is non-zero, as R is an integral domain. Thus we find $f(\partial_1)(t_1^m) \neq 0$ hence $f(\partial_1) \neq 0$. Now to the induction step $n \geq 2$: If we have $f \in R[t_2,\ldots,t_n]$ then we are done by induction hypothesis. Otherwise, if f depends on t_1 let $m := \deg_1(f)$ and write $f \in R[d_1,\ldots,d_n]$ as an element of $R[d_2,\ldots,d_n][d_1]$, that is we write f in the form

$$f(d_1,\ldots,d_n) \;=\; \sum_{k=0}^{m} f_k(d_2,\ldots,d_n)\, t_1^k$$

for some $f_k \in R[d_2,\ldots,d_n]$ with $f_d \neq 0$. What works out once, works out twice: As $f_d \neq 0$ the induction hypothesis yields $f_d(\partial_2,\ldots,\partial_n) \neq 0$, that is there is some $g \in R[t_2,\ldots,t_n]$ such that $f_d(\partial_2,\ldots,\partial_n)(g) \neq 0$. Now take a look at

$$f(\partial_1,\ldots,\partial_n)(g t_1^m) \;=\; \sum_{k=0}^{m} f_k(\partial_2,\ldots,\partial_n)\partial_1^k(g t_1^m) \;=\; \sum_{k=0}^{m} f_k(\partial_2,\ldots,\partial_n)(g) \frac{m!}{(m-k)!} t_1^{m-k}$$

Again the constant term in t_1 is assumed for $k = m$ and is given to be $f(\partial_2,\ldots,\partial_2)(g) \cdot m!$. But $R[d_2,\ldots,d_n]$ is an integral domain, too and hence the constant term in t_1 of $f(\partial_1,\ldots,\partial_n)(g t_1^m)$ is non-zero. In particular $f(\partial_1,\ldots,\partial_n)(g t_1^m)$ cannot be zero and hence $f(\partial_1,\ldots,\partial_n) \neq 0$.

(iv) Let us first prove the chain rule for monomials $g(t) = t^{\alpha}$ where $\alpha = (\alpha_1,\ldots,\alpha_n)$. Let us also

abbreviate $f = (f_1, \ldots, f_n) \in R[t_1, \ldots, t_n]^n$. As $\partial/\partial s_i$ is a derivation we can use (7.70) to get

$$\begin{aligned}\frac{\partial}{\partial s_i} g(f) &= \frac{\partial}{\partial s_i} f^\alpha = \frac{\partial}{\partial s_i}\left(\prod_{j=1}^n f_j^{\alpha_j}\right) \\ &= \sum_{j=1}^n \frac{\partial}{\partial s_i}\left(f_j^{\alpha_j}\right) \cdot \prod_{k\neq j}^n f_k^{\alpha_k} \\ &= \sum_{j=1}^n \alpha_j \frac{\partial f_j}{\partial s_i} \cdot f_j^{\alpha_j - 1} \cdot \prod_{k\neq j}^n f_j^{\alpha_j}\end{aligned}$$

Now note that $\partial g/\partial t_j = \alpha_j t_j^{\alpha_j - 1} \prod_k t_k^{\alpha_k}$ where the sum runs over $k \in \{1, \ldots, n\} \setminus \{j\}$. That is we recognize that $\partial g/\partial t_j(f)$ is part of the expression above, in fact we see

$$\frac{\partial}{\partial s_i} g(f) = \sum_{j=1}^n \frac{\partial f_j}{\partial s_i} \cdot \frac{\partial g}{\partial t_j}(f)$$

That is, we have proved the claim for any monomial $g(t) = t^\alpha$. Also note that in case $\alpha_j = 0$ both, the formal derivative $\partial/\partial t_j$ and the summand containing α_j vanish and hence we did not bother to distinguish cases, even though $f_j^{\alpha_j - 1}$ is not well-defined, in this case. So it remains to verify the identity for arbitrary $g \in R[t_1, \ldots, t_n]$, but by R-linearity this can be reduced to the case of moninomials, using the following computation

$$\begin{aligned}\frac{\partial}{\partial s_i} g(f) &= \frac{\partial}{\partial s_i}\left(\sum_{\alpha\in\mathbb{N}^n} g[\alpha]\, f^\alpha\right) \\ &= \sum_{\alpha\in\mathbb{N}^n} g[\alpha]\, \frac{\partial}{\partial s_i}(f^\alpha) \\ &= \sum_{\alpha\in\mathbb{N}^n} g[\alpha] \sum_{j=1}^n \frac{\partial f_j}{\partial s_i} \cdot \frac{\partial t^\alpha}{\partial t_j}(f) \\ &= \sum_{j=1}^n \frac{\partial f_j}{\partial s_i} \cdot \left(\sum_{\alpha\in\mathbb{N}^n} g[\alpha] \frac{\partial t^\alpha}{\partial t_j}\right)(f) \\ &= \sum_{j=1}^n \frac{\partial f_j}{\partial s_i} \cdot \frac{\partial g}{\partial t_j}(f)\end{aligned}$$

(v) Let us first check the Taylor expansion for $x = 0$: Let us abbreviate $\forall\, i \in 1 \ldots n : \alpha_i \leq \beta_i$ by $\alpha \leq \beta$, then according to (ii) we have $\partial^\alpha t^\beta = 0$ for any β for which $\alpha \leq \beta$ is untrue. And for $\alpha \leq \beta$ we can use the formula for $\partial^\alpha t^\beta$ in (ii) and compute

$$\partial^\alpha f = \sum_{\beta\in\mathbb{N}^n} f[\beta]\,(\partial^\alpha t^\beta) = \sum_{\beta\geq\alpha} f[\beta]\, \frac{\beta!}{(\beta-\alpha)!}\, t^{\beta-\alpha}$$

From this we find $(\partial^\alpha f)(0) = \alpha! f[\alpha]$ as $\beta = \alpha$ is the only constant term in the expression for $\partial^\alpha f$. In particular we can write out f in the following way

$$f = \sum_{\alpha\in\mathbb{N}^n} f[\alpha]\, t^\alpha = \sum_{\alpha\in\mathbb{N}^n} \frac{1}{\alpha!}(\alpha! f[\alpha]) t^\alpha = \sum_{\alpha\in\mathbb{N}^n} \frac{1}{\alpha!}(\partial^\alpha f)(0)\, t^\alpha$$

For a general polynomial $f \in R[t_1,\dots,t_n]$ we use the automorphism $f(t) \mapsto f(t+x)$ on $R[t_1,\dots,t_n]$. If we take $g(t) := f(t+x)$ we can expand g at the point $x = 0$, that is

$$g(t) \;=\; \sum_{\alpha\in\mathbb{N}^n} \frac{1}{\alpha!}\big(\partial^\alpha g\big)(0)\, t^\alpha$$

By construction we have $f(t) = g(t-x)$ and hence can evaluate $f(t)$ in terms of the expansion of g at $x = 0$. Applying the inverse automorphism $g \mapsto g(t-x)$ we find

$$f(t) \;=\; g(t-x) \;=\; \sum_{\alpha\in\mathbb{N}^n} \frac{1}{\alpha!}\big(\partial^\alpha g\big)(0)\,(t-x)^\alpha$$

We need to take control of $(\partial^\alpha g)(0)$, still. So we use the chain rule (iv) with the parameters $g := f$, $f_j := t_j + x_j$ and $s_i := t_i$: Then we get the identifications $\partial g/\partial s_i(f)$ becomes $\partial_i f(t+x) = \partial_i g$ and $\partial f_j/\partial s_i$ becomes $\partial_i(t_j + x_j) = \delta_{i,j}$ and $\partial g/\partial t_j$ becomes $\partial_j f$ such that

$$(\partial_i g)(t) \;=\; \sum_{j=1}^{n} \delta_{i,j}(\partial_j f)(t+x) \;=\; (\partial_i f)(t+x)$$

By induction we find $(\partial^\alpha g)(t) = (\partial^\alpha f)(t+x)$ for any $\alpha \in \mathbb{N}^n$. And evaluating this identity at $t = x$ we get $(\partial^\alpha g)(0) = (\partial^\alpha f)(x)$ and thereby the general Taylor expansion

$$f(t) \;=\; \sum_{\alpha\in\mathbb{N}^n} \frac{1}{\alpha!}\big(\partial^\alpha f\big)(x)\,(t-x)^\alpha$$

□

Proof of (7.32):

(i) Let us regard the truncation homomorphism $\varrho : R[\![\varepsilon]\!] \twoheadrightarrow R[\![\varepsilon]\!]/\varepsilon^{l+1}R[\![\varepsilon]\!]$, where for any $a \in R[\![\varepsilon]\!]$ this is defined by $\varrho(a) := a + \varepsilon^{l+1}R[\![\varepsilon]\!]$. By assumption we have $\varrho(a_i) = \varrho(b_i)$ for any $i \in 1\dots n$ and hence for any polynomial $f \in R[t_1,\dots,t_n]$

$$\varrho(f(b_1,\dots,b_n)) \;=\; f(\varrho(b_1),\dots,\varrho(b_n)) \;=\; f(\varrho(a_1),\dots,\varrho(a_n)) \;=\; \varrho(f(a_1,\dots,a_n))$$

as ϱ commutes with additions and multiplications. Yet by construction of ϱ this means that for any $k \in 0\dots l$ we have $f(b_1,\dots,b_n)[k] = f(a_1,\dots,a_n)[k]$, as we had claimed.

(ii) We will first prove the identity of $f(a)$ which basically is a straightforward computation. Let us just write down what $f(a)$ means explicitly

$$f(a) \;=\; \sum_{\alpha\in\mathbb{N}^n} f[\alpha]\, a^\alpha \;=\; \sum_{\alpha\in\mathbb{N}^n} f[\alpha] \prod_{i=1}^{n} a_i^{\alpha_i}$$

Let us first consider polynomials $a_i \in R[\varepsilon]$ only and choose an $l \in \mathbb{N}$ such that $\deg(a_i) \le l$ for all $i \in 1\dots n$. Then we can write $a_i = a_i[0] + a_i[1]\varepsilon + \dots + a_i[l]\varepsilon^l$ and the polynomial rule (also called general binomial theorem) (1.41) yields the identity

$$a_i^{\alpha_i} \;=\; \big(a_i[l]\varepsilon^l + \dots + a_i[1]\varepsilon + a_i[0]\big)^{\alpha_i}$$

$$
\begin{aligned}
&= \sum_{|\beta_i|=\alpha_i} \binom{\alpha_i}{\beta_i} \prod_{k=0}^{l} \left(a_i[k]\varepsilon^k\right)^{\beta_{i,k}} \\
&= \sum_{|\beta_i|=\alpha_i} \binom{\alpha_i}{\beta_i} \left(\prod_{k=0}^{l} a_i[k]^{\beta_{i,k}}\right) \left(\prod_{k=0}^{l} \varepsilon^{k\cdot\beta_{i,k}}\right) \\
&= \sum_{|\beta_i|=\alpha_i} \binom{\alpha_i}{\beta_i} \dot{a}_i^{\beta_i} \varepsilon^{\|\beta_i\|}
\end{aligned}
$$

where we denoted $\dot{a}_i := (a_i[0], a_i[1], \ldots, a_i[l]) \in R^{l+1}$ the summation runs over all multi-indices $\beta_i = (\beta_{i,0}, \ldots, \beta_{i,l}) \in \mathbb{N}^{l+1}$ with $|\beta_i| = \beta_{i,0} + \cdots + \beta_{i,l} = \alpha_i$ and $\|\beta_i\| := 1 \cdot \beta_{i,1} + 2 \cdot \beta_{i,2} + \cdots + l \cdot \beta_{i,l}$. Inserting this identity into our expression for $f(a)$ we find

$$
f(a) \;=\; \sum_{\alpha\in\mathbb{N}^n} f[\alpha] \prod_{i=1}^{n} \sum_{|\beta_i|=\alpha_i} \binom{\alpha_i}{\beta_i} \dot{a}_i^{\beta_i} \varepsilon^{\|\beta_i\|}
$$

We refer to (1.41) again, where we have seen, that in arbitrary commutative rings R, for arbitrary elements $r_{i,\beta_i} \in R$ and any finite index sets B_i (where $i \in 1 \ldots n$) summation and multiplication can be interchanged in the following way

$$
\prod_{i=1}^{n} \sum_{\beta_i\in B_i} r_{i,\beta_i} \;=\; \sum_{\beta\in B_1\times\cdots\times B_n} \prod_{i=1}^{n} r_{i,\beta_i}
$$

In our case we have $B_i = \{\, \beta_i \in B \mid |\beta_i| = \alpha_i \,\}$ where $B := \mathbb{N}^{l+1}$ and hence the product is given to be $B(\alpha) := B_1 \times \cdots \times B_n = \{\, \beta \in B \mid |\beta| = \alpha \,\}$, such that we arrive at

$$
f(a) \;=\; \sum_{\alpha\in\mathbb{N}^n} f[\alpha] \sum_{\beta\in B(\alpha)} \prod_{i=1}^{n} \binom{\alpha_i}{\beta_i} a_i^{\beta_i} \varepsilon^{\|\beta_i\|}
$$

Contracting the product (over i) the binomial coefficients (α_i over β_i) multiply up to (α over β), the $(\dot{a}_i)^{\beta_i}$ multiply up to $(\dot{a})^{\beta}$ and the $\varepsilon^{\|\beta_i\|}$ multiply up to $\varepsilon^{\|\beta\|}$. Altogether we find that

$$
\begin{aligned}
f(a) \;&=\; \sum_{\alpha\in\mathbb{N}^n} f[\alpha] \sum_{\beta\in B(\alpha)} \binom{\alpha}{\beta} \dot{a}^{\beta} \varepsilon^{\|\beta\|} \\
&=\; \sum_{k=0}^{\infty} \left(\sum_{\alpha\in\mathbb{N}^n} \sum_{\beta\in B(\alpha,k)} \binom{\alpha}{\beta} f[\alpha]\, \dot{a}^{\beta} \right) \varepsilon^k \\
&=\; \sum_{k=0}^{\infty} \mathcal{L}_k(f)(\dot{a})\, \varepsilon^k
\end{aligned}
$$

That is we have proved the claim for polynomials $a_i \in R[\varepsilon]$. For general power series $a_i \in R[\![\varepsilon]\!]$ consider any $k \in \mathbb{N}$, all we have to prove is $f(a_1, \ldots, a_n)[k] = \mathcal{L}_k(f)(\dot{a})$. Yet by (i) we know that for $f(a_1, \ldots, a_n)[k]$ the coefficients $a_i[j]$ with $j > k$ are irrelevant. That is we may take to $b_i := a_i[0] + a_i[1]\varepsilon + \cdots + a_i[k]\varepsilon^k \in R[\varepsilon]$ instead. And for these polynomials we have just seen

$$
\begin{aligned}
f(a_1, \ldots, a_n)[k] \;&=\; f(b_1, \ldots, b_n)[k] \;=\; \mathcal{L}_k(f)(b[0], \ldots, b[k]) \\
&=\; \mathcal{L}_k(f)(a[0], \ldots, a[k]) \;=\; \mathcal{L}_k(f)(a[0], a[1], a[2], \ldots)
\end{aligned}
$$

(iii) Append R to a polynomial ring in the variable symbols $t_{r,s}$ where $r \in 1 \dots n$ and $s \in 0 \dots l$ and consider $a_r := t_{r,0} + t_{r,1}\varepsilon + \cdots + t_{r,l}\varepsilon^l \in R[\![\varepsilon]\!]$. Then by (ii) we have

$$f(a_1, \dots, a_n)(\varepsilon) \;=\; \sum_{k=0}^{\infty} \mathcal{L}_k(f)(a[0], \dots, a[l])\, \varepsilon^k$$

where as usual we took $a[k] := (a_1[k], \dots, a_n[k]) = (t_{1,k}, \dots, t_{n,k}) \in R^n$. Then by construction of the a_r we have $\mathcal{L}_k(f)(a[0], \dots, a[l]) = \mathcal{L}_k(f)$ and hence

$$\big(f \cdot g\big)(a_1, \dots, a_n) \;=\; \sum_{k=0}^{\infty} \mathcal{L}_k(f \cdot g)\, \varepsilon^k$$

But the evaluation of polynomials is a homomorphism, such that we may use the multiplicativity to split $(fg)(a_1, \dots, a_n)$ and evaluate separately

$$\begin{aligned}
& \big(f \cdot g\big)(a_1, \dots, a_n) \\
= \;& f(a_1, \dots, a_n) \cdot g(a_1, \dots, a_n) \\
= \;& \left(\sum_{i=0}^{\infty} \mathcal{L}_i(f)\, \varepsilon^i \right) \cdot \left(\sum_{j=0}^{\infty} \mathcal{L}_j(f)\, \varepsilon^j \right) \\
= \;& \sum_{k=0}^{\infty} \left(\sum_{i+j=k} \mathcal{L}_i(f) \cdot \mathcal{L}_j(g) \right) \varepsilon^k
\end{aligned}$$

Comparing the coefficients of ε^k we find the multiplicative identity of the claim. And the R-linearity is clear, as $\mathcal{L}_k$ has been defined by linear expansion of

$$t^\alpha \;\mapsto\; \sum_{\beta \in B(\alpha,k)} \binom{\alpha}{\beta}\, t^\beta$$

(iv) Consider any $\beta = (\beta_1, \dots, \beta_n) \in B(\alpha, l)$ and suppose t^β contains some factor of the form $t_{p,l}$ for some $p \in 1 \dots n$. As $t_{p,l}$ divides t^β we have $\beta_{p,l} \geq 1$ and hence $l = \|\beta\| \geq l \cdot \beta_{p,l} \geq l$. This implies $\beta_{p,l} = 1$ and we will argue below, that thereby β is of the form:

$$\begin{aligned}
\beta_i &= (\alpha_i, 0, 0, \dots) \text{ for any } i \neq p \text{ and} \\
\beta_p &= (\alpha_p - 1, 0, \dots, 0, 1, 0, \dots)
\end{aligned}$$

- If $j \notin \{1, l\}$ then $\beta_{p,j} = 0$, as any $\beta_{p,j} \geq 1$ would contribute $j \cdot \beta_{p,j}$ to $\|\beta\|$ and this already is at l, due to $l \cdot \beta_{p,l}$.
- $\beta_{p,0} \;=\; \alpha_i - 1$, as $|\beta_p| = \alpha_p$ and all the other $\beta_{p,j}$ have already been ruled out.
- If $i \neq p$ then $\beta_i \;=\; (\alpha_i, 0, \dots)$, as for any $j \geq 1$ any $\beta_{i,j} \geq 1$ would contribute $j \cdot \beta_{i,j}$ to $\|\beta\|$ and this already is at l, due to $l \cdot \beta_{p,l}$.

In particular we find (α_p over β_p) equals α_p and for $i \neq p$ we have (α_i over β_i) equals 1 instead. Combining this we get (α over β) equals α_p. Let us now split $B(\alpha, l)$ into two subsets

$$B'(\alpha, l) \;:=\; \Big\{ \beta \in B(\alpha, l) \mid \exists\, p \in 1 \dots n \,:\, t_{p,l} \mid t^\beta \Big\}$$

$$B''(\alpha,l) \;:=\; \Big\{\, \beta \in B(\alpha,l) \mid \forall\, p \in 1\dots n \,:\, t_{p,l} \not| \, t^\beta \,\Big\}$$

Now consider $f(\overline{a})[l]$, by (ii) this is $\mathcal{L}_l(f)(\dot{a})$ and we can split this term according to the disjoint union $B(\alpha,l) = B'(\alpha,l) \cup B''(\alpha,l)$ (where $\dot{a} = (a[0],\dots,a[l],0,\dots)$)

$$\mathcal{L}_l(f)(\dot{a}) \;=\; \underbrace{\sum_{\alpha\in\mathbb{N}^n} \sum_{\beta\in B'(\alpha,l)} \binom{\alpha}{\beta} f[\alpha]\, \dot{a}^\beta}_{\text{lead}} + \underbrace{\sum_{\alpha\in\mathbb{N}^n} \sum_{\beta\in B''(\alpha,l)} \binom{\alpha}{\beta} f[\alpha]\, \dot{a}^\beta}_{\text{rest}}$$

By what we have argued above, at the beginning of our proof ov (iv), $B'(\alpha,l)$ has exactly n elements that are determined by $\beta_p[l] = 1$ each, hence we get

$$\begin{aligned}
\text{lead} \;&=\; \sum_{\alpha\in\mathbb{N}^n} \sum_{p=1}^{n} \alpha_p f[\alpha]\, a_p[0]^{\alpha_p - 1} a_p[l] \prod_{i\neq p} a_i[0]^{\alpha_i} \\
&=\; \sum_{\alpha\in\mathbb{N}^n} f[\alpha] \sum_{p=1}^{n} \left(\partial_p \prod_{i=1}^{n} t_i^{\alpha_i} \right) (a[0]) \cdot a_p[l] \\
&=\; \sum_{p=1}^{n} \left(\partial_p \sum_{\alpha\in\mathbb{N}^n} f[\alpha]\, t^\alpha \right) (a[0]) \cdot a_p[l] \\
&=\; \sum_{p=1}^{n} (\partial_p f)(a[0]) \cdot a_p[l]
\end{aligned}$$

The rest does not contain any of the monomials $t_{i,l}$ and hence is independent of $a[l]$ and all higher orders $a[l+1],\dots$. That is we can arbitrarily change $a[l]$ without changing its value. In particular we may choose $a[l] = 0$, but if $a[l] = 0$ then any $\beta \in B'(\alpha,l)$ makes $\dot{a}^\beta = 0$ vanish, such that lead vanishes and only the rest remains

$$\text{rest} \;=\; \mathcal{L}_l(f)(a[0],\dots,a[l-1],0,0,\dots) \;=\; f(a)[l]$$

□

Proof of (7.75):

(i) *Uniqueness:* Suppose we have some $x \in \mathbb{R}$, such that $x^2 = r$. Then we can use this x to decompose $f(t) := t^2 - r \in \mathbb{R}[t]$ into $f(t) = t^2 - x^2 = (t+x)(t-x)$. Suppose $y > 0$ was another real number satisfying $y^2 = r$, then this would mean $f(y) = 0$ and thereby $t - y \mid f = (t+x)(t-x)$. But as $\mathbb{R}$ is a field, $\mathbb{R}[t]$ is an UFD and $t-y$, $t+x$ and $t-x$ all are prime, as they are of degree 1. Thus we have $t - y = t + x$ or $t - y = t - x$. The first would mean $y = -x$, but as $x > 0$ we have $-x < 0 < y$, so this is ruled out. So we are stuck with $t - y = t - x$ which means $x = y$, which is the uniqueness of the square root $x = \sqrt{r}$.

- *Monotony:* Consider real numbers $x, y \in \mathbb{R}$ such that $0 < x < y$. Multiplying this inequality with $x \geq 0$ we get $x^2 \leq xy$. And multiplying this inequality with $y \geq 0$ we get $xy \leq y^2$ which combines to $x^2 \leq y^2$. Now $x^2 = y^2$ would mean $x = y$, by uniqueness above. From this we conclude $x^2 < y^2$. Altogether we have found

$$0 < x < y \quad\Longrightarrow\quad x^2 < y^2$$

- *Convergence:* This proof uses some properties of the reals, that are best left to a course in numbers or analysis: Let us first prove, that for any $n \geq 0$ we have $0 < r \leq a_{n+1}^2$: To do this we simply employ the recursion formula and compute

$$a_{n+1}^2 - r \;=\; \frac{1}{4}\left(a_n + \frac{r}{a_n}\right)^2 - r \;=\; \left(a_n^2 + 2r + \frac{r^2}{a_n^2} - 4r\right)^2 \;=\; \frac{1}{4}\left(a_n - \frac{r}{a_n}\right)^2 \;\geq\; 0$$

Next we will prove that for any $1 \leq n \in \mathbb{N}$ we get $a_{n+1} < a_n$ by computing

$$a_n - a_{n+1} \;=\; a_n - \frac{1}{2}\left(a_n + \frac{r}{a_n}\right) \;=\; \frac{1}{2}\left(a_n - \frac{r}{a_n}\right) \;=\; \frac{a_n^2 - r}{2a_n} \;\geq\; 0$$

As we have seen $a_n^2 > r$ for any $n \geq 1$ we conclude $a_n - a_{n+1} \geq 0$ such that $r \leq a_{n+1} \leq a_n$. That is (a_n) is monotonously decreasing and bounded from below. In $\mathbb{R}$ this implies that (a_n) converges. Let $x \in \mathbb{R}$ be the limit of (a_n), then we have to prove $x^2 = r$. As $0 < r \leq (a_n)$ we have $0 < r \leq x$ and as $x \neq 0$ we may compute

$$x \;=\; \lim_{n\to\infty} a_n \;=\; \lim_{n\to\infty} a_{n+1} \;=\; \lim_{n\to\infty} \frac{1}{2}\left(a_n + \frac{r}{a_n}\right) \;=\; \frac{1}{2}\left(x + \frac{r}{x}\right)$$

Multiplying this equation by $2x$ we get $2x^2 = x^2 + r$ which turns into $x^2 = r$. By construction any a_n is contained in $\mathbb{Q}$, that is we have found a sequence in $\mathbb{Q}$, that converges and hence is a Cauchy-sequence. As $\mathbb{R}$ is complete, this means $x = (a_n) + \mathfrak{z}$ is a real number.

(ii) As $z \neq 0$ we have $r > 0$ and thereby (i) tells us there is a uniquely determined $x > 0$ with $x^2 = r$. This x is denoted by $x = \sqrt{r}$. In the following computation we make use of the *angle sum formula* (■) that are elementary to prove, but which we leave to standard textbooks on analysis

$$\begin{aligned} & \left(\pm\sqrt{r}\left(\cos\left(\frac{\alpha}{2}\right) + i \cdot \sin\left(\frac{\alpha}{2}\right)\right)\right)^2 \\ = \;& \sqrt{r}^2\left(\cos\left(\frac{\alpha}{2}\right)^2 - \sin\left(\frac{\alpha}{2}\right)\right) + 2i\sin\left(\frac{\alpha}{2}\right)\cos\left(\frac{\alpha}{2}\right) \\ = \;& r\left(\cos\left(\frac{\alpha}{2} + \frac{\alpha}{2}\right) + i\sin\left(\frac{\alpha}{2} + \frac{\alpha}{2}\right)\right) \;=\; z \end{aligned}$$

That is we have $w_1^2 = z$ and $w_2^2 = z$. Suppose we had $w_1 = w_2$, as also $w_1 = -w_2$ this would imply $w_2 = -w_2$ such that $2w_2 = 0$. But as $r > 0$ we have $w_2 \neq 0$ and thereby $2w_2 \neq 0$. Hence $w_1 \neq w_2$ are distinct. Thus the polynomial $f(t) := t^2 - z$ has the roots $\mathbb{V}(f) = \{w_1, w_2\}$. As $\mathbb{C}$ is an integral domain (even a field) the number of roots cannot exceed the degree of f, thus w_1 and w_2 are the only solutions of $w^2 = z$ - that is they are uniquely determined.

□

Proof of (7.76):

- We will evade the ordeal of proving all the properties of a commutative ring of $R[\sqrt{s}]$ by proving the first isomorphy: As always R^2 becomes an R-module under the operations $(a,b) + (c,d) = (a+c, b+d)$ and $a(c,d) = (ac, ad)$. And $R[t]/\mathfrak{w}$ becomes an R-module under the operations $(a + bt + \mathfrak{w}) + (c + dt + \mathfrak{w}) = (a+c) + (b+d)t + \mathfrak{w}$ and $a(c + dt + \mathfrak{w}) = ac + adt + \mathfrak{w}$. From

this it is clear, that the following map is a well-defined and R-linear

$$\Phi \,:\, R[\sqrt{s}] \,\to\, {R[t]}\Big/_{\mathfrak{w}} \,:\, (a,b) \,\mapsto\, a+tb+\mathfrak{w}$$

We will show, that this map is bijective, starting with the surjectivity: That is we consider any polynomial $f \in R[t]$ and need to find a, $b \in R$, such that $a+bt+\mathfrak{w} = f+\mathfrak{w}$. To do this we use the identity $t^2+\mathfrak{w} = s+\mathfrak{w}$ and split f into its odd and even powers

$$\begin{aligned} f+\mathfrak{w} \;&=\; \sum_{n=0}^{\infty} f[n]\,t^n + \mathfrak{w} \;=\; \sum_{j=0}^{\infty} f[2j]\,t^{2j} + t\cdot\sum_{k=0}^{\infty} f[2k+1]\,t^{2k} + \mathfrak{w} \\ &=\; \underbrace{\sum_{j=0}^{\infty} f[2j]\,s^j}_{a} + t\cdot\underbrace{\sum_{k=0}^{\infty} f[2k+1]\,s^k}_{b} + \mathfrak{w} \end{aligned}$$

Thus if we take a and b as indicated above, we found $\Phi(a+b\omega) = f+\mathfrak{w}$ which is the surjectivity of the map Φ. Let us turn our attention to the injectivity: For this we consider $\Phi(a+b\omega) = 0$ which is $a+bt \in \mathfrak{w} = (t^2-s)R[t]$. That is there is some polynomial $f \in R[t]$ such that

$$a+tb \;=\; (t^2-s)f \;=\; \sum_{k=2}^{\infty} f[k-2]\,t^k - \sum_{k=0}^{\infty} sf[k]\,t^k$$

Comparing the degree 0 and 1 coefficients, we get $a = -sf[0]$ and $b = -sf[1]$ respectively. For the k-th coefficient, where $k \geq 2$ we find $0 = f[k-2] - sf[k]$, that is $sf[k] = f[k-2]$. In other words $sf[2] = f[0]$, $sf[3] = f[1]$, $sf[4] = f[2]$ and so on. Inductively we see $s^k f[2k] = f[0]$ and $s^k f[2k+1] = f[1]$ for any $k \in \mathbb{N}$. Multiplying these equations with $-s$ we find

$$-s^{k+1}f[2k] \;=\; a \quad\text{and}\quad -s^{k+1}f[2k+1] \;=\; b$$

As f is a polynomial, we may take $k > \deg(f)/2$ to find $f[2k] = 0$ and $f[2k+1] = 0$ from which we get $a = 0$ and $b = 0$. That is $a+b\omega = 0$ and this also implies the injectivity of Φ. Altogether Φ is an isomorphism of R-modules.

- We now use this isomorphism compare the multiplication of $R[\sqrt{s}]$ and $R[t]/\mathfrak{w}$. The multiplication of $R[\sqrt{s}]$ is given to be $(a+b\omega)(c+d\omega) = (ac+bds)+(ad+bc)\omega$. And if we take a look at the multiplication of $R[t]/\mathfrak{w}$ we find

$$\big(a+tb+\mathfrak{w}\big)\big(c+dt+\mathfrak{w}\big) \;=\; ac+\big(ad+bc\big)t+bdt^2+\mathfrak{w} \;=\; \big(ac+dbs\big)+\big(ad+bc\big)t+\mathfrak{w}$$

That is $(a+b\omega)(c+d\omega)$ is mapped to $(a+tb+\mathfrak{w})(c+dt+\mathfrak{w})$ under Φ. That is Φ not only is R-linear and bijective, but respects the multiplication, as well. In particular Φ links the unit elements $1 = (1,0) \mapsto 1+\omega$. Thus $R[\sqrt{s}]$ inherits all the properties (associativity, commutativity and distributivity) of the multiplication from $R[t]/\mathfrak{w}$ and thereby is an R-algebra.

- Clearly $(a+b\omega)(a-b\omega) = a^2-b^2\omega^2 = a^2-sb^2$. Suppose $u := a^2-sb^2 \in R^*$ is a unit of R,

then combining these properties, we find

$$(a+b\omega)\Big(u^{-1}(a-b\omega)\Big) \;=\; (a+b\omega)(a-b\omega)u^{-1} \;=\; uu^{-1} \;=\; 1$$

Thus we find that $u = a^2 - sb^2 \in R^*$ implies $a+b\omega$ to be a unit of $R[\sqrt{s}]$, with inverse element $u^{-1}(a-b\omega)$. Conversely suppose $a+b\omega$ is a unit, that is there is some $c+d\omega \in R[\sqrt{s}]$ such that

$$1 \;=\; (a+b\omega)(c+d\omega) \;=\; (ac+dbs) + (ad+bc)\omega$$

That is we have $ac+dbs = 1$ and $ad+bc = 0$. Let again $u := a^2 - sb^2 \in R$, if we multiply the equation $1 = (a+b\omega)(c+d\omega)$ by $a-b\omega$, then we get

$$a - b\omega \;=\; (a-b\omega)(a+b\omega)(c+d\omega) \;=\; u(c+d\omega)$$

That is we have $a = uc$ and $b = -ud$. Multiplying the first equation with c and the second with ds we find $ac = uc^2$ and $bds = -ud^2s$ such that $1 = ac+bds = uc^2 - ud^2s = u(c^2 - ud^2)$. From this we find that $u \in R$ is a unit of R. That is we also have the inclusion of $R[\sqrt{s}]^*$ into $\{\, a+b\omega \mid a^2 - sb^2 \,\}$ and hence these sets are equal.

- It remains to verify the embedding of $R[\sqrt{s}] = \{\, a+b\omega \mid a,b \in R \,\}$ into the ring of 2×2-matrices over R. It is clear that the map given in the claim is well-defined and injective. Also - as the addition and scalar multiplication on R^2 and $\mathrm{mat}_2(R)$ are component-wise - this map is R-linear and $1 = 1+0\omega \mapsto \mathbb{1}_2$ is trivial. So it only remains to verify its multiplicativity: Let us compute

$$\begin{pmatrix} a & b \\ sb & a \end{pmatrix}\begin{pmatrix} c & d \\ sd & c \end{pmatrix} \;=\; \begin{pmatrix} ac+sbd & ad+bc \\ sbc+sad & sbd+ac \end{pmatrix}$$

 We see that the product matrix is precisely the image of $(ac+sbd)+(ad+bc)\omega = (a+b\omega)(c+d\omega)$, which is the multiplicativity we were looking for.

□

Proof of (7.77):
First note that $2^2 = (1+1)(1+1) = 1+1+1+1 = 4$ in general rings. Then the identity $at^2+bt+c = a(t+b/2a)^2 - \Delta/4a$ is straightforward to see. All we have to do is evaluate the binomial and recall $\Delta = b^2 - 4ac$. This is all due to the commutativity of the base ring R

$$a\left(t+\frac{b}{2a}\right)^2 - \frac{\Delta}{4a} \;=\; a\left(t^2+\frac{b}{a}t+\frac{b^2}{4a^2}\right)^2 - \frac{\Delta}{4a} \;=\; at^2+bt+\frac{b^2}{4a} - \frac{b^2-4ac}{4a} \;=\; at^2+bt+c$$

Now, suppose f had a root $x \in R$, that is $f(x) = 0$. Then this would imply $\Delta/4a = a(x^2+b/2a)^2$. Multiplying this equation by $4a$ it would turn into an expression that is a square in R

$$\Delta \;=\; 4a^2\left(x+\frac{b}{2a}\right)^2 \;=\; (2a)^2\left(x+\frac{b}{2a}\right)^2 \;\in\; R^\square$$

Conversely suppose $\Delta = \omega^2 \in R^\square$ is a square in R, then we can use the vertex form of f to turn it into

a product of two linear factors. The factor form of f is obvious from the following identity

$$\frac{f(t)}{a} \;=\; \left(t+\frac{b}{2a}\right)^2 - \frac{\Delta}{4a^2} \;=\; \left(t+\frac{b}{2a}\right)^2 - \left(\frac{\omega}{2a}\right)^2 \;=\; \left(t+\frac{b}{2a}+\frac{\omega}{2a}\right)\left(t+\frac{b}{2a}-\frac{\omega}{2a}\right)$$

In particular $\Delta \in R^\square$ is equivalent to f having roots in R. If R is an integral domain, then f can have at most $\deg(f) = 2$ roots, because of (7.54.(iv)). And if $\Delta = \omega^2$ for some $\omega \neq 0$ we already see two distinct roots, given in the claim of $\mathbb{V}(f)$, in the factor form of f

$$f(t) \;=\; a\left(t-\frac{-b-\omega}{2a}\right)\left(t-\frac{-b+\omega}{2a}\right)$$

And if $\Delta = 0$, then the vertex form tells us $f = a(t+b/2a)^2$. Now consider any root $x \in R$ of f, that is $0 = (x+b/2a)^2$. If R is an integral domain, then we conclude $x = -b/2a$. That is the root of f is uniquely determined to be $-b/2a$ which is the above formula for $\omega = 0$. □

Proof of (7.79):

(i) If $z = a+ib \in \mathbb{C}$ is any complex number, then $\overline{z} = a-ib$ by definition. Thus we see $z+\overline{z} = 2a \in \mathbb{R}$ and $z\overline{z} = (a+ib)(a-ib) = a^2-(ib)^2 = a^2+b^2 \in \mathbb{R}$. Now let $n := \deg(f)$, then from this it is obvious, that

$$f+\overline{f} \;=\; \sum_{k=0}^{n} f[k]\,t^k + \sum_{k=0}^{n} \overline{f[k]}\,t^k \;=\; \sum_{k=0}^{n} \Big(f[k]+\overline{f[k]}\Big)\,t^k \;\in\; \mathbb{R}[t]$$

Now consider $w = u+iv \in \mathbb{C}$, then $(a-ib)(u-iv) = (au-bv)-i(av+bu)$, that is $\overline{w\cdot z} = \overline{w}\cdot\overline{z}$. In particular we get $\overline{z^k} = \overline{z}^k$ for any $k \in \mathbb{N}$. And with this we are able to compute

$$f(\overline{z}) \;=\; \sum_{k=0}^{n} f[k]\,\overline{z}^k \;=\; \sum_{k=0}^{n} \overline{\overline{f[k]}}\,\overline{z^k} \;=\; \overline{\sum_{k=0}^{n} \overline{f[k]}\,z^k} \;=\; \overline{\overline{f}(z)}$$

Conjugating this identity again, we get $\overline{f(\overline{z})} = \overline{f}(z)$, as claimed. Let us finally prove $f\overline{f} \in setR[t]$, by induction on n: If $f = 0$, then $f\overline{f} = 0$, too, such that there is nothing to prove. For $n = 0$ we have $f = z$ for some $z \in \mathbb{C}$. Then $f\overline{f} = z\overline{z} \in \mathbb{R}$, by the above. For the induction step we write $f = f[n]\,t^n + r(t)$, where $r \in \mathbb{C}[t]$ is of degree $\deg(r) \leq n-1$. Then $\overline{f} = \overline{f[n]}\,t^n + \overline{r}$ and thereby

$$f\overline{f} \;=\; \big(f[n]\,t^n + r(t)\big)\left(\overline{f[n]}\,t^n + \overline{r}(t)\right) \;=\; f[n]\overline{f[n]}\,t^{2n} + \Big(f[n]\,\overline{r}(t) + \overline{f[n]}\,r(t)\Big)\,t^n + r\overline{r}$$

Hereby $f[n]\overline{f[n]} \in \mathbb{R}$ is clear again, by the above. And $r\overline{r} \in \mathbb{R}[t]$ is true, by induction hypothesis. It remains to prove, that the middle term is a polynomial over the reals, as well. So let us take a closer look:

$$\begin{aligned} f[n]\,\overline{r}(t) + \overline{f[n]}\,r(t) \;&=\; \sum_{k=0}^{n-1} \Big(f[n]\,\overline{f[k]} + \overline{f[n]}\,f[k]\Big)\,t^k \\ &=\; \sum_{k=0}^{n-1} \Big(f[n]\,\overline{f[k]} + \overline{f[n]\,\overline{f[k]}}\Big)\,t^k \end{aligned}$$

So if we let $s[k] := f[n]\,\overline{f[k]} \in \mathbb{C}$ then the coefficients of this polynomial are given to be $s[k]+\overline{s[k]} \in$

$\mathbb{R}$ and thereby the middle term is a polynomial in $\mathbb{R}[t]$, as well. And from this we finally get $f\overline{f} \in \mathbb{R}[t]$.

(ii) The proof is analytic in nature and hence we only try to get the idea across and not fill in every technical detail. We use standard arguments of a course in analysis of one real variable (■) : Let $n := \deg(p) = 2m+1$, then the leading coefficient $p[n] \neq 0$ is non-zero. Without loss of generality we may assume $p[n] > 0$: If not we could find a root x of $-p$, which also is a root of p. We consider $p \in \mathbb{R}(t)$ and use this to divide p by t^n. We also pull out $p[n]$, that is we rewrite p in the form

$$\frac{p(t)}{t^n} \;=\; \frac{1}{t^n}\sum_{k=0}^{n} p[k]\,t^k \;=\; p[n]\left(1+\sum_{k=0}^{n-1}\frac{p[k]}{p[n]}\,\frac{1}{t^{n-k}}\right)$$

In the limit $x \to \pm\infty$ the terms $1/x^{n-k} \to 0$ vanish so $p(x)/x^n$ converges to $p[n]$. And as $p(x)/x^n$ converges to $p[n]$, $p(x)$ has to stick to $p[n]\,x^n$ as x tends to $\pm\infty$. But as $n \geq 1$ and n is odd, we have $x^n \to \pm\infty$ for $x \to \pm\infty$. Altogether we conclude

$$\lim_{x\to\pm\infty} p(x) \;=\; \lim_{x\to\pm\infty} p[n]\,x^n \;=\; \pm\infty$$

That is there is some $r > 0$ such that $p(-r) < 0 < p(r)$. As p is continuous there has to be some $x \in \mathbb{R}$ with $-r < x < r$ such that $p(x) = 0$ and this is just what we sought for.

(iii) Let us first regard the case of a monic polynomial $p \in \mathbb{R}[t]$ over the reals, such that $n := \deg(p) \geq 1$. We claim, that $p(z) = 0$ for some $z \in \mathbb{C}$. Write $n = 2^k m$ for some $k \in \mathbb{N}$ and $1 \leq m \in \mathbb{N}$ such that m is odd. We prove the claim by induction on k: If $k = 0$, then $n = m \geq 1$ is odd and thereby even $p(x) = 0$ for some $x \in \mathbb{R}$, due to (ii). Now for the induction step:

By (8.10.(iv)) there is some field K such that $K : \mathbb{C}$ is a finite field extension and p splits over K. That is there are $z_1, \ldots, z_n \in K$, such that p can be written, as

$$p \;=\; (t-z_1)\ldots(t-z_n) \;=\; t^n - a_1 t^{n-1} + \cdots + a_{n-1}t + a_n$$

As $p \in \mathbb{R}[t]$ we have $a_i \in \mathbb{R}$ and we could even express the a_i in terms of elementary symmetric polynomials in the z_i. Whatever, let $R := \mathbb{R}[t]$ and fix any $a \in \mathbb{R}$. Then we define another monic polynomial $s_a \in R[t_1, \ldots, t_n]$, this time

$$s_a(t_1, \ldots, t_n) \;=\; \prod_{1\leq i<j\leq n} \big(t - (t_i + t_j) - a t_i t_j\big)$$

Obviously s_a is symmetric and hence by (7.67.(iv)) there is some polynomial $h \in R[t_1, \ldots, t_n]$ such that s_a satisfies the identity

$$s_a(z_1, \ldots, z_n) \;=\; h(a_1, \ldots, a_n) \;=:\; g_a(t) \;\in\; \mathbb{R}[t]$$

That is $g_a \in \mathbb{R}[t]$ and $s_a(z_1, \ldots, z_n) \in K[t]$ have the same degree and share the same coefficients. So let us take a look at the degree of $s_a(z_1, \ldots, z_n)$. By construction we have

$$\deg\big(s_a(z_1, \ldots, z_n)\big) \;=\; \sum_{1\leq i<j\leq n} 1 \;=\; \frac{n(n-1)}{2} \;=\; \frac{2^k m(n-1)}{2} \;=\; 2^{k-1}m(n-1)$$

As $k \geq 1$ we find n to be even, such that $n-1$ is odd. This makes $m(n-1)$ odd, too. Therefore we can use the induction hypothesis on g_a which means that there is some $z_a \in \mathbb{C}$ such that $g_a(z_a) = 0$. Take a look at the expression behind

$$0 \;=\; g_a(z_a) \;=\; s_a(z_1,\ldots,z_n)(z_a) \;=\; \prod_{1\leq i<j\leq n} \big(z_a - (z_i+z_j) - az_iz_j\big)$$

As K is a field and hence an integral domain this means that one of the factors has to be zero. Time to summarize what we have got so far: For any $a \in \mathbb{R}$ there is some $z_a \in \mathbb{C}$ such that for some $i, j \in 1\ldots n$ with $i < j$ we get the equation

$$z_a - (z_i + z_j) - az_iz_j \;=\; 0$$

As $\mathbb{R}^*$ is infinite and there only are finitely many (i,j) with $1 \leq i < j \leq n$ there have to be two distinct $a \neq b \in \mathbb{R}^*$ that belong to the same pair (i,j). That is

$$\begin{aligned} z_a &= z_i + z_j + az_iz_j \\ z_b &= z_i + z_j + bz_iz_j \end{aligned}$$

Subtracting these equations, we get $z_b - z_a = (b-a)z_iz_j$ and as $b - a \neq 0$ this can be turned into $z_iz_j = (a_b - z_a)(b-a)^{-1} \in \mathbb{C}$. And multiplying the first equation by b, the second with a and subtracting we also find $bz_a - az_b = (b-a)(z_i+z_j)$ which turns into $z_i + z_j = (bz_a - az_b)(b-a)^{-1} \in \mathbb{C}$. Altogether we have both $z_i + z_j$ and $z_iz_j \in \mathbb{C}$ and thereby

$$(t-z_i)(t-z_j) \;=\; t^2 - (z_i+z_j)t + z_iz_j \;\in\; \mathbb{C}[t]$$

That is z_i and z_j are the roots of a quadratic polynomial polynomial of $\mathbb{C}[t]$. But by (7.77) the roots of such a polynomial are uniquely determined elements of $\mathbb{C}$. That is z_i and $z_j \in \mathbb{C}$ themselves and in particular $p(z_i) = 0$ for some $z_i \in \mathbb{C}$.

It remains to prove the general case $f \in \mathbb{C}[t]$ where $n = \deg(f) \geq 1$. In this case $p := f\overline{f} \in \mathbb{R}[t]$ is a polynomial over the reals of degree $2n \geq 1$. By what we have argued above, there is some $z \in \mathbb{C}$ such that $p(z) = 0$ and by construction that is $f(z)\overline{f}(z) = 0$. As $\mathbb{C}$ is a field we conclude $f(z) = 0$ (which is what we wanted) or $\overline{f}(z) = 0$. In the latter case (i) tells us $\overline{f(\overline{z})} = 0$ such that $f(\overline{z}) = 0$. That is $\overline{z} \in \mathbb{C}$ is a root of f, which is good enough for the claim to be true.

□

Proof of (3.89):
Let us start with (a) $\implies$ (b): By assumption we have $\alpha : M \to L$ such that $\alpha\varphi = \mathbb{1}_L$. Let us consider any $x \in M$. Then $\alpha(x - \varphi\alpha(x)) = \alpha(x) - \alpha\varphi\alpha(x) = \alpha(x) - \alpha(x) = 0$. That is $x - \varphi\alpha(x) \in \ker(\alpha)$ and as $\varphi\alpha(x) \in \operatorname{im}(\varphi)$ also $x \in \ker(\alpha) + \operatorname{im}(\varphi)$. As $x \in M$ has been arbitrary this means $M = \ker(\alpha) + \operatorname{im}(\varphi)$. Now suppose we had $x \in \ker(\alpha) \cap \operatorname{im}(\varphi)$, say $x = \varphi(u)$, then $0 = \alpha(x) = \alpha\varphi(u) = u$ such that $x = \varphi(u) = \varphi(0) = 0$. That is $\ker(\alpha) \cap \operatorname{im}(\varphi) = 0$. So together we have proved

$$M \;=\; \ker(\alpha) \oplus \operatorname{im}(\varphi)$$

We are on the way to construct $\omega : N \to M$, so now consider $x, y \in M$ with $\psi(x) = \psi(y)$. Then we have $0 = \psi(x) - \psi(y) = \psi(x - y)$ such that $x - y \in \ker(\psi) = \operatorname{im}(\varphi)$. But of course $\varphi\alpha(y - x) \in \operatorname{im}(\varphi)$, too such that

$$(x - y) + \varphi\alpha(y - x) \ \in \ \operatorname{im}(\varphi)$$

Yet $(x - y) + \varphi\alpha(y - x) = x - y + \varphi\alpha(y) - \varphi\alpha(x) = (x - \varphi\alpha(x)) - (y - \varphi\alpha(y))$ and as we have seen above $x - \varphi\alpha(x)$ and $y - \varphi\alpha(y) \in \ker(\alpha)$. Therefore we also find that

$$(x - y) + \varphi\alpha(y - x) \ = \ (x - \varphi\alpha(x)) - (y - \varphi\alpha(y)) \ \in \ \ker(\alpha)$$

Together this is $(x - \varphi\alpha(x)) - (y - \varphi\alpha(y)) \in \operatorname{im}(\varphi) \cap \ker(\alpha) = 0$ such that $\psi(x) = \psi(y)$ implies $x - \varphi\alpha(x) = y - \varphi\alpha(y)$. Note however, that ψ is surjective by assumption, so for any $p \in N$ there is some $x \in M$ such that $p = \psi(x)$. And thereby we may finally define

$$\omega(p) \ := \ x - \varphi\alpha(x) \ \text{ for some } x \in M \text{ with } \psi(x) = p$$

This is well defined, as the result of $\omega(p)$ does not depend on the actual choice of x, as we have just argued. And as both ψ and $\mathbb{1}_M - \varphi\alpha$ are homomorphisms, so is ω. Now it is easy to compute $\psi\omega(p) = \psi(x - \varphi\alpha(x)) = \psi(x) - \psi\varphi\alpha(x) = \psi(x) - 0\alpha(x) = \psi(x) = p$ such that $\psi\omega = \mathbb{1}_N$. Thus we have arrived at (b).

The proof of (b) $\implies$ (a) is rather analogous: We have $\omega : N \to M$ such that $\psi\omega = \mathbb{1}_N$ and need to construct $\alpha : M \to L$. Given $x \in M$ we see $\psi(x - \omega\psi(x)) = \psi(x) - \psi\omega\psi(x) = \psi(x) - \psi(x) = 0$ such that $x - \omega\psi(x) \in \ker(\psi)$. And as $\omega\psi(x) \in \operatorname{im}(\omega)$ this is $x \in \ker(\psi) + \operatorname{im}(\omega)$. As x has been arbitrary we have found $M = \ker(\psi) + \operatorname{im}(\omega)$ again. Now suppose $x \in \ker(\psi) \cap \operatorname{im}(\omega)$, say $x = \omega(p)$ for some $p \in N$. Then $0 = \psi(x) = \psi\omega(p) = p$ such that $x = \omega(p) = \omega(0) = 0$. That is we also have $\ker(\psi) \cap \operatorname{im}(\omega) = 0$ again and thereby

$$M \ = \ \ker(\psi) \oplus \operatorname{im}(\omega)$$

We are on the way to construct $\alpha : M \to L$, as we have seen for any $x \in M$ we have $x - \omega\psi(x) \in \ker(\psi) = \operatorname{im}(\varphi)$. And as φ is injective by assumption there is a uniquely determined $u \in L$ such that $\varphi(u) = x - \omega\psi(x)$. Thus we may define

$$\alpha(x) \ := \ u \ \text{ where } u \in L \text{ with } \varphi(u) = x - \omega\psi(x)$$

As both φ and $\mathbb{1}_M - \omega\psi$ are homomorphisms, so is α. It remains to verify $\alpha\varphi = \mathbb{1}_L$. Thus consider any $u \in L$ and let $x := \varphi(u)$. Then $x - \omega\psi(x) = \varphi(u) - \omega\psi\varphi(u) = \varphi(u) - \omega 0(u) = \varphi(u)$. That is we have $\alpha(x) = u$ by definition of α, but this again is $\alpha\varphi(u) = u$ as needed. Thus we have arrived at (a), together we have (a) $\iff$ (b).

Now that the equivalence of (a) and (b) has been established, we will prove that $\ker(\alpha) = \operatorname{im}(\alpha)$ is in fact the same sub-module: We have seen that M can be decomposed into the inner direct sums

$$\begin{aligned} M &= \ker(\alpha) \oplus \operatorname{im}(\varphi) \\ M &= \operatorname{im}(\omega) \oplus \ker(\psi) \end{aligned}$$

But thereby $L' := \mathrm{im}(\varphi) = \mathrm{kn}(\psi)$ is precisely the same set. Thus the inner direct sums gives rise to the following isomorphisms

$$\begin{array}{rcl} \mathrm{kn}(\alpha) & \xrightarrow{\sim} & M \Big/ L' \ : \ k \mapsto k + L' \\ \mathrm{im}(\omega) & \xrightarrow{\sim} & M \Big/ L' \ : \ j \mapsto j + L' \end{array}$$

Composing these isomorphisms $k \mapsto k + L' \mapsto k$ we find that the identity map is an isomorphism from $\mathrm{kn}(\alpha)$ to $\mathrm{im}(\omega)$. But the identity maps $\mathrm{kn}(\alpha)$ to itself so we have $\mathrm{im}(\omega) = \mathrm{kn}(\alpha)$.

The implication (c) $\implies$ (a) and (b) is rather easy: Let us denote the canonical homomorphisms $\pi_L : L \oplus N \to L$ given by $\pi_L(u,p) := u$ and $\iota_L : L \to L \oplus N$ given by $\iota_L(u) := (u,0)$. Likewise $\pi_N : L \oplus N \to N$ and $\iota_N : N \to L \oplus N$. If we have the isomorphism $\Phi : M \xrightarrow{\sim} L \oplus N$ then we may explicitly define $\alpha : M \to L$ and $\omega : N \to M$ to be

$$\begin{array}{rcl} \alpha & := & \pi_L \Phi \\ \omega & := & \Phi^{-1} \iota_N \end{array}$$

Recall that we have the commutativity of the diagram, that is $\Phi\varphi = \iota_L$ and $\pi_N \Phi = \psi$. Then for any $u \in L$ it is clear that $\alpha\varphi(u) = \pi_L \Phi \varphi(u) = \pi_L \iota_L(u) = u$. And likewise $\pi_N \Phi = \psi$ turns into $\pi_N = \psi \Phi^{-1}$ such that for any $p \in N$ we have $\psi\omega(p) = \psi\Phi^{-1}\iota_N(p) = \pi_N \iota_N(p) = p$. Thus α and ω satisfy the required properties and we have (a) and (b).

It remains to verify (a) and (b) $\implies$ (c): Again this can be done explicitly, given α let us define

$$\Phi \ : \ M \to L \oplus N \ : \ x \mapsto \big(\alpha(x), \psi(x)\big)$$

Clearly Φ is a homomorphism and we also find the commutativity of the diagram: For any $u \in L$ we get $\Phi\varphi(u) = (\alpha\varphi(u), \psi\varphi(u)) = (u,0) = \iota_L(u)$. And for any $x \in M$ we have $\pi_N \Phi(x) = \pi_N(\alpha(x), \psi(x)) = \psi(x)$. The inverse of Φ is given to be

$$\Phi^{-1} \ : \ L \oplus N \to M \ : \ (u,p) \mapsto \varphi(u) + \omega(p)$$

Let us verify, that this truly is the inverse: Starting with $x \in M$ we decompose $x = k + \ell$ for some $k \in \mathrm{kn}(\alpha) = \mathrm{im}(\omega)$ and $\ell \in \mathrm{im}(\varphi) = \mathrm{kn}(\psi)$. That is we may choose $u \in L$ and $p \in N$ such that $k = \omega(p)$ and $\ell = \varphi(u)$. Then

$$\begin{array}{rcl} \Phi^{-1}\Phi(x) & = & \varphi\alpha(x) + \omega\psi(x) \\ & = & \varphi\alpha(k+\ell) + \omega\psi(k+\ell) \\ & = & \varphi\alpha(\ell) + \omega\psi(k) \\ & = & \varphi\alpha\varphi(u) + \omega\psi\omega(p) \\ & = & \varphi(u) + \omega(p) \ = \ \ell + k \ = \ x \end{array}$$

Conversely for $u \in L$ and $p \in N$ then the composition of Φ after Φ^{-1} yields

$$\Phi\Phi^{-1}(u,p) \ = \ \big(\alpha\big(\varphi(u) + \omega(p)\big), \psi\big(\varphi(u) + \omega(p)\big)\big)$$

As $\omega(p) \in \mathrm{im}(\omega) = \mathrm{kn}(\alpha)$ and $\varphi(u) \in \mathrm{im}(\varphi) = \mathrm{kn}(\psi)$ we can drop $\omega(p)$ in α and likewise $\varphi(u)$ in ψ. It only remains the identity desired

$$\Phi\Phi^{-1}(u,p) \;=\; \big(\alpha\varphi(u), \psi\omega(p)\big) \;=\; (u,p)$$

□

Proof of (3.90):
Since N is free we may choose a basis $\{\, n_i \mid i \in I \,\}$ of N. And as ψ is surjective, we may choose some $m_i \in M$ such that $\psi(m_i) = n_i$ for any $i \in I$. Then we may define

$$\omega \;:\; N \to M \;:\; \sum_{i\in I} a_i n_i \mapsto \sum_{i\in I} a_i m_i$$

This is a well-defined homorphism, that satisfies $\psi\omega(n_i) = \psi(m_i) = n_i$ for any $i \in I$. As the n_i generate N this is $\psi\omega(x) = x$ and hence $\psi\omega = \mathbb{1}_N$. Thus we have property (b) in (3.89) such that by property (c) there is some isomorphism $\Phi : M \xrightarrow{\sim} L \oplus N$ that makes the diagram commute. □

Proof of (4.23):

(i) Clearly, if $b \notin \mathrm{im}(A)$, then $Ax = b$ has no solution at all, hence $\mathbb{L}(Ax = b) = \emptyset$. Conversely if $b \in \mathrm{im}(A)$ then we can pick up some $u \in R^n$ with $Au = b$. Now if $v \in \mathrm{kn}(A)$ then $A(u+v) = Au + Av = b + 0 = b$. And as v has been arbitrary, this means $u + \mathrm{kn}(A) \subseteq \mathbb{L}(Ax = b)$. Conversely consider some x with $Ax = b$, then $A(x-u) = Ax - Au = b - b = 0$ and hence $v := x - u \in \mathrm{kn}(A)$. Again, as x has been arbitrary that is $\mathbb{L}(Ax = b) \subseteq u + \mathrm{kn}(A)$.

(ii) First of all let us compute $DT^{-1} = SATT^{-1} = SA$. Further note that - due to the invertibility of S - we have the equivalence

$$b \;=\; Ax \quad\Longleftrightarrow\quad Sb \;=\; SAx \;=\; DT^{-1}x$$

Now for (a) $\Longrightarrow$ (b): let us define $z := T^{-1}x$, then $Dz = DT^{-1}x = SAx = Sb$. And $x = TT^{-1}x = Tz$ is clear, as well. Conversely for (b) $\Longrightarrow$ (a): if $x = Tz$ then $z = T^{-1}Tz = T^{-1}x$ and hence also $Sb = Dz = DT^{-1}x$ and hence $b = Ax$ by the equivalence above.

(iii) By definition $x \in \mathbb{L}(Ax = b)$ means that $Ax = b$. As we have seen in (ii) this is equivalent to $x = Tz$ and $Dz = Sb$ for some $z \in R^n$. Again this translates into $x = Tz$ and $z \in \mathbb{L}(Dx = Sb)$. And this is nothing but $x \in T\,\mathbb{L}(Dx = Sb)$.

(iv) Due to (i) we know that $\mathbb{L}(Dx = Sb)$ either is empty (if $Sb \notin \mathrm{im}(D)$) or given to be $u + \mathrm{kn}(D)$ for some special solution $Du = Sb$. Now by (iii) we have $\mathbb{L}(Ax = b) = R\mathbb{L}(Dx = Sb) = R(u + \mathrm{kn}(D))$. And since a matrix always defines an R-linear operation, this yields $\mathbb{L}(Ax = b) = Ru + R\,\mathrm{kn}(D)$.

□

Proof of (4.24):

- Since $\mathrm{im}(L) = a_1R + \cdots + a_nR = dR$ according to (2.83.(iii)) we have $b \in \mathrm{im}(L) = dR$ if and only if $d \mid b$. So $\mathbb{L} \neq \emptyset$ clearly is equivalent to $b \in \mathrm{im}(L)$ which in turn is equivalent to $d \mid b$. In

particular we may pick up some $u = (u_1, \ldots, u_n) \in R^n$ such that $L(u) = d \in dR = \mathrm{im}(L)$. That is $a_1u_1 + \cdots + a_nu_n = d$. In case $d \mid b$ there is some $\beta = b/d \in R$ satisfying $d\beta = b$, so multiplying this equation with this β yields (due to the R-linearity of L)

$$L(\beta u) \;=\; \beta L(u) \;=\; \beta d \;=\; d$$

such that $s = \beta u$ truly is a special solution to the equation $L(x) = b$. It is immediately to see that $s = (\beta u_1, \ldots, \beta u_n) \in \mathbb{L}$ is the special solution given in the claim above.

- In case $n = 1$ there is next to nothing to prove: clearly $x_1 = \beta u_1 = \beta = b/d = b/a_1$ is the special solution and this is uniquely determined since R has been assumed to bee an integral domain (even an Euclidean domain).

- In case $n = 2$ we have to prove the equality of the kernel $K := \mathrm{kn}(L)$, once this is established we know $\mathbb{L} = s + K$ from (4.23). So let us denote $\alpha_i = a_i/d$ (that is $d\alpha_i = a_i$) and consider some $x \in R^2$ of the form $x = (\alpha_2, -\alpha_1)t$ for some $t \in R$. Then it is clear that $L(x) = a_1x_1 + a_2x_2 = a_1\alpha_2 t - a_2\alpha_1 t = d\alpha_1\alpha_2 t - d\alpha_2\alpha_1 t = dt(\alpha_1\alpha_2 - \alpha_2\alpha_1) = 0$ such that $(\alpha_2, -\alpha_1)R \subseteq K$. Conversely given $x \in K$, that is $L(x) = a_1x_1 + a_2x_2 = 0$, then already $d(\alpha_1x_1 + \alpha_2x_2) = 0$. And since a_1 and $a_2 \neq 0$ we have $d = 0$ such that necessarily $\alpha_1x_1 = -\alpha_2x_2$. In particular we have $\alpha_1 \mid \alpha_2x_2$. But according to (2.58.(v)) we also know that $1 \in \gcd\{\alpha_1, \alpha_2\}$ such that by (2.64.(iv)) we get $\alpha_1 \mid x_2$, that is $x_2 = \alpha_1 t_1$ for some $t_1 \in R$. Likewise we find $x_1 = \alpha_2 t_2$ for some $t_2 \in R$. Using these equations we find $0 = \alpha_1x_1 + \alpha_2x_2 = \alpha_1\alpha_2t_2 + \alpha_2\alpha_1t_1 = \alpha_1\alpha_2(t_1 + t_2)$. Since both $\alpha_i \neq 0$ are non-zero we get $t_2 = -t_1$ such that (abbreviating $t := t_1$) we have $x_1 = \alpha_2 t$ and $x_2 = -\alpha_1 t$. This also proves the inclusion $(\alpha_2, -\alpha_1)R \subseteq K$.

- We will prove this statement by induction on the number $n \geq 2$ of variables. The case $n = 2$ has already been shown above (note that $d_1 = \gcd\{a_1\} = a_1$ and $d_2 = \gcd\{a_1, a_2\} = d$) so we continue with the induction step where $n \geq 3$. That is we regard the equation

$$a_1x_1 + \cdots + a_nx_x + a_{n+1}x_{n+1} \;=\; b$$

This equation admits a solution if and only if the greatest common divisor d_{n+1} divides b, that is iff $d_{n+1} = \gcd\{a_1, \ldots, a_n, a_{n+1}\} \mid b$. If this is untrue, then there is nothing to prove, since there is no special solution $s = b/d_{n+1}(u_{1,n+1}, \ldots, u_{n,n+1}, u_{n,n+1})$. But clearly this equation is equivalent to $a_1x_1 + \cdots + a_nx_x = b - a_{n+1}x_{n+1}$ and we know that this equation is solvable if and only if $d_n = \gcd\{a_1, \ldots, a_n\} \mid b - a_{n+1}x_{n+1}$ (note that this is equivalent to the solubility of the original equation as well). That is, there is some $z \in R$ such that we have the system of equations

$$\begin{aligned} b - a_{n+1}x_{n+1} &= zd_n \\ a_1x_1 + \cdots + a_nx_n &= zd_n \end{aligned}$$

Let us abbreviate $y = x_{n+1}$ and note that the first of these equations can be reformulated, as $a_{n+1}y + d_nz = b$. From the case $n = 2$ we already know that the solutions to this equation are given to be

$$(y, z) \;=\; \left(\frac{b}{d_{n+1}}v,\; \frac{b}{d_{n+1}}w\right) + \left(\frac{d_n}{d_{n+1}},\; -\frac{a_{n+1}}{d_{n+1}}\right) r$$

Where $r \in R$ is an arbitrary coefficient, that spans a 1-dimensional space of solutions. This is due to (2.64.(vii)) where we have seen, that $\gcd\{d_n, a_{n+1}\} = \gcd\{\gcd\{a_1, \ldots, a_n\}, a_{n+1}\} = \gcd\{a_1, \ldots, a_{n+1}\} = d_{n+1}$ and finally $v, w \in R$ are some elements satisfying $a_{n+1}v + d_n w = d_{n+1}$. Note that this can be achieved, by letting $v := u_{n+1,n+1}$ and

$$w \;:=\; \frac{a_1}{d_n}u_{1,n+1} + \cdots + \frac{a_n}{d_n}u_{n,n+1}$$

as in this case we get $a_{n+1}v + d_n w = a_{n+1}u_{n+1,n+1} + a_1 u_{1,n+1} + \cdots + a_n u_{n,n+1} = d_{n+1}$ by construction of the $u_{i,k}$. Let us finally take the coefficient to be $r_n := -r \in R$ instead, then we have

$$\begin{aligned} x_{n+1} &= \frac{b}{d_{n+1}}u_{n+1,n+1} - \frac{d_n}{d_{n+1}}r_n \\ z &= \frac{b}{d_{n+1}}w + \frac{a_{n+1}}{d_{n+1}}r_n \end{aligned}$$

We now apply the induction hypothesis to the second equation in our system $a_1x_1 + \cdots + a_n x_n = zd_n$ yielding the solutions $x \in s + \mathrm{im}(A)$ where $s \in R^n$ is a special solution, such as

$$\begin{aligned} s &= \left(\frac{zd_n}{d_n}u_{1,n}, \ldots, \frac{zd_n}{d_n}u_{n,n}\right) \\ &= (zu_{1,n}, \ldots, zu_{n,n}) \;=\; z(u_{1,n}, \ldots, u_{n,n}) \\ &= \left(\frac{b}{d_{n+1}}w + \frac{a_{n+1}}{d_{n+1}}r_n\right)(u_{1,n}, \ldots, u_{n,n}) \end{aligned}$$

So let us regard the solution $x = s + Ar$ where $x = (x_1, \ldots, x_n)$ and $r = (r_1, \ldots, r_{n-1})$, then we find that x_k ($k \in 1 \ldots n$) is given to be

$$x_k \;=\; s_k + [Ar]_k \;=\; \frac{b}{d_{n+1}}u_{k,n}w + \frac{a_{n+1}}{d_{n+1}}u_{k,n}r_n + [Ar]_k$$

Combining this result for the previous x_k ($k \in 1 \ldots n$) with our result for the current step x_{n+1} we arrive at the following matrix representation of the solution of the original equation $(x_1, \ldots, x_n, x_{n+1}) =$

$$\begin{pmatrix} bu_{1,n}w/d_{n+1} \\ \vdots \\ bu_{n,n}w/d_{n+1} \\ bu_{n+1,n+1}/d_{n+1} \end{pmatrix} + \begin{pmatrix} \boxed{A} & \begin{matrix} a_{n+1}u_{1,n}/d_{n+1} \\ \vdots \\ a_{n+1}u_{u,n}/d_{n+1} \end{matrix} \\ 0 \;\cdots\; 0 & -d_n/d_{n+1} \end{pmatrix} \begin{pmatrix} r_1 \\ \vdots \\ r_{n-1} \\ r_n \end{pmatrix}$$

It is plain to see, that this matrix is precisely the matrix given in the claim in the case of $n+1$ variables. In order to distinguish the $n \times (n-1)$ matrix A from this $(n+1) \times n$-matix, let us denote the latter by A'. Let us also denote this special solution by $s' := (bu_{1,n}w/d_{n+1}, \ldots, bu_{n,n}w/d_{n+1}, bu_{n+1,n+1}/d_{n+1})$. Then we only have to argue, that we can shift this solution s' in such a way, that we truly get $x = s + A't$ for some $t \in R^n$ and the special solution $s = b/d_{n+1}(u_{1,n+1}, \ldots, u_{n+1,n+1}) \in R^{n+1}$ given in the claim. To do this recall that

$$d_n w \;=\; (a_1u_{1,n} + \cdots + a_n u_{n,n})w \;=\; a_1u_{1,n}w + \cdots + a_n u_{n,n}w$$

Inserting this into $d_{n+1} = d_n w + a_{n+1}u_{n+1,n+1}$ we find two distinct equations for the greates common divisor d_{n+1} namely

$$\begin{aligned} d_{n+1} &= a_1u_{1,n}w + \cdots + a_nu_{n,n}w + a_{n+1}u_{n+1,n+1} \\ d_{n+1} &= a_1u_{1,n+1} + \cdots + a_nu_{n,n+1} + a_{n+1}u_{n+1,n+1} \end{aligned}$$

Subtracting these two equations we see, that $0 = a_1(u_{1,n}w - u_{1,n+1}) + \cdots + a_n(u_{n,n}w - u_{n,n+1})$. Let us now take $k = (k_1, \ldots, k_n)$ to be

$$k_j := \frac{b}{d_{n+1}}(u_{j,n}w - u_{j,n+1})$$

then by construction we see that $s' = s + (k_1, \ldots, k_n, 0)$ is the special solution we found above. But it also is clear that $a_1k_1 + \cdots + a_nk_n = 0$. That is k is a solution to the homogeneous equation $L(k) = 0$ and by induction hypothesis this means $k \in \mathrm{im}(A)$. That is $k = Aq$ for some $q \in R^{n-1}$. Let us now define $t = (t_1, \ldots, t_n) := (r_1, \ldots, r_n) + (q_1, \ldots, q_{n-1}, 0)$ then we clearly have $A't = A'r + (Aq, 0) = A'r + (k, 0)$ such that $s + A't = s + (k, 0) + A'r = s' + A'r = x$. That is we can also parametrisize the solutions x in the form $x = s + A't$ by taking to the shift $t = r + (k, 0)$ which is a bijection.

□

Proof of (4.29):

We will prove the following claim by induction on the number m of rows of the matrix A: using the Gaussian algorithm one obtains an $(m \times m)$-matrix S and an $(m \times n)$-matrix E such that E is in echelon-form. The fact, that S is a product of elementary matrices is clear from the algorithm - no other matrices are involved.

In the case $A = 0$ the algorithm already terminates at step (2), so we are left with $S = \mathbb{1}_m$ and $E = A = 0$. In this case $E = 0$ trivially is in echelon-form and $E = SA$ is clear.

So let us now assume $A \neq 0$. We first anchor the induction for $m = 1$. As $A \neq 0$ we necessarily have $s = 1 = r$ and the pivot step is skipped. Likewise the main step (5) is void, as $r + 1 \ldots m$ is empty. So again $E = A$ is in echelon-form and $E = SA$. And as $m = r$ the algorithm terminates.

Let us now assume that the claim has been proved for any matrix B with less than m rows. Then we need to show, that the claim holds true for A as well. The algorithm starts with row $r = 1$. And as $A \neq 0$ the algorithm does not terminate in (2) but targets u and s such that $u = \mu(A)$ and $\mu(\mathrm{row}_s A) = u$. In case $s \neq r = 1$ the rows 1 and s are interchanged $E = P_{r,s}A = SA$. So after step (4) we can be sure, that $\mu(\mathrm{row}_1 E) = \mu(E)$ is minimal. That is the first $u - 1$ columns of E are zero. Let us denote $p = m - 1$ and $q := n - u$ then E is of the form

$$E = \begin{pmatrix} 0 & \cdots & 0 & x_0 & x_1 & \cdots & x_q \\ 0 & \cdots & 0 & y_1 & h_{1,1} & \cdots & h_{1,q} \\ \vdots & & \vdots & \vdots & \vdots & & \vdots \\ 0 & \cdots & 0 & y_p & h_{p,1} & \cdots & h_{p,q} \end{pmatrix}$$

That is $x = (x_0, x_1, \ldots, x_q)$ where $x_j = e_{1,u+j}$ and $y = (y_1, \ldots, y_p)$ where $y_i = e_{i+1,u}$ and $H = (h_{i,j})$ where $h_{i,j} = e_{i+1,u+j}$. Now the main step (5) is initiated. For any $i \in 2 \ldots m$ the following row-operations

are performed

$$\mathrm{row}_i E \;:=\; e_{r,u}(\mathrm{row}_i E) - e_{i,u}(\mathrm{row}_r E)$$

Specifically for the u-th column of E (that is the u-th entry of $\mathrm{row}_i E$) this is $[\mathrm{row}_i E]_u = e_{r,u}e_{i,u} - e_{i,u}e_{r,u}$ and as R is commutative this means $[\mathrm{row}_i E]_u = 0$. Hence *after* the main step the matrix E is turned into

$$E \;=\; \begin{pmatrix} 0 & \cdots & 0 & x_0 & x_1 & \cdots & x_q \\ 0 & \cdots & 0 & 0 & b_{1,1} & \cdots & b_{1,q} \\ \vdots & & \vdots & \vdots & \vdots & & \vdots \\ 0 & \cdots & 0 & 0 & b_{p,1} & \cdots & b_{p,q} \end{pmatrix}$$

For some matrix $B = (b_{i,j})$ where $i \in 1 \ldots p = m-1$ and $j \in 1 \ldots q$. Now the Gaussian algorithm iterates with $r = 2$. As B has $m-1$ rows only, the induction hypothesis yields that the Gaussian algorithm will also transform B into echelon form. So after the algorithm terminates B is in echelon form i.e. there is some $r \in 1 \ldots m-1$ such that $\mu(\mathrm{row}_1 B) < \cdots < \mu(\mathrm{row}_r B)$ and for all $i > r$ we get $\mathrm{row}_i B = 0$. As E is in the form presented in the equation above, we have $\mu(\mathrm{row}_1 E) = u < u + \mu(\mathrm{row}_1 B) = \mu(\mathrm{row}_2 E)$ and hence

$$\mu(\mathrm{row}_1 E) \;<\; \ldots \;< \mu(\mathrm{row}_{r+1} E)$$

And for $i > r+1$ we have $\mu(\mathrm{row}_{i-1} B) = 0$ and therefore $\mu(\mathrm{row}_i E) = 0$ due to the shape of E. That is E is in echelon form, as claimed. The fact that $E = SA$ is clear, as all the operations (multiplications with elementary matrices from the left) on A are performed on S simultaneously. □

Proof of (4.33):
We have to prove that the algorithm presented in (4.34) truly comes up with some matrices P_k, L_k (where $k \in 1 \ldots n$ that satisfy the properties claimed in (4.33). To do this let us enumerate the matrix U that is used in the k-th step by U_k. Upon initialisation of the algorithm, this is $P_0 = \mathbb{1}_{n+1}$ and $U_0 = A$. In a first step we will prove that $[U_k]_{i,j} = 0$ for any $1 \leq j < k$ and any $j < i \leq n+1$ and that

$$U_k \;=\; L_k P_k U_{k-1}$$

for any $k \in 1 \ldots n$. Of course we use induction on k for that and the case $k = 0$ is void. That is we only have to regard $k \geq 1$ and work our way up. And as $U_0 = A$ the above equation already means

$$U_k \;=\; L_k P_k \ldots L_1 P_1 A$$

From this we find that U_k is invertible: A was assumed to be invertible, P_k is a permutation matrix and L_k satisfies $L_k^* \in \mathrm{tri}^1_{n+1}(F)$. Thus U_k inherits the invertibility from these matrices. First thing in the k-th step, $q(k)$ is selected, this is possible, unless $[U_{k-1}]_{i,k} = 0$ for all $i \in k \ldots n+1$. But in this case U_{k-1} had determinant 0: By Laplace expansion we see, that the determinant of U_{k-1} is

$$\det(U_{k-1}) \;=\; \left(\prod_{j=1}^{k-1} [U_{k-1}]_{j,j}\right) \cdot \det \begin{pmatrix} [U_{k-1}]_{k,k} & \cdots & [U_{k-1}]_{k,n+1} \\ \vdots & & \vdots \\ [U_{k-1}]_{n+1,k} & \cdots & [U_{k-1}]_{n+1,n+1} \end{pmatrix}$$

so the first column of this submatrix would vanish, leaving determinant 0. But we have seen that U_k has

to be invertible, a contradiction. So we find a suitable $q(k) \in k \dots n+1$. The multiplication $P_k U_k$ swaps the k and the $q(k)$-th row of U_k, which is precisely, what the algorithm does next. We also see that the algorithm assembles the matrix $L_k = \mathbb{1}_{k-1} \oplus L'_k$ where

$$L'_k \;=\; \begin{pmatrix} 1 & 0 & \dots & 0 \\ [L_k]_{k+1,k} & 1 & & \vdots \\ \vdots & & \ddots & 0 \\ [L_k]_{n+1,k} & 0 & \dots & 1 \end{pmatrix}$$

And by induction hypothesis we have $[U_k]_{i,j} = 0$ for any $1 \leq j < k$ and any $j < i \leq n+1$. That is the first $k-1$ columns U_k have a triangular matrix $T_k \in \mathrm{tri}_{k-1}(F)$ at the top, such that U_k is of the form

$$U_k \;=\; \begin{pmatrix} T_k & U''_k \\ 0 & U'_k \end{pmatrix}$$

And as $q(k) \geq k$ the transposition matrix P_k only interchanges two rows in the lower part of this matrix, but does not change its block structure. For ease of notation we therefore ignore P_k for the moment, as the algorithm continues with $P_k U_k$ in place of U_k. Take a look at

$$L_k U_k \;=\; \begin{pmatrix} \mathbb{1}_{k-1} & 0 \\ 0 & L'_k \end{pmatrix} \begin{pmatrix} T_k & U''_k \\ 0 & U'_k \end{pmatrix} \;=\; \begin{pmatrix} T_k & U''_k \\ 0 & L'_k U'_k \end{pmatrix}$$

As $\mathrm{row}_i(L_k) = e_k$ for any $i \leq k$ we find that $\mathrm{row}_i(L_k U_k) = \mathrm{row}_i(U_k)$. For $i > k$ the i-th row of L_k is $[L_k]_{i,k} e_k + e_i$ such that vector-matrix multiplication yields

$$\mathrm{row}_i(L_k U_k) \;=\; [L_k]_{i,k}\, \mathrm{row}_k(U_k) + \mathrm{row}_i(U_k)$$

That is the algorithm mimics the matrix-multiplication $L_k U_k$ here. In particular for the k-th column of $L_k U_k$ we find that our choice of $[L_k]_{i,k}$ results in $[L_k U_k]_{i,k} = 0$ for any $i > k$, as

$$[L_k]_{i,k}\, [U_k]_{k,k} + [U_k]_{i,k} \;=\; 0$$

In particular $U_{k+1} = L_k P_k U_k$ is of the same shape, as U_k before, but the upper triangular matrix $T_{k+1} \in \mathrm{tri}_k(F)$ now is of size $(k \times k)$. When we end at $k = n$ we see that $U_{n+1} = L_n P_n U_n$ is an upper triangular matrix itself. And therefore

$$U \;=\; U_{n+1} \;=\; L_n P_n U_n \;=\; \dots \;=\; L_n P_n \dots L_1 P_1 A \;\in\; \mathrm{tri}_{n+1}(F)$$

Next we want to prove that $\widehat{L}_k$ is of the same shape, as L_k. Let us call this shape *lower-k-columns-only* matrix for the moment being. This is to say L_k satifies the properties

(1) for any $i \in 1 \dots n+1$ we have $[L_k]_{i,i} = 1$

(2) for any $i < k$ we have $[L_k]_{i,k} = 0$

(3) for any $j \neq k$ and any $i \neq j$ we have $[L_k]_{i,j} = 0$

By construction L_k is a lower-k-column-only matrix and we want to prove that thereby for any $l > k$ the matrix $L'_k := P_l L_k P_l$ is lower-k-column-only matrix, too: By construction P_l is the permutation matrix of the transposition $\tau = (l\, q(l))$, where $k < l \leq q(l)$. In particular we have $\tau(j) = j$ for any $j \leq k$. Thereby P_l is self-inverse, such that $L'_k = P_l L_k P_l^{-1}$ and then (4.21.(v)) tells us that the (i,j)-th entry of L'_k is

$$[L'_k]_{i,j} \;=\; [L_k]_{\tau(i),\tau(j)}$$

So let us now check the three properties of a lower-k-column-only matrix: For any i we have $[L'_k]_{i,i} = [L_k]_{\tau(i),\tau(i)} = 1$ as needed. For any $i < k$ we have $\tau(i) = i < k = \tau(k)$ such that $[L'_k]_{i,k} = [L_k]_{i,k} = 0$ is granted, as well. If $j \neq k$ then $\tau(j) \neq \tau(k) = k$, also if $i \neq j$ then $\tau(i) \neq \tau(j)$ and as $\tau(j) \neq k$ we find $[L'_k]_{i,j} = [L_k]_{\tau(i),\tau(j)} = 0$ from property (3) of L_k. Altogether we have proved, that $P_l L_k P_l$ is a lower-k-column-only matrix again. By induction it is now clear, that

$$\widehat{L}_k \;:=\; P_n \dots P_{k+1} L_k P_{k+1} \dots P_n$$

is a lower-k-column-only matrix, too. Next note that due to $P_n^2 = \mathbb{1}_{n+1}$ down to $P_{k+1}^2 = \mathbb{1}_{n+1}$ we find that $\widehat{L}_k$ and L_k are turned into each other, by commuting with $P_n \dots P_{k+1}$

$$\widehat{L}_k P_n \dots P_{k+1} \;=\; P_n \dots P_{k+1} L_k P_{k+1} \dots P_n P_n \dots P_{k+1} \;=\; P_n \dots P_{k+1} L_k$$

Now we are good and ready to turn $\widehat{L}PA$ into U: Just replace any $\widehat{L}_k P_n \dots P_{k+1}$ by $P_n \dots P_{k+1} L_k$ beginning with $\widehat{L}_1$ and working our way to the left. If we note that $\widehat{L}_n = L_n$, we end up with

$$\begin{aligned}
\widehat{L}PA &= \widehat{L}_n \dots \widehat{L}_1 P_n \dots P_2 P_1 A \\
&= \widehat{L}_n \dots \widehat{L}_2 P_n \dots P_3 P_2 L_1 P_1 A \\
&= \widehat{L}_n \dots \widehat{L}_3 P_n \dots P_3 L_2 P_2 L_1 P_1 A \\
&= \dots \\
&= \widehat{L}_n P_n L_{n-1} \dots L_1 P_1 A \\
&= L_n P_n L_{n-1} \dots L_1 P_1 A \;=\; U
\end{aligned}$$

□

Proof of (4.54):
We start by proving (a) $\Longrightarrow$ (c): For ease of notation let us only consider the transposition $\tau = (1\,2) \in S_n$. The general transposition $\tau = (i\,j)$ only requires more effort in writing out the proof, but conveys the same idea only. By assumption on D we may expand the following term

$$\begin{aligned}
0 &= D(a_1 + a_2, a_1 + a_2, a_3, \dots, a_n) \\
&= D(a_1, a_1, a_3, \dots, a_n) + D(a_1, a_2, a_3, \dots, a_n) \\
&\quad + D(a_2, a_1, a_3, \dots, a_n) + D(a_2, a_2, a_3, \dots, a_n) \\
&= 0 + D(a_1, a_2, a_3, \dots, a_n) + D(a_2, a_1, a_3, \dots, a_n) + 0
\end{aligned}$$

and therefore $D(a_2, a_1, a_3, \dots, a_n) = -D(a_1, a_2, a_3, \dots, a_n)$ such that we have arrived at (c). And clearly this implies (b), as by (1.18.(iv)) any permutation $\sigma \in S_n$ can be decomposed into transpositions $\sigma =$

$\tau_1\tau_2\ldots\tau_s$, such that (by induction on s) it is clear that

$$\begin{aligned} D(a_{\sigma(1)}, a_{\sigma(2)}, \ldots, a_{\sigma(n)}) &= (-1)^s D(a_1, a_2, \ldots, a_n) \\ &= \operatorname{sgn}(\sigma) D(a_1, a_2, \ldots, a_n) \end{aligned}$$

Thus we have seen (c) $\implies$ (b) and the converse implication is trivial. It remains to verify (c) $\implies$ (a): For ease of notation we will regard the case $a_1 = a_2$ only. Again the general case only requires more notational effort but grants no additional insight. So let us pick up the transposition $\tau = (1\,2)$, then by assumption we have $(a_{\tau(1)}, a_{\tau(2)}, \ldots, a_{\tau(n)}) = (a_1, a_2, \ldots, a_n)$, hence

$$\begin{aligned} D(a_1, a_2, \ldots, a_n) &= D(a_{\tau(1)}, a_{\tau(2)}, \ldots, a_{\tau(n)}) \\ &= -D(a_1, a_2, \ldots, a_n) \end{aligned}$$

Altogether we found $2D(a_1, a_2, \ldots, a_n) = 0$, if now $2 \in \operatorname{NZD}(R)$ is a non-zero divisor of R this can only mean $D(a_1, a_2, \ldots, a_n) = 0$, which is precisely the claim of (a). Thus we have returned to (a) and all three statements are equivalent.

Let us now assume R is some commutative ring and $\{ a_1, a_2, \ldots, a_n \} \subseteq R^n$ are linearly dependent. That is there are some $b_i \in R$, not all zero, such that

$$\sum_{i=1}^{n} b_i\, a_i \;=\; 0$$

For ease of notation let us assume $b_1 \neq 0$. As D is linear in every argument we can use this relation to evaluate the determinant of the a_i

$$\begin{aligned} b_1\, D(a_1, a_2, \ldots, a_n) &= D(b_1 a_1, a_2, \ldots, a_n) \\ &= D\left(-\sum_{i=2}^{n} b_i a_i, a_2, \ldots, a_n \right) \\ &= \sum_{i=2}^{n} -b_i D(a_i, a_2, \ldots, a_n) \end{aligned}$$

But as D is a determinant form and $D(a_i, a_2, \ldots, a_n)$ contains a_i twice for any $i \in 2 \ldots n$ property (a) implies $D(a_i, a_2, \ldots, a_n) = 0$. Therefore $b_1\, D(a_1, a_2, \ldots, a_n) = 0$ where $b_1 \neq 0$. If R is an integral domain we may conclude $D(a_1, a_2, \ldots, a_n) = 0$. For a general commutative ring $R \neq 0$ we find $b_1 \in \operatorname{ann}(D(a_1, a_2, \ldots, a_n))$ such that

$$\{ a_1, a_2 \ldots, a_n \} \text{ linearly dependent} \quad \Longrightarrow \quad \operatorname{ann}(D(a_1, a_2, \ldots, a_n)) \;\neq\; 0$$

Negating this implication we find the implication: If $\operatorname{ann}(D(a_1, a_2, \ldots, a_n)) = 0$ then $\{ a_1, a_2 \ldots, a_n \} \subseteq R^n$ must be linearly independent. □

Proof of (4.55):

(i) Let $A^* = (a^*_{i,j})$ that is if $A = (a_{i,j})$ then the coefficients of the transpose matrix are $a^*_{i,j} = a_{j,i}$ and

hence we find

$$\det(A^*) \;=\; \sum_{\sigma\in S_n} \operatorname{sgn}(\sigma) \prod_{i=1}^{n} a^*_{i,\sigma(i)} \;=\; \sum_{\sigma\in S_n} \operatorname{sgn}(\sigma) \prod_{i=1}^{n} a_{\sigma(i),i}$$

Let's say $j = \sigma(i)$ then $i = \sigma^{-1}(j)$ and we can replace the index $i \in 1\dots n$ by $j \in 1\dots n$ rewriting this expression, as

$$\det(A^*) \;=\; \sum_{\sigma\in S_n} \operatorname{sgn}(\sigma) \prod_{j=1}^{n} a_{j,\sigma^{-1}(j)}$$

Also note that $S_n \to S_n : \sigma \mapsto \sigma^{-1}$ is bijective and that $\operatorname{sgn}(\sigma^{-1}) = \operatorname{sgn}(\sigma)$, such that we may once again rewrite

$$\begin{aligned}\det(A^*) \;&=\; \sum_{\sigma^{-1}\in S_n} \operatorname{sgn}(\sigma^{-1}) \prod_{j=1}^{n} a_{j,\sigma^{-1}(j)} \\ &=\; \sum_{\pi\in S_n} \operatorname{sgn}(\pi) \prod_{j=1}^{n} a_{j,\pi(j)} \;=\; \det(A)\end{aligned}$$

(ii) In a first step we will prove $D(\mathbb{1}_n) = 1$, the proof multiplicative property will be postponed until after we have also proved (iv). Now clearly we have $\operatorname{col}_j(\mathbb{1}_n) = e_j$ where e_j is the Euclidean basis vector $e_j = (\delta_{i,j}) \in R^n$. Therefore

$$\det(\mathbb{1}_n) \;=\; \sum_{\sigma\in S_n} \operatorname{sgn}(\sigma)\, \delta_{1,\sigma(1)}\delta_{2,\sigma(2)} \dots \delta_{n,\sigma(n)}$$

Thus all the summands vanish, except for the one permutation σ that satisfies $\sigma(1) = 1$, $\sigma(2) = 2$ and so on until $\sigma(n) = n$. That is $\sigma = \mathbb{1}$ is the identity, which is of signum $\operatorname{sgn}(\mathbb{1}) = 1$. Hence $\det(\mathbb{1}_n) = 1$.

(iii) Let us first prove, that the determinant is a multi-linear form. To do this we fix any permutation $\sigma \in S_n$ and define $D_\sigma : (R^n)^n \to R$ by

$$D_\sigma(a_1, a_2, \dots, a_j) \;:=\; a_{\sigma^{-1}(1),1} a_{\sigma^{-1}(2),2} \dots a_{\sigma^{-1}(n),n}$$

where $a_j = (a_{1,j}, a_{2,j}, \dots, a_{n,j}) \in R^n$ as usual. That is D_σ picks one entry from every a_j and multiplies all these. In particular D_σ is linear in every argument, i.e. it is multi-linear. On the other hand the determinant is just

$$\det \;=\; \sum_{\sigma\in S_n} \operatorname{sgn}(\sigma)\, D_\sigma$$

an R-linear combination of these multi-linear maps - also refer to remark (4.53.(ii)) for more details on this. And thereby det clearly is multi-linear itself.

Next we will prove that $\det(A) = 0$ whenever A has two identical columns. For ease of notation let us assume $a_1 = a_2$, the general case uses precisely the same idea. Let $\tau := (1\,2) \in S_n$ be the transposition on 1 and 2, then clearly $\tau^{-1} = (2\,1) = \tau$. For a start, note that $a_1 = a_2$ in particular

means $a_{\sigma^{-1}(1),1} = a_{\sigma^{-1}(1),2}$ and likewise $a_{\sigma^{-1}(2),1} = a_{\sigma^{-1}(2),2}$. Therefore we get

$$\begin{aligned} D_\sigma(a_1, a_2, a_3, \ldots, a_n) &= a_{\sigma^{-1}(1),1} a_{\sigma^{-1}(2),2} \prod_{j=3}^{n} a_{\sigma^{-1}(j),j} \\ &= a_{\sigma^{-1}(1),2} a_{\sigma^{-1}(2),1} \prod_{j=3}^{n} a_{\sigma^{-1}(j),j} \\ &= a_{\sigma^{-1}\tau(2),2} a_{\sigma^{-1}\tau(1),1} \prod_{j=3}^{n} a_{\sigma^{-1}\tau(j),j} \\ &= a_{\sigma^{-1}\tau(1),1} a_{\sigma^{-1}\tau(2),2} \prod_{j=3}^{n} a_{\sigma^{-1}\tau(j),j} \\ &= D_{\tau\sigma}(a_1, a_2, a_3, \ldots, a_n) \end{aligned}$$

The latter, since $(\tau\sigma)^{-1} = \sigma^{-1}\tau^{-1} = \sigma^{-1}\tau$. That is, we have seen, that in case $a_1 = a_2$ we have the equality

$$D_\sigma(a_1, a_2, \ldots, a_n) = D_{\tau\sigma}(a_1, a_2, \ldots, a_n)$$

Recall that $A_n = \{\, \sigma \in S_n \mid \mathrm{sgn}(\sigma) = 1 \,\}$ and let us also denote $B_n = \{\, \pi \in S_n \mid \mathrm{sgn}(\pi) = -1 \,\}$ here. Then it is clear, that S_n is the disjoint union $S_n = A_n \cup B_n$ and hence we have

$$\det = \sum_{\sigma \in A_n} \mathrm{sgn}(\sigma)\, D_\sigma + \sum_{\pi \in B_n} \mathrm{sgn}(\pi)\, D_\pi$$

But clearly $S_n \longleftrightarrow S_n : \sigma \mapsto \tau\sigma$ is a bijection (this is true in any group). In this case however we have $\mathrm{sgn}(\tau\sigma) = -\mathrm{sgn}(\sigma)$, such that under this bijection A_n and B_n are interchanged: That is $\tau A_n = B_n$ and $\tau B_n = A_n$. Therefore $\pi \in B_n = \tau A_n$ means $\pi = \tau\sigma$ for some $\sigma \in A_n$. That is we may rewrite the sum over $\pi \in B_n$ in terms of

$$\det = \sum_{\sigma \in A_n} \mathrm{sgn}(\sigma)\, D_\sigma + \sum_{\sigma \in A_n} \mathrm{sgn}(\tau\sigma)\, D_{\tau\sigma}$$

Using $\mathrm{sgn}(\tau\sigma) = -\mathrm{sgn}(\sigma)$ and rejoining the sum we see, that the determinant can be evaluated by using even permutations only

$$\det = \sum_{\sigma \in A_n} \mathrm{sgn}(\sigma) \Big(D_\sigma - D_{\tau\sigma} \Big)$$

However, if $a_1 = a_2$ then we have argued above, that for this particular $A = (a_1, a_2, \ldots, a_n)$ we have $D_\sigma(A) = D_{\tau\sigma}(A)$ and therefore we find, that the determinant truly vanishes

$$\det(A) = \sum_{\sigma \in A_n} \mathrm{sgn}(\sigma) \Big(D_\sigma(A) - D_{\tau\sigma}(A) \Big) = \sum_{\sigma \in A_n} \mathrm{sgn}(\sigma) \cdot 0 = 0$$

(iv) Consider any n-tuples $a_j = (a_{i,j}) \in R^n$ where $j \in 1 \ldots n$ as well. If $e_i = (\delta_{i,j}) \in R^n$ denotes i-th the Euclidean base vector of size n then it is plain to see, that

$$a_j = \sum_{i=1}^{n} a_{i,j} e_i \in R^n$$

As we will do this with any a_j let use a separate index $\alpha(j)$ instead of i. Using this the above identity will now be written as

$$a_j \;=\; \sum_{\alpha(j)=1}^{n} a_{\alpha(j),j} e_{\alpha(j)}$$

By assumption D is a determinant form, in particular it is linear in each argument. Therefore we may expand all these a_j to find the following expression

$$\begin{aligned} D(a_1,\ldots,a_n) &= D\left(\sum_{\alpha(1)=1}^{n} a_{\alpha(1),1} e_{\alpha(1)},\ldots,\sum_{\alpha(n)=1}^{n} a_{\alpha(n),n} e_{\alpha(n)}\right) \\ &= \sum_{\alpha(1)=1}^{n}\cdots\sum_{\alpha(n)=1}^{n} a_{\alpha(1),1}\ldots a_{\alpha(n),n} D\left(e_{\alpha(1)},\ldots,e_{\alpha(n)}\right) \end{aligned}$$

If $\alpha(i)=\alpha(j)$ for some $i\neq j\in 1\ldots n$, then clearly $e_{\alpha(i)}=e_{\alpha(j)}$ such that by assumption (D is a determinant form) we then find $D(e_{\alpha(1)},\ldots,e_{\alpha(n)})=0$. Therefore only summands remain in which $i\neq j \implies \alpha(i)\neq\alpha(j)$, that is in which $\alpha\in S_n$ is a permutation

$$D(a_1,\ldots,a_n) \;=\; \sum_{\alpha\in S_n} a_{\alpha(1),1}\ldots a_{\alpha(n),n} D\left(e_{\alpha(1)},\ldots,e_{\alpha(n)}\right)$$

But since D is a determinant form, we have already seen in (4.54) that D also is alternating. In particular for any $\alpha\in S_n$ we find

$$D\left(e_{\alpha(1)},\ldots,e_{\alpha(n)}\right) \;=\; \operatorname{sgn}(\alpha) D\left(e_1,\ldots,e_n\right) \;=\; \operatorname{sgn}(\alpha) D(\mathbb{1}_n)$$

Altogether we have arrived at the following identity

$$\begin{aligned} D(a_1,\ldots,a_n) &= \sum_{\alpha\in S_n} a_{\alpha(1),1}\ldots a_{\alpha(n),n}\operatorname{sgn}(\alpha) D(\mathbb{1}_n) \\ &= D(\mathbb{1}_n)\sum_{\alpha\in S_n}\operatorname{sgn}(\alpha)\, a_{\alpha(1),1}\ldots a_{\alpha(n),n} \end{aligned}$$

Once again we use the bijection $S_n \longleftrightarrow S_n : \alpha\mapsto\alpha^{-1}$ to sum over $\sigma := \alpha^{-1}$ instead. As $\operatorname{sgn}(\sigma)=\operatorname{sgn}(\alpha^{-1})=\operatorname{sgn}(\alpha)$ we finally see that this sum turns into precisely the expression we are aiming at

$$\begin{aligned} D(a_1,\ldots,a_n) &= D(\mathbb{1}_n)\sum_{\sigma\in S_n}\operatorname{sgn}(\sigma)\, a_{\sigma^{-1}(1),1}\ldots a_{\sigma^{-1}(n),n} \\ &= D(\mathbb{1}_n)\cdot\det(a_1,\ldots,a_n) \end{aligned}$$

(ii) It remains to prove the homomorphism property of the determinant: To see this define $D:\operatorname{mat}_n(R)\to R$ by $D(B):=\det(AB)$. By definition of the multiplication of matrices we have $\operatorname{col}_i(AB)=A\operatorname{col}_i(B)$. That is (for any $b_1, b_2,\ldots,b_n\in R^n$) we have

$$D(b_1,b_2,\ldots,b_n) \;=\; \det(Ab_1,\, Ab_2,\,\ldots,\, Ab_n)$$

and hence all the maps $R^n\to R : b_k\mapsto D(b_1,b_2,\ldots,b_n)$ are just compositions of the linear maps

$R^n \to R^n : b_k \mapsto Ab_k$ and $R^n \to R : c_k \mapsto \det(c_1, c_2, \ldots, c_n)$ and therefore are linear themselves. In other words D is multi-linear. But also, whenever $b_j = b_k$ for some $j \neq k$, then $Ab_j = Ab_k$ such that $\det(Ab_1, Ab_2, \ldots, Ab_n) = 0$, which means that D even is a determinant form. Now by (iv) we get

$$\det(AB) \;=\; D(B) \;=\; D(\mathbb{1}_n) \cdot \det(B) \;=\; \det(A) \cdot \det(B)$$

(v) In a first step we will prove the Laplace expansion theorem by expanding along the bottom row. That is we start with a size $(n+1) \times (n+1)$ matrix $A = (a_{i,j}) \in \mathrm{mat}_{n+1}(R)$ and choose $p = n+1$. Then clearly

$$A_q \;:=\; A_{n+1,q} \;=\; \begin{pmatrix} a_{1,1} & a_{1,2} & \ldots & a_{1,q-1} & a_{1,q+1} & \ldots & a_{1,n+1} \\ a_{2,1} & a_{2,2} & \ldots & a_{2,q-1} & a_{2,q+1} & \ldots & a_{2,n+1} \\ \vdots & \vdots & & \vdots & \vdots & & \vdots \\ a_{n,1} & a_{n,2} & \ldots & a_{n,q-1} & a_{n,q+1} & \ldots & a_{n,n+1} \end{pmatrix}$$

We identify S_n with $\{\, \varrho \in of S_{n+1} S_{n+1} \mid \varrho(n+1) = n+1 \,\}$, a subgroup of S_{n+1}. Then by (1.12.(ii)) we know that S_{n+1} is the disjoint union

$$S_{n+1} \;=\; \bigcup_{q=1}^{n+1} \tau_q S_n$$

where τ_q is the transposition $\tau_q = (q \;\; n+1) \in S_{n+1}$. Thereby we can split the sum in the determinant of A into $n+1$ separate parts

$$\begin{aligned} \det(A) \;&=\; \sum_{\sigma \in S_{n+1}} \mathrm{sgn}(\sigma) \prod_{i=1}^{n+1} a_{i,\sigma(i)} \\ &=\; \sum_{q=1}^{n+1} \sum_{\varrho \in S_n} \mathrm{sgn}(\tau_q \varrho) \prod_{i=1}^{n+1} a_{i,\tau_q\varrho(i)} \end{aligned}$$

If $q = n+1$ then $\tau_q = \mathbb{1}$ and hence $\mathrm{sgn}(\tau_q\varrho) = \mathrm{sgn}(\varrho)$ if $q = n+1$ and $\mathrm{sgn}(\tau_q\varrho) = -\mathrm{sgn}(\varrho)$ in any other case. Also $\tau_q\varrho(i) = q$ if $i = n+1$, likewise $\tau_q\varrho(i) = n+1$ if $\varrho(i) = q$ and $\tau_q\varrho(i) = \varrho(i)$ in any other case. Therefore

$$\begin{aligned} \det(A) \;&=\; \sum_{\varrho \in S_n} \mathrm{sgn}(\varrho) \left(\prod_{i=1}^{n} a_{i,\varrho(i)} \right) a_{n+1,n+1} \\ &\quad - \sum_{q=1}^{n} \sum_{\varrho \in S_n} \mathrm{sgn}(\varrho) \left(\prod_{i=1}^{n} a_{i,\tau_q\varrho(i)} \right) a_{n+1,q} \end{aligned}$$

In the first part of this expression we clearly see the determinant of A_{n+1}. In the second part we see the determinant of the matrix A_{n+1} in which the q-th column has been replaced by the $(n+1)$-st colums

$$\sum_{\varrho \in S_n} \mathrm{sgn}(\varrho) \prod_{i=1}^{n} a_{i,\tau_q\varrho(i)}$$

$$= \det \begin{pmatrix} a_{1,1} & \dots & a_{1,q-1} & a_{1,n+1} & a_{1,q+1} & \dots & a_{1,n} \\ a_{2,1} & \dots & a_{2,q-1} & a_{2,n+1} & a_{2,q+1} & \dots & a_{2,n} \\ \vdots & & \vdots & \vdots & & \vdots & \\ a_{n,1} & \dots & a_{n,q-1} & a_{n,n+1} & a_{n,q+1} & \dots & a_{n,n} \end{pmatrix}$$

This matrix can be obtained from A_q by moving the last column of A_q one step up front $n-q$ times. As det is a determinant form and hence alternating, this means

$$\sum_{\varrho \in S_n} \operatorname{sgn}(\varrho) \prod_{i=1}^{n} a_{i,\tau_q \varrho(i)} \quad = \quad (-1)^{n-q} \det(A_q)$$

Altogether we have found the following expression for the determinant

$$\det(A) \quad = \quad \det(A_{n+1}) a_{n+1,n+1} - \sum_{q=1}^{n} (-1)^{n-q} \det(A_q) a_{n+1,q}$$

Since $(-1)^{2q} = 1$ we find $-(-1)^{n-q} = (-1)^{n-q+1}(-1)^{2q} = (-1)^{n+1+q}$ and if we recall $p = n+1$ this is $-(-1)^{n-q} = (-1)^{p+q}$. Therefore this identity can finally be written as

$$\begin{aligned} \det(A) &= a_{n+1,n+1} \det(A_{n+1}) + \sum_{q=1}^{n} (-1)^{p+q} a_{n+1,q} \det(A_q) \\ &= \sum_{q=1}^{n+1} (-1)^{p+q} a_{n+1,q} \det(A_q) \end{aligned}$$

That is we have proved the Laplace expansion theorem in case $p = n+1$. i.e. when expanding along the bottom row of A. For arbitrary $p \in 1 \dots n+1$ consider the matrix

$$B \quad := \quad \begin{pmatrix} \text{---} & \operatorname{row}_1(A) & \text{---} \\ & \vdots & \\ \text{---} & \operatorname{row}_{p-1}(A) & \text{---} \\ \text{---} & \operatorname{row}_{p+1}(A) & \text{---} \\ & \vdots & \\ \text{---} & \operatorname{row}_{n+1}(A) & \text{---} \\ \text{---} & \operatorname{row}_p(A) & \text{---} \end{pmatrix}$$

This matrix is obtained from A by moving the p-th row of A down one step, $n+1-p$ many times. Again - since det is alternating

$$\det(B) \quad = \quad (-1)^{n+1-p} \det(A)$$

On the other hand, we may expand B along the bottom row already. Doing so we find the following identity [note that $b_{n+1,q} = a_{p,q}$]

$$\det(B) \quad = \quad \sum_{q=1}^{n+1} (-1)^{n+1+q} a_{p,q} \det(B_q)$$

Thereby we also have $B_q = A_{p,q}$ by construction, such that joining these two equalities we find the following identity

$$(-1)^{n+1-p}\det(A) \;=\; \sum_{q=1}^{n+1}(-1)^{n+1+q}a_{p,q}\det(A_{p,q})$$

By multiplying with $(-1)^{n+1-p}$ and using $(-1)^{2n+2} = 1$ this is precisely the formula in the Laplace expansion theorem. So it oly remains to prove, that this formula also holds true when expanding along the q-th column of A. But this third step can be easily done by expanding the transpose A^* along the q-th row. Doing this we get

$$\det(A^*) \;=\; \sum_{p=1}^{n+1}(-1)^{q+p}a^*_{q,p}\det(A^*_{q,p})$$

By construction it is clear, that $(A^*)_{q,p} = (A_{p,q})^*$ and due to (i) these two matrices share the same determinant. The same is true for A and A^* of course, so rewriting $a^*_{q,p} = a_{p,q}$ we finally found the formula for expanding along a column, as well:

$$\det(A) \;=\; \sum_{p=1}^{n+1}(-1)^{p+q}a_{p,q}\det(A_{p,q})$$

(vi) By definition the determinant is just a combination of sums and products. Since α is a homomorphism of rings we have $\alpha(1_R) = 1_S$ such that for any permutation $\sigma \in S_n$ we have $\alpha(\mathrm{sgn}(\sigma)) = \mathrm{sgn}(\sigma) \in S$. And thereby we may compute

$$\begin{aligned}
\det\big(\alpha(A)\big) &= \sum_{\sigma\in S_n}\mathrm{sgn}(\sigma)\prod_{i=1}^{n}\alpha(a_{i,\sigma(i)}) \\
&= \sum_{\sigma\in S_n}\alpha(\mathrm{sgn}(\sigma))\alpha\left(\prod_{i=1}^{n}a_{i,\sigma(i)}\right) \\
&= \alpha\left(\sum_{\sigma\in S_n}\mathrm{sgn}(\sigma)\prod_{i=1}^{n}a_{i,\sigma(i)}\right) \\
&= \alpha\big(\det(A)\big)
\end{aligned}$$

□

Proof of (4.58):

(i) Let us abbreviate the block matrix by X and denote its entries by $x_{i,j}$ where $i, j \in 1\ldots(m+n)$, that is

$$X \;:=\; (x_{i,j}) \;=\; \begin{pmatrix} A & C \\ 0 & B \end{pmatrix}$$

Let us also introduce $I := 1\ldots m$ and $J := (m+1)\ldots(m+n)$ and let us finally identify S_m and S_n with certain subgroups of S_{m+n}:

$$S_m \;\cong_{\mathrm{g}}\; S'_m \;:=\; \{\,\varrho \in S_{m+n} \mid \forall\, j \in J : \varrho(j) = j\,\}$$

$$S_n \;\cong_{\mathrm{g}}\; S'_n \;:=\; \{\,\sigma \in S_{m+n} \mid \forall\, i \in I : \sigma(i) = i\,\}$$

If $\varrho \in S'_m$ and $\sigma \in S'_n$ then clearly $\mathrm{dom}(\varrho) \cap \mathrm{dom}(\sigma) \subseteq I \cap J = \emptyset$ and hence we have $\varrho\sigma = \sigma\varrho$. Now let us have a look at the determinant

$$\det(X) \;=\; \sum_{\pi \in S_{m+n}} \mathrm{sgn}(\pi) \prod_{i=1}^{m+n} x_{i,\pi(i)}$$

However, by the design of X, we have $x_{i,j} = 0$ whenever $i > m$ and $j \leq m$. That is $i \in J$ and $j \in I \implies x_{i,j} = 0$. In particular we find

$$\exists\, i \in J \,:\, \pi(i) \in I \quad\Longrightarrow\quad \prod_{i=1}^{m+n} x_{i,\pi(i)} \;=\; 0$$

Therefore the product vanishes unless $\pi(J) \subseteq J$ and since π is bijective this also implies $\pi(I) \subseteq I$. For such a π let us define $\varrho \in S'_m$ by $\varrho(i) := \pi(i)$ and $\varrho(j) := j$ where $i \in I$ and $j \in J$ respectively. Likewise define $\sigma \in S'_n$ by letting $\sigma(i) := i$ and $\sigma(j) := \pi(j)$. Then it is clear, that $\pi = \varrho\sigma$ such that

$$\begin{aligned}
\mathrm{sgn}(\pi) \prod_{i=1}^{m+n} x_{i,\pi(i)} &= \mathrm{sgn}(\varrho\sigma) \prod_{i=1}^{m} x_{i,\varrho(i)} \prod_{j=m+1}^{m+n} x_{i,\sigma(j)} \\
&= \left(\mathrm{sgn}(\varrho) \prod_{i=1}^{m} x_{i,\varrho(i)}\right)\left(\mathrm{sgn}(\sigma) \prod_{j=m+1}^{m+n} x_{j,\sigma(j)}\right) \\
&= \left(\mathrm{sgn}(\varrho) \prod_{i=1}^{m} a_{i,\varrho(i)}\right)\left(\mathrm{sgn}(\sigma) \prod_{j=1}^{n} b_{j,\sigma(j)}\right)
\end{aligned}$$

In the last step we used the identification $S_m = S'_m$ or - if we wanted to be formal - we would have to introduce $\sigma(j) := \sigma'(j+m) - m$ for this. As the product vanishes for all π that cannot be written in this form $\pi = \varrho\sigma$ the sum in truth only runs over

$$\begin{aligned}
\det(C) &= \sum_{\varrho \in S'_m} \sum_{\sigma \in S'_n} \mathrm{sgn}(\pi) \prod_{i=1}^{m+n} x_{i,\pi(i)} \\
&= \sum_{\varrho \in S'_m} \sum_{\sigma \in S'_n} \left(\mathrm{sgn}(\varrho) \prod_{i=1}^{m} a_{i,\varrho(i)}\right)\left(\mathrm{sgn}(\sigma) \prod_{j=1}^{n} b_{j,\sigma(j)}\right) \\
&= \left(\sum_{\varrho \in S'_m} \mathrm{sgn}(\varrho) \prod_{i=1}^{m} a_{i,\varrho(i)}\right)\left(\sum_{\sigma \in S'_n} \mathrm{sgn}(\sigma) \prod_{j=1}^{n} b_{j,\sigma(j)}\right) \\
&= \Big(\det(A)\Big)\Big(\det(B)\Big)
\end{aligned}$$

(ii) This is just a special case of (i) where $C = 0 \in \mathrm{mat}_{m,n}(R)$. So there really is nothing left to prove.

(iii) We will prove the statement for lower triangular matrices T. Upper triangular matrices are included, as they are the transpose of a lower triangular matrix. Recall that the determinant has been defined, as

$$\det(T) \;=\; \sum_{\sigma \in S_n} \mathrm{sgn}(\sigma) \prod_{i=1}^{n} t_{i,\sigma(i)}$$

Consider any permutation $\sigma \neq \mathbb{1}$ and let $i := \min\{\, j \in 1 \ldots n \mid \sigma(j) \neq j \,\}$. As i is minimal this

means $\sigma(h) = h$ for all $h < i$. If we had $\sigma(i) < i$ then for $h := \sigma(i)$ we had $\sigma(h) = h = \sigma(i)$ in contradiction to σ being injective. Hence we necessarily have $i < \sigma(i)$. But since T is a lower triangular matrix this means $t_{i,\sigma(i)} = 0$ and hence the entire product $\prod_i t_{i,\sigma(i)}$ vanishes. The only permutation which avoids this is $\sigma = \mathbb{1}$ with $\mathrm{sgn}(\mathbb{1}) = 1$. Hence the entire determinant boils down to

$$\det(T) \;=\; \sum_{\sigma=\mathbb{1}} \mathrm{sgn}(\sigma) \prod_{i=1}^{n} t_{i,\sigma(i)} \;=\; \prod_{i=1}^{n} t_{i,i}$$

□

Proof of (4.63):

(iv) Consider any $p, q \in 1 \ldots n$; if we scratch the p-th row and q-th column of A and transpose the rest, we obtain the same matrix, as if we had started with A^* and had scratched the q-th row and p-th column. Therefore we have

$$(A_{p,q})^* \;=\; (A^*)_{q,p}$$

Let now $c_{p,q}$ be the (p,q)-th entry of the cofactor matrix of A, that is $c_{p,q} = (-1)^{p+q}\det(A_{p,q})$. Likewise let $c^*_{q,p}$ be the (q,p)-th entry of the cofactor matrix of A^* that is $c^*_{q,p} = (-1)^{p+q}\det((A^*)_{q,p})$. As transposition does not change the determinant according to (4.55.(i)) we may compute

$$\begin{aligned} c^*_{q,p} &= (-1)^{p+q}\det\left((A^*)_{q,p}\right) \\ &= (-1)^{p+q}\det\left((A_{p,q})^*\right) \\ &= (-1)^{p+q}\det\left(A_{p,q}\right) \\ &= c_{p,q} \end{aligned}$$

That is the cofactor matrix $\mathrm{cof}(A^*)$ of the transpose is just the transpose matrix $\mathrm{cof}(A)^*$ of the cofactor matrix of A. And if this is true for the cofactor matrices, then it remains true for their transposes, the adjungate matrices.

(i) It might come as a surprise, but the proof of this theorem is purely computational. To begin with, fix $q \in 1 \ldots n$ and for $p \in 1 \ldots n$ let

$$c_p \;:=\; (-1)^{p+q}\det(A_{p,q})$$

Then by the Laplace expansion theorem (4.55.(v)) (expanding along the q-th column) it is clear that the c_p satisfy

$$\sum_{p=1}^{n} c_q a_{p,q} \;=\; \sum_{p=1}^{n} (-1)^{p+q} a_{p,q}\det(A_{p,q}) \;=\; \det(A)$$

On the other hand if $k \in 1 \ldots n$ with $k \neq q$ then by the same theorem we see that we expand the determinant along the q-th column of another matrix, namely

$$\sum_{p=1}^{n} c_q a_{p,k} \;=\; \det\begin{pmatrix} | & & | & | & | & & | \\ a_1 & \cdots & a_{q-1} & a_k & a_{q+1} & \cdots & a_n \\ | & & | & | & | & & | \end{pmatrix}$$

But since $k \in (1 \ldots q-1) \cup (q+1 \ldots n)$ this matrix contains the column a_k *twice*. That is the

determinant has to be zero, such that

$$\sum_{p=1}^{n} c_q a_{p,k} \;=\; 0 \quad \text{for } k \neq q$$

Let us now write out what the SLE $Ax = b$ means, explicitly. In fact this is precisely how the matrix multiplication has been defined

$$\begin{aligned} a_{1,1}x_1 + a_{1,2}x_2 + \cdots + a_{1,n}x_n &= b_1 \\ a_{2,1}x_1 + a_{2,2}x_2 + \cdots + a_{2,n}x_n &= b_2 \\ \vdots & \quad \vdots \\ a_{n,1}x_1 + a_{n,2}x_2 + \cdots + a_{n,n}x_n &= b_n \end{aligned}$$

We now multiply the first equation by c_1, the second equation by c_2 and do on until the last equation is multiplied by c_n

$$\begin{aligned} c_1a_{1,1}x_1 + c_1a_{1,2}x_2 + \cdots + c_1a_{1,n}x_n &= c_1b_1 \\ c_2a_{2,1}x_1 + c_2a_{2,2}x_2 + \cdots + c_2a_{2,n}x_n &= c_2b_2 \\ \vdots & \quad \vdots \\ c_na_{n,1}x_1 + c_na_{n,2}x_2 + \cdots + c_na_{n,n}x_n &= c_nb_n \end{aligned}$$

In a final step we sum up all these new equations, doing this we find the next equation, which is

$$\left(\sum_{p=1}^{n} c_p a_{p,1}\right) x_1 + \cdots + \left(\sum_{p=1}^{n} c_p a_{p,n}\right) x_n \;=\; \sum_{p=1}^{n} c_p b_p$$

As we have seen the sums over $c_p a_{p,k}$ vanish unless $k = q$. But in case $k = q$ the sum turns out to be $\det(A)$. That is in truth only

$$\det(A)\, x_q \;=\; \sum_{p=1}^{n} c_p b_p$$

But looking at the right hand side of this equation, we see, that this sum is just another expansion of another determinant along the q-th column, this time it is

$$\sum_{p=1}^{n} c_q b_k \;=\; \det\begin{pmatrix} | & & | & | & | & & | \\ a_1 & \cdots & a_{q-1} & b & a_{q+1} & \cdots & a_n \\ | & & | & | & | & & | \end{pmatrix}$$

(iii) Note that the coefficient c_p defined in (i) is just the (p,q)-th coefficient $c_{p,q} = (-1)^{p+q}\det(A_{p,q})$ of the cofactor matrix of A. So we have just shown in (i) that for any $k \in 1 \ldots n$ we find

$$\sum_{p=1}^{n} c_{p,q}\, a_{p,k} \;=\; \det(A) \cdot \delta_{k,q}$$

Let $a^{\#}_{p,q}$ be the (p,q)-th entry of the adjugate matrix $A^{\#}$ that is $a^{\#}_{q,p} = c_{p,q}$. Then the above equation

turns into

$$\sum_{p=1}^{n} a^{\#}_{q,p}\, a_{p,k} \;=\; \det(A)\cdot\delta_{k,q}$$

Note that the sum on the left hand side is just the scalar product of the q-th row of $A^{\#}$ with the k-th column a_k of A. But this is precisely the (q,k)-th entry of the product matrix $A^{\#}A$

$$\left[A^{\#}A\right]_{q,k} \;=\; \langle \mathrm{row}_q(A^{\#}, \mathrm{col}_k(A)\rangle \;=\; \det(A)\cdot\delta_{k,q}$$

And as this holds true for any k, $q \in 1\ldots n$ this is precisely $A^{\#}A = \det(A)\mathbb{1}_n$ in terms of coefficients. It remains to prove the other ordering $AA^{\#} = \det(A)\mathbb{1}_n$. But this can be done by using (iv) and going to the transpose matrix

$$\begin{aligned}
\left(AA^{\#}\right)^{*} &= \left(A^{\#}\right)^{*} A^{*} \;=\; \left(A^{*}\right)^{\#} A^{*} \\
&= \det\left(A^{*}\right)\mathbb{1}_n \;=\; \det(A)\mathbb{1}_n \\
\Longrightarrow\; AA^{\#} &= \left(\det(A)\mathbb{1}_n\right)^{*} \;=\; \det(A)\mathbb{1}_n
\end{aligned}$$

(ii) If A is invertible then by the homomorphism property of the determinant (4.55.(ii)) we see, that $\det(A)$ is invertible in R, as

$$1 \;=\; \det(\mathbb{1}_n) \;=\; \det(A^{-1}A) \;=\; \det(A^{-1})\cdot\det(A)$$

and from this we also see $\det(A^{-1}) = \det(A)^{-1}$ (as R is commutative). If conversely $\det(A) \in R^{*}$ is invertible, then we may define the matrix $B := \det(A)^{-1}\, A^{\#}$. Then from (iii) we see, that B is the inverse of A

$$\begin{aligned}
BA &= \det(A)^{-1}\, A^{\#}A \;=\; \det(A)^{-1}\det(A)\,\mathbb{1}_n \;=\; \mathbb{1}_n \\
AB &= A\det(A)^{-1}\, A^{\#} \;=\; \det(A)^{-1}\, AA^{\#} \\
&= \det(A)^{-1}\det(A)\,\mathbb{1}_n \;=\; \mathbb{1}_n
\end{aligned}$$

(v) If A is invertible (as a matrix), then so is $\det(A)$ (as a scalar) due to (ii). Then using (iii) it is easy to see, that $B := \det(A)^{-1}A$ is the inverse of $A^{\#}$ since

$$\begin{aligned}
BA^{\#} &= \det(A)^{-1}AA^{\#} \;=\; \det(A)^{-1}\det(A)\mathbb{1}_n \;=\; \mathbb{1}_n \\
A^{\#}B &= A^{\#}\det(A)^{-1}A \;=\; \det(A)^{-1}A^{\#}A \\
&= \det(A)^{-1}\det(A)\mathbb{1}_n \;=\mathbb{1}_n
\end{aligned}$$

That is we have proved $(A^{\#})^{-1} = B = \det(A)^{-1}A$ in case A is invertible. But then we may use (iii) on A^{-1} as well, to also obtain the identity $(A^{-1})^{\#}A^{-1} = \det(A^{-1})\mathbb{1}_n$. Multiplying this equation by A from the right we get

$$\left(A^{-1}\right)^{\#} \;=\; \det(A^{-1})A \;=\; \det(A)^{-1}A \;=\; \left(A^{\#}\right)^{-1}$$

On the other hand, since the determinant is linear in each of it's n arguments we get $\det(A^{\#}) =$

$\det(A)^{n-1}$ by dividing one $\det(A)$ from the following equation

$$\det(A)^n \;=\; \det(\det(A)\mathbb{1}_n) \;=\; \det(A^{\#}A) \;=\; \det(A^{\#})\cdot\det(A)$$

□

Proof of (4.65):

(i) We have already seen (a) $\iff$ (b) in (4.63.(ii)), next we will also prove (b) $\iff$ (e): To be invertible means that for any $b \in R^n$ there is precisely one $x = (x_1, x_2, \ldots, x_n) \in R^n$ such that $Ax = b$ (namely $x = A^{-1}b$). But this is $b = Ax = x_1c_1 + x_2c_2 + \cdots + x_nc_n$ which is just what we required for $\{\, c_1, c_2, \ldots, c_n \,\}$ being a basis.

Since $\det(A^*) = \det(A)$ and the columns of A^* are just the rows of A we also find that (f) is equivalent to $\det(A^*) \in R^*$ which is again equivalent to (b). Thus we also have (f) $\iff$ (b).

The implication (b) $\implies$ (c) and (d) is clear, so it remains to prove the converse implication only. If $AB = \mathbb{1}_n$ then due to (4.55.(ii)) we have $1 = \det(\mathbb{1}_n) = \det(AB) = \det(A)\cdot\det(B)$. As R is commutative this means $\det(A) \in R^*$ which is (a) and hence (b). The same argument also proves (d) $\implies$ (b) so we are done now.

(ii) By definition $\mathrm{kn}(A) \neq 0$ means, there is some $x = (x_1, x_2, \ldots, x_n) \in R^n$ such that $x \neq 0$ but $Ax = x_1c_1 + x_2c_2 + \cdots + x_nc_n = 0$. But this is just the R-linear dependency of $\{\, c_1, c_2, \ldots, c_n \,\}$. Thus we have finished (b) $\iff$ (c).

Next we will prove the equivalence of (a) and (c). Let us suppose (c) was untrue, i.e. there is some $x = (x_1, x_2, \ldots, x_n) \in R^n$ with $x \neq 0$ and $x_1c_1 + x_2c_2 + \cdots + x_nc_n = 0$. For ease of notation let us assume $x_1 \neq 0$, then - as the determinant is linear in every argument - we see

$$\begin{aligned} 0 \;&=\; \det(0, c_2, \ldots, c_n) \\ &=\; \det\left(\sum_{i=1}^{n} x_i c_i,\; c_2, \ldots, c_n\right) \\ &=\; \sum_{i=1}^{n} x_i \det\left(c_i, c_2, \ldots, c_n\right) \end{aligned}$$

But for any $i \neq 1$ in this sum the term $\det(c_i, c_2, \ldots, c_n)$ vanishes, as the column c_i appears in the determinant twice. Hence this sum boils down to the simple expression

$$0 \;=\; x_1 \det(c_1, c_2, \ldots, c_n) \;=\; x_1 \det(A)$$

Since $x_1 \neq 0$ by assumption and R is an integral domain this can only mean $\det(A) = 0$ such that we have proved (c) $\implies$ (a).

For the converse direction let us suppose that $\{\, c_1, c_2, \ldots, c_n \,\}$ is not linearly dependent, then we have to show that $\det(A) \neq 0$. To do this let us consider R to be a sub-ring of the quotient field $R \hookrightarrow E := \mathrm{QUOT}(R)$. Then $\{\, c_1, c_2, \ldots, c_n \,\}$ not only is R-linearly independent but even E-linearly independent: If we had

$$\frac{a_1}{b_1}c_1 + \frac{a_2}{b_2}c_2 + \ldots \frac{a_n}{b_n}c_n \;=\; 0$$

then we could multiply this equation by $b := b_1 b_2 \dots b_n \in R$ to find (note that $b \neq 0$, as all the $b_i \neq 0$ and $b/b_i \in R$ is a well-defined element of R) the following relation in R

$$a_1 \frac{b}{b_1} c_1 + a_2 \frac{b}{b_2} c_2 + \dots a_n \frac{b}{b_n} c_n \;=\; 0$$

As the c_i are R-linearly independent this would imply $a_i\, b/b_i = 0$ and hence $a_i = 0$ such that in turn $a_i/b_i = 0$ for any $i \in 1 \dots n$. Therefore $\{ c_1, c_2, \dots, c_n \}$ not only is E-linearly independent but, as E is a field, also an E-basis of E^n. Thus by (i).(e) we have $\det(A) \in E^* = E \setminus \{0\}$. In particular $\det(A) \neq 0$.

Since $\det(A^*) = \det(A)$ and the columns of A^* are just the rows of A we also find that (d) is equivalent to $\det(A^*) = 0$ which is again equivalent to (a). Thus we also have (d) $\iff$ (a).

□

Proof of (4.66):
If we abbreviate $x = (x_1, \dots, x_n)$ and $y = (y_1, \dots, y_n) \in M^n$ and generalize the matrix-vector multiplication to M by writing

$$Ax \;:=\; \begin{pmatrix} \sum_{j=1}^n a_{1,j}\, x_j \\ \vdots \\ \sum_{j=1}^n a_{n,j}\, x_j \end{pmatrix}$$

then by assumption we have $Ax = y$. Since M is an R-module all the operations of R and M are compatible. E.g. if a, $b \in R$ and $x \in M$ then we have $a(bx) = (ab)x$. Consequentially we find

$$A^\# y \;=\; A^\#(Ax) \;=\; (A^\# A)x \;=\; \det(A)x$$

according to (4.63.(iii)). By definition the (i,j)-th entry $a^\#_{i,j}$ of the adjugate matrix $A^\#$ is the (j,i)-th coefficient of the cofactor matrix $C = (c_{i,j})$ of A, which is $c_{i,j} = (-1)^{i+j} \det(A_{i,j})$. Therefore

$$\det(A)x \;=\; A^\# y \;=\; \begin{pmatrix} \sum_{i=1}^n a^\#_{1,i}\, y_i \\ \vdots \\ \sum_{i=1}^n a^\#_{n,i}\, y_i \end{pmatrix} \;=\; \begin{pmatrix} \sum_{i=1}^n c_{i,1}\, y_i \\ \vdots \\ \sum_{i=1}^n c_{i,n}\, x_i \end{pmatrix}$$

But these are precisely the n equations given in the claim. Finally, as thereby $\det(A)x_j \in \mathrm{Lh}\{ y_1, \dots, y_n \}$ for any $j \in 1 \dots n$ it is clear that the entire sub-module generated by the $\det(A)x_j$ is contained in

$$\det(A) \cdot \mathrm{Lh}\{ x_1, x_2, \dots, x_n \} \quad\subseteq\quad \mathrm{Lh}\{ y_1, y_2, \dots, y_n \}$$

□

Proof of (2.4):

(i) Let us abbreviate $\mathfrak{u} := \bigcup \mathcal{A}$, as $\mathcal{A}$ is non-empty there is some $\mathfrak{a} \in \mathcal{A}$. And as $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is an ideal we have $0 \in \mathfrak{a} \in \mathcal{A}$ and hence $0 \in \mathfrak{u}$. If now a, $b \in \mathfrak{u}$ then - by construction - there are $\mathfrak{a}$, $\mathfrak{b} \in \mathcal{A}$ such that $a \in \mathfrak{a}$ and $b \in \mathfrak{b}$. As $\mathcal{A}$ is a chain we may assume $\mathfrak{a} \subseteq \mathfrak{b}$ and hence $a \in \mathfrak{b}$, too. Therefore we get $a + b \in \mathfrak{b}$ and $-a$, $-b \in \mathfrak{b}$, such that $a + b$, $-a$ and $-b \in \mathfrak{u}$ again. And if finally $r \in R$ then $ra \in \mathfrak{a}$, such that $ra \in \mathfrak{u}$.

(ii) Let $\mathcal{Z} := \{ \mathfrak{b} \trianglelefteq_{\mathfrak{i}} R \mid \mathfrak{a} \subseteq \mathfrak{b} \neq R \}$, then $\mathcal{Z} \neq \emptyset$ since $\mathfrak{a} \in \mathcal{Z}$. Now let $\mathcal{A} \subseteq \mathcal{Z}$ be a chain in $\mathcal{Z}$, then by (i) we know that $\mathfrak{u} := \bigcup \mathcal{A} \trianglelefteq_{\mathfrak{i}} R$ is an ideal of R. Suppose $\mathfrak{u} = R$, then $1 \in \mathfrak{u}$ and hence there would be some $\mathfrak{b} \in \mathcal{A}$ with $1 \in \mathfrak{b}$. But as $\mathfrak{b} \trianglelefteq_{\mathfrak{i}} R$ is an ideal this would mean $\mathfrak{b} = R$ in contradiction to $\mathfrak{b} \in \mathcal{A} \subseteq \mathcal{Z}$. Hence we find $\mathfrak{u} \in \mathcal{Z}$ again. But by construction we have $\mathfrak{b} \subseteq \mathfrak{u}$ for any $\mathfrak{b} \in \mathcal{A}$, that is $\mathfrak{u}$ is an upper bound of $\mathcal{A}$. Hence by the lemma of Zorn there is some maximal element $\mathfrak{m} \in \mathcal{Z}^*$. It only remains to show that $\mathfrak{m}$ is maximal: as $\mathfrak{m} \in \mathcal{Z}$ it is an non-full ideal $\mathfrak{m} \neq R$. And if $R \neq \mathfrak{b} \trianglelefteq_{\mathfrak{i}} R$ is another non-full ideal with $\mathfrak{m} \subseteq \mathfrak{b}$ then $\mathfrak{a} \subseteq \mathfrak{m} \subseteq \mathfrak{b}$ implies $\mathfrak{b} \in \mathcal{Z}$. But now it follows that $\mathfrak{b} = \mathfrak{m}$ since $\mathfrak{m} \in \mathcal{Z}^*$, $\mathfrak{b} \in \mathcal{Z}$ and $\mathfrak{m} \subseteq \mathfrak{b}$.

(iii) Let $a \in R^*$ be a unit of R and $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} R$ be a maximal ideal. Then $a \notin \mathfrak{m}$, as else $1 = a^{-1}a \in \mathfrak{m}$ and hence $\mathfrak{m} = R$. From this we get $R^* \subseteq R \setminus \bigcup \mathrm{Smax}(R)$. For the converse inclusion we go to complements and prove $R \setminus R^* \subseteq \bigcup \mathrm{Smax}(R)$ instead. Thus let $a \in R$ be a non-unit $a \notin R^*$, then $1 \notin aR$ and hence $aR \neq R$. Thus by (i) there is a maximal ideal $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} R$ containing $a \in aR \subseteq \mathfrak{m} \subseteq \bigcup \mathrm{Smax}(R)$. Thus we also have $a \in \bigcup \mathrm{Smax}R$ which had to be proved.

(iv) If $R = 0$ is the zero-ring, then $R = \{0\}$ is the one and only ideal of R. But as this ideal is full, it cannot be maximal and hence $\mathrm{Smax}(R) = \emptyset$. If $R \neq 0$ then $\mathfrak{a} := \{0\}$ is a non-full ideal of R. Hence by (ii) there is a maximal ideal $\mathfrak{m} \in \mathrm{Smax}(R)$ containing it. In particular $\mathrm{Smax}(R) \neq \emptyset$.

(v) If R is a field and $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ is any ideal, then we distinguish two cases: If $\mathfrak{a} = 0$, then everything's fine. If $\mathfrak{a} \neq 0$ then there is some $a \in \mathfrak{a}$ with $a \neq 0$. Thus we have $1 = a^{-1}a \in \mathfrak{a}$ and thereby $\mathfrak{a} = R$. So the only ideal strictly larger than 0 is R itself and this makes 0 maximal. Note that $0 \neq R$, as in a field we have $0 \neq 1$.

If conversely 0 is a maximal ideal of R, then for any $a \in R$ with $a \neq 0$ we have $0 \subset aR \subseteq R$. That is aR is an ideal strictly larger, than 0. By maximality of 0 this means $aR = R$ and thereby there is some $b \in R$ such that $ab = 1$. This means a is a unit of R and as this is true for any $a \neq 0$, we found that R is a field.

□

Proof of (3.18):
Of course we will prove the claim using a Zornification: Let us define the collection of all proper sub-modules of N, that is

$$\mathcal{Z} \;:=\; \{ Z \leq_{\mathfrak{m}} N \mid P \subseteq Z, Z \neq N \}$$

As $P \in \mathcal{Z}$ this collection is non-empty. Also it is clear that $\mathcal{Z}$ is partially ordered under the inclusion relation "$\subseteq$". If now $(Z_i) \subseteq \mathcal{Z}$ is a chain in $\mathcal{Z}$ (that is a totally ordered subset), we take $Z := \bigcup_i Z_i$. Then $Z \leq_{\mathfrak{m}} N$ is a sub-module again: if $x, y \in Z$ then there are some $i, j \in I$ such that $x \in Z_i$ and $y \in Z_j$. As these sets are totally ordered we may assume $Z_i \subseteq Z_j$ without loss of generality. And hence $x + y \in Z_j \subseteq Z$ again. Also if $a \in R$, then $ax \in Z_i \subseteq Z$.

Now suppose $Z = N$, in particular for any $k \in 1 \ldots n$ we have $x_j \in N = Z$. Therefore for any $k \in 1 \ldots n$ there is some $i(k) \in I$ such that $x_k \in Z_{i(k)}$. As the Z_i are totally ordered we may single out the maximal element among $Z_{i(1)}, \ldots, Z_{i(n)}$. That is there is some $j \in I$ such that $Z_{i(k)} \subseteq Z_j$ for any $k \in 1 \ldots n$. In particular $x_k \in Z_{i(k)} \subseteq Z_j$ and as Z_j is an R-module we find $\mathrm{Lh}\{ x_1, \ldots, x_n \} \subseteq Z_j$. Now, as also $P \subseteq Z_j$ we get $N = P + \mathrm{Lh}\{ x_1, \ldots, x_n \} \subseteq Z_j \subseteq N$, that is $Z_j = N$. But this is in contradiction to

$Z_j \in \mathcal{Z}$, such that we necessarily have $Z \neq N$.

Let us subsume: we have found a sub-module $Z \leq_{\mathsf{m}} N$ with $Z \neq N$ and clearly also $P \subseteq Z$. That is $Z \in \mathcal{Z}$ again. But by construction Z is an upper bound (for any $i \in I$ we have $Z_i \subseteq Z$) of the chain (Z_i). Hence we may apply Zorn's lemma to find a maximal element $M \in \mathcal{Z}^*$. So by construction of $M \in \mathcal{Z}$ we have properties (1) and (2) of the claim. And if $M \subseteq Q \subseteq N$ for some sub-module Q, then either $Q = N$ or $Q \in \mathcal{Z}$ and hence $M = Q$, due to the maximality of M, and this is (3). □

Proof of (3.57):

(i) Because of (D1) (that is $x \in T \implies T \vdash x$) we have the obvious inclusions $S \subseteq T \subseteq \langle T \rangle$. That is we have $T \vdash S$. If now $x \in M$ with $S \vdash x$, then by (D2) we also get $T \vdash x$. And this is just a reformulation of the claim $\langle S \rangle \subseteq \langle T \rangle$.

(ii) We will first prove $\langle S \rangle = \bigcap \{ P \in \mathrm{sub}(M) \mid S \subseteq P \}$. For the inclusion "$\subseteq$" we are given any $x \in \langle S \rangle$. Then we need to show that for any $P \in \mathrm{sub}(M)$ with $S \subseteq P$ we get $x \in P$. As $P \in \mathrm{sub}(M)$ there is some $T \subseteq M$ with $P = \langle T \rangle$. Then $S \subseteq P$ translates into $S \subseteq \langle T \rangle$, which is $T \vdash S$. Together with $S \vdash x$ now property (D2) implies $T \vdash x$. And this is $x \in \langle T \rangle = P$, which had to be shown. Conversely for "$\supseteq$" we are given some $x \in M$ such that for any $P \in \mathrm{sub}(M)$ we get $S \subseteq P \implies x \in P$. Then we may simply choose $P := \langle S \rangle$, then $S \subseteq P$ is satisfied due to (D1). Thus by assumption on x we get $x \in P = \langle S \rangle$, which had to be shown.

Thus let us now prove $P = \langle P \rangle$, where we abbreviated $P := \langle S \rangle$. The inclusion "$\subseteq$" is clear by (D1) again. And by what we have shown, we have $\langle P \rangle = \bigcap \{ Q \in \mathrm{sub}(M) \mid P \subseteq Q \}$. But as $P \in \mathrm{sub}(M)$ with $P \subseteq P$ this trivially yields $\langle P \rangle \subseteq P$, the converse inclusion.

(iii) (a) $\implies$ (c): by assumption there is some $s \in S$ such that $S \setminus \{ s \} \vdash s$. Due to (D3) there is some finite subset $S_s \subseteq S \setminus \{ s \}$ such that $S_s \vdash s$. Now let $S_0 := S_s \cup \{ s \}$, then S_0 is finite again, as $\#S_0 = \#S_s + 1 < \infty$ and $S_0 \setminus \{ s \} = S_s$. In particular $S_0 \setminus \{ s \} \vdash s$, that is S_0 is $\vdash$depenedent. (c) $\implies$ (b): consider $S_0 \subseteq S \subseteq T$, by assumption there is some $s \in S_0$ such that $S_0 \setminus \{ s \} \vdash s$. However $S_0 \setminus \{ s \} \subseteq T \setminus \{ s \}$, such that by (i) we also get $T \setminus \{ s \} \vdash s$. That is T is $\vdash$dependent. (b) $\implies$ (a) finally is trivial, by letting $T := S$.

(iv) (a) $\implies$ (b): suppose S was $\vdash$dependent, that is there was some $s \in S$, such that $S \setminus \{ s \} \vdash s$. As $S \subseteq T$ we also have $S \setminus \{ s \} \subseteq T \setminus \{ s \}$, hence we find $S \setminus \{ s \} \vdash s$ due to (i). But as also $s \in S \subseteq T$ this is a contradiction to T being $\vdash$independent. (b) $\implies$ (c) is trivial (a finite subset is a subset). (c) $\implies$ (a): suppose there was some $x \in T$ such that $T \setminus \{ x \} \vdash x$. Then by (D3) there would be a finite subset $T_x \subseteq T \setminus \{ x \}$ such that $T_x \vdash x$. Now let $T_0 := T_x \cup \{ x \}$, then T_0 is finite again, as $\#T_0 = \#T_x + 1 < \infty$. Also $T_0 \setminus \{ x \} = T_x \vdash x$, that is T_0 is $\vdash$dependent in contradiction to (c).

(v) (b) $\implies$ (a): clearly $S \subset T := S \cup \{ x \}$, such that S is $\vdash$independent by assumption (a) and (iv). Now suppose we had $S \vdash x$, then clearly $T \setminus \{ x \} = S \vdash x$. That is T is $\vdash$dependent in contradiction to the assumption. (a) $\implies$ (b): if we had $x \in S$, then by property (D1) also $S \vdash x$, in contradiction to the assumption. Now suppose that $S \cup \{ x \}$ was $\vdash$dependent. That is there

would be some $s \in S \cup \{ x \}$ such that

$$S' \;:=\; \Big(S \cup \{ x \}\Big) \setminus \{ s \} \;\vdash\; s$$

We now distinguish two cases: (1) if $s = x$ then $S' = S$ and thereby we would get $S = S' \vdash s = x$, a contradiction to $S \nvdash x$. (2) if $s \neq x$ then $s \in S \cup \{ x \}$ implies $s \in S$. Now let $R := S \setminus \{ s \}$, that is $S = R \cup \{ s \}$ and $S' = (S \cup \{ x \}) \setminus \{ s \} = R \cup \{ x \}$. This again means

$$S' \setminus \{ x \} \;=\; R \;=\; S \setminus \{ s \}$$

As S is $\vdash$independent we now have $S' \setminus \{ x \} = S \setminus \{ s \} \nvdash s$. Because of $x \in S'$, $S' \vdash s$ and $S' \setminus \{ x \} \nvdash s$ property (D4) implies

$$S \;=\; \Big(S \setminus \{ s \}\Big) \cup \{ s \} \;=\; \Big(S' \setminus \{ x \}\Big) \cup \{ s \} \;\vdash\; x$$

This is a contradiction to $S \nvdash x$ again, thus in both cases we have derived a contradiction, that is $S \cup \{ x \}$ is $\vdash$independent, as claimed.

(vi) Let us abbreviate the chain's union by $T := \bigcup_i S_i$ and suppose T would be $\vdash$dependent. Then by (iii) there would be a finite subset $T_0 \subseteq T$, such that T_0 is $\vdash$dependent, already. Say $T_0 = \{ x_1, \ldots, n_n \}$, where for any $k \in 1 \ldots n$ we have $x_k \in S_{i(k)}$ for some $i(k) \in I$. As $\{ S_i \mid i \in I \}$ is totally ordered under $\subseteq$, so is the finite subset $\Big\{ S_{i(k)} \mid k \in 1 \ldots n \Big\}$. Without loss of generality we may assume, that $S_{i(n)}$ is the maximal element among the $S_{i(k)}$. Hence we find $x_k \in S_{i(k)} \subseteq S_{i(n)}$ for any $k \in 1 \ldots n$ and this again means $T_0 \subseteq S_{i(n)}$. Yet as T_0 was $\vdash$dependent this implies, that $S_{i(n)}$ is $\vdash$dependent (by (iii) again), a contradiction. Hence T is $\vdash$independent, as claimed.

(vii) Not surprisingly we will prove the claim using a zornification based on

$$\mathcal{Z} \;:=\; \{ P \subseteq M \mid S \subseteq P \subseteq T,\ P \text{ is } \vdash\text{independent} \}$$

Of course $\mathcal{Z}$ is non-empty, as $S \in \mathcal{Z}$, and it is partially ordered under the inclusion relation $\subseteq$. Due to (vi) any ascending chain (S_i) admits an upper bound, namely $T := \bigcup_i S_i \in \mathcal{Z}$. Thus by the lemma of Zorn $\mathcal{Z}$ contains a maximal element B. Because of $B \in \mathcal{Z}$ we have $S \subseteq B \subseteq T$ and B is $\vdash$independent. Now suppose there was some $x \in T$ with $B \nvdash x$. However, as B is $\vdash$independent and $B \nvdash x$, we find by (v) that even $B \cup \{ x \}$ is $\vdash$independent. But as $x \notin B$ we have $B \subset B \cup \{ x \} \subseteq T$. Thus we have found a contradiction to the maximality of B. This contradiction can only be solved, if $T \subseteq \langle B \rangle$. And using (i) and (ii) we thereby get $M = \langle T \rangle \subseteq \langle \langle B \rangle \rangle = \langle B \rangle \subseteq M$. Altogether B is $\vdash$ independent and $M = \langle B \rangle$ - it is a $\vdash$basis.

(viii) First suppose $x = b$, then $B' = B$ and hence there is nothing to show. Thus assume $x \neq b$. The proof now consists of two parts: (1) as $B \setminus \{ b \} \subseteq B' \subseteq \langle B' \rangle$ and $B' \vdash b$ by assumption, we have $B = (B \setminus \{ b \}) \cup \{ b \} \subseteq \langle B' \rangle$. And thereby $M = \langle B \rangle \subseteq \langle \langle B' \rangle \rangle = \langle B' \rangle \subseteq M$, according to (ii). That is $M = \langle B' \rangle$. (2) as $B \setminus \{ b \} \subseteq B$ is a subset and B is $\vdash$independent, so is $B \setminus \{ b \}$, due to (iv). Now suppose $B \setminus \{ b \} \vdash x$, then we would get $B' = (B \setminus \{ b \}) \cup \{ x \} \subseteq \langle B \setminus \{ b \} \rangle$. And hence $b \in M = \langle B' \rangle \subseteq \langle \langle B \setminus \{ b \} \rangle \rangle = \langle B \setminus \{ b \} \rangle$, according to (1) and (ii) once more. But this is $B \setminus \{ b \} \vdash b$ in contradiction to the $\vdash$independence of B. Thus we have $B \setminus \{ b \} \nvdash x$, as $B \setminus \{ b \}$

also is $\vdash$independent (v) now implies, that $B' = (B \setminus \{ b \}) \cup \{ x \}$ is $\vdash$independent. Combining (1) and (2) we found that B' is a $\vdash$basis.

(ix) (a) $\implies$ (b): $M = \langle B \rangle$ is clear by definition of a $\vdash$basis. Now consider some subset $S \subset B$, that is there is some $x \in B$, with $x \notin S$. As B is $\vdash$independent and $x \in B$ we get $B \setminus \{ x \} \nvdash x$, in other words $x \notin \langle B \setminus \{ x \} \rangle$. And as $S \subseteq B \setminus \{ x \}$ (i) implies $x \notin \langle S \rangle$. In particular $\langle S \rangle \neq M$, as claimed.

(b) $\implies$ (a): as $M = \langle B \rangle$ by assumption it only remains to verify the $\vdash$independence of B. Thus assume, there was some $x \in B$ such that $S := B \setminus \{ x \} \vdash x$. As $S \subseteq \langle S \rangle$ and $x \in \langle S \rangle$, we have $B = S \cup \{ x \} \subseteq \langle S \rangle$. And thereby $M = \langle B \rangle \subseteq \langle \langle S \rangle \rangle = \langle S \rangle \subseteq M$ according to (ii). This is $M = \langle S \rangle$ even though $S \subset B$, a contradiction.

(ix) (a) $\implies$ (c): suppose B is a $\vdash$basis, that by definition B already is $\vdash$independent. Thus suppose $B \subset S$, that is we may choose some $s \in S \setminus B$. As $s \in M = \langle B \rangle$ we get $B \vdash s$. And as $B \subseteq S \setminus \{ s \}$ (i) also yields $S \setminus \{ s \} \vdash s$. That is S is $\vdash$ dependent, as claimed.

(c) $\implies$ (a): as B is assumed to be $\vdash$independent, it remains to show $M = \langle B \rangle$. Thus suppose we had $\langle B \rangle \subset M$, that is there was some $s \in M$ such that $B \nvdash s$. Then by (v) we find that $S := B \cup \{ s \}$ is independent, as well - a contradiction.

(x) Let us abbreviate $B' := (B \setminus A) \cup A'$, then we first prove, that B' also generates M. So consider any $x \in M$, as B is a basis we have $B \vdash x$ and by (D2) there are finitely many elements $a_1, \ldots, a_m \in A$ and $b_1, \ldots, b_n \in B \setminus A$ such that

$$\{ a_1, \ldots, a_m, b_1, \ldots, b_n \} \vdash x$$

For any $i \in 1 \ldots m$ we have $a_i \in A \subseteq \langle A \rangle = \langle A' \rangle$ such that $A' \vdash a_i$. And as this is true for any i we have $A' \vdash \{ a_i, \ldots, a_m \}$. According to (i) in particular $A' \cup \{ b_1, \ldots, b_n \} \vdash \{ a_i, \ldots, a_m \}$. But as $b_i \in A' \cup \{ b_1, \ldots, b_n \}$ we also get $A' \cup \{ b_1, \ldots, b_n \} \vdash \{ b_1, \ldots, b_n \}$ by (D1). Altogether

$$A' \cup \{ b_1, \ldots, b_n \} \vdash \{ a_1, \ldots, a_m, b_1, \ldots, b_n \}$$

We now use property (D3) to find $A' \cup \{ b_1, \ldots, b_n \} \vdash x$. By (i) again, that is $B' = A' \cup (B \setminus A) \vdash x$ and as this is true for any $x \in M$ we have $B' \vdash M$ which makes B' a generating set of M.

It remains to prove, that B' also is $\vdash$independent. Suppose not, then by (iii) there would be a finite subset of B' that is $\vdash$dependent. In this case there are some $a'_1, \ldots, a'_m \in A'$ and $b_1, \ldots, b_n \in B \setminus A$ such that $\{ a'_1, \ldots, a'_m, b_1, \ldots, b_n \}$ was $\vdash$dependent. We choose $n \in \mathbb{N}$ minimal such that

$$\exists\, b_1, \ldots, b_n \in B \setminus A \ : \ A' \cup \{ b_1, \ldots, b_n \} \quad \text{is } \vdash\text{dependent}$$

Clearly $n = 0$ is absurd, as this would mean that A' is $\vdash$dependent, which we assumed not to be the case. So $n \geq 1$, but as n is minimal, this means $A' \cup \{ b_2, \ldots, b_n \}$ is $\vdash$independent. Now from $A' \cup \{ b_1, \ldots, b_n \}$ being $\vdash$dependent (v) yields

$$A' \cup \{ b_2, \ldots, b_n \} \vdash b_1$$

Again for any $a' \in A'$ we have $a' \in A' \subseteq \langle A' \rangle = \langle A \rangle$ such that $A \vdash a'$. And as this is true for any $a' \in A'$ even $A \vdash A'$. In particular $A \cup \{ b_2, \ldots, b_n \} \vdash A'$ by (i) again. As before by (D1) $b_j \in A \cup \{ b_2, \ldots, b_n \}$ implies $A \cup \{ b_2, \ldots, b_n \} \vdash b_j$ for any $j \in 2 \ldots n$. Together we have

$$A \cup \{ b_2, \ldots, b_n \} \ \vdash \ A' \cup \{ b_2, \ldots, b_n \}$$

so we find $A \cup \{ b_2, \ldots, b_n \} \vdash b_1$ according to (D3). In particular $A \cup \{ b_1, b_2, \ldots, b_n \}$ is $\vdash$dependent in contradiction to the larger set B being $\vdash$independent. This contradiction can only be solved by B' being $\vdash$independent and hence B is a basis of M.

(xi) Let us denote $m := |A|$ and $n := |B|$, then we need to show $m = n$. In the proof we will have to distinguish two cases: (I) m or n is finite and (II) both m and n are infinite. We will deal with (I) in the following steps (1) to (4), whereas (II) will be treated in (5)

(1) Without loss of generality we may assume $m \leq n$ (interchanging A and B if not). Then M is finite by assumption (I), let us denote the elements of A by $A = \{ x_1, \ldots, x_m \}$. Thereby let us assume that $x_1, \ldots, x_k \notin B$ and $x_{k+1}, \ldots, x_m \in B$ for some $k \in \mathbb{N}$ [note that for $k = 0$ this is $A \subseteq B$ and for $k = m$ this is $A \cap B = \emptyset$]. In the case $k = 0$ we may skip steps (2), (3) and let $A^{(k)} := A$, immediately proceeding with (4).

(2) As A is a $\vdash$basis of M, it is a minimal $\vdash$generating subset, by (ix). That is $\langle \{ x_2, \ldots, x_m \} \rangle \neq M = \langle B \rangle$. Hence there is some point $b \in B$ such that $b \notin \langle \{ x_2, \ldots, x_m \} \rangle$ [as else $B \subseteq \langle \{ x_2, \ldots, x_m \} \rangle$ and hence $M = \langle B \rangle \subseteq \langle \langle \{ x_2, \ldots, x_m \} \rangle \rangle = \langle \{ x_2, \ldots, x_m \} \rangle$, according to (ii), a contradiction]. For this $b \in B$ let us define

$$A' \ := \ \Big(A \cup \{ b \} \Big) \setminus \{ x_1 \} \ = \ \{ b, x_2, \ldots, x_m \}$$

Then A' is $\vdash$independent [as A is $\vdash$independent, the same is true for $\{ x_2, \ldots, x_m \}$. And due to $\{ x_2, \ldots, x_m \} \nvdash b$ (v) implies, that A' is independent]. Next we find that $A' \vdash x_1$ [because if we had $A' \nvdash x_1$ then - using (v) and the fact that A' is $\vdash$independent - $A' \cup \{ x_1 \}$ would be $\vdash$independent, too. However this is untrue, as $(A' \cup \{ x_1 \}) \setminus \{ b \} = A \vdash b$]. Therefore A' even is a $\vdash$basis [as $A' \vdash x_1$ we have $x_1 \in \langle A' \rangle$ and clearly $A \setminus \{ x_1 \} \subseteq \langle A' \rangle$, such that $A = (A \setminus \{ x_1 \}) \cup \{ x_1 \} \subseteq \langle A' \rangle$. Combined with (ii) this yields $M = \langle A \rangle \subseteq \langle \langle A' \rangle \rangle = \langle A' \rangle \subseteq M$, that is $\langle A \rangle = M$ and the $\vdash$independence of A' has already been shown].

(3) In (2) we have replaced $x_1 \in A$ by some $b \in B$ to obtain another $\vdash$basis $A' := (A \cup \{ b \}) \setminus \{ x_1 \} = \{ b, x_2, \ldots, x_k \}$. That is: venturing from A to A' we have increased the number of elements in $A' \cap B$ by 1 (with respect to $A \cap B$). Iterating this process k times we establish a $\vdash$basis $A^{(k)} = \{ b_1, \ldots, b_k, x_{k+1}, \ldots, x_m \} \subseteq B$.

(4) From the construction it is clear, that $|A'| \leq m \leq n = |B|$. On the other hand - as B is a $\vdash$basis, $A' \subseteq B$ and $M = \langle A' \rangle$ - item (ix) now implies that $A' = B$. And thereby $n = |B| = |A'| \leq m$, as well. Together this is $m = n$ as claimed.

(5) It remains to regard case (II), that is m and N are both infinite. As $B \subseteq M = \langle A \rangle$ we obviously have $A \vdash b$ for any $b \in B$. Thus by property (D3) there is a subset $A_b \subseteq A$ such

that $\#A_b < \infty$ is finite and $A_b \vdash b$ already. Now let

$$A^* \;:=\; \bigcup_{b\in B} A_b \quad\subseteq\quad A$$

Then for any $b \in B$ we have $A_b \subseteq A^*$ and hence $A^* \vdash b$, due to (i). That is $b \in \langle A^* \rangle$ for any $b \in B$ and hence $B \subseteq \langle A^* \rangle$. Thus by (i) and (ii) again we get $M = \langle B \rangle \subseteq \langle \langle A^* \rangle \rangle = \langle A^* \rangle \subseteq M$, such that $M = \langle A^* \rangle$. Now, as A is a $\vdash$basis, if we had $A^* \subset A$, then (ix) would yield $M \neq \langle A^* \rangle$, a contradiction. This is $A = A^*$ and hence we may compute

$$|A| \;=\; \left| \bigcup_{b\in B} A_b \right| \;\leq\; \sum_{b\in B} |A_b| \;\leq\; |B \times \mathbb{N}| \;=\; |B|$$

Hereby $|B \times \mathbb{N}| = |B|$ holds true, as B was assumed to be infinite. Thus we have found $m \leq n$ and by interchanging the roles of A and B we also find $n \leq m$, which had to be shown.

(xii) As S is independent, $S \subseteq M$ and $M = \langle M \rangle$ we get from (vii) that there is some $\vdash$basis A of M, with $S \subseteq A \subseteq M$. Thus by (x) we already obtain the claim from $|S| \leq |A| = |B|$. Likewise, as T generates M and $\emptyset$ is independent (trivially), we get from (vii) that there is some $\vdash$basis A of M, with $\emptyset \subseteq A \subseteq T$. Thus by (x) we already obtain the claim from $|B| = |A| \leq |T|$.

(xiii) (b) $\implies$ (a) has already been shown in (x), thus it only remains to verify (a) $\implies$ (b): thus consider any $\vdash$independent subset $S \subseteq M$ with $|S| = |B|$. As before [S is independent, $S \subseteq M$ and $M = \langle M \rangle$ now use (vii)] there is some $\vdash$basis A of M, with $S \subseteq A \subseteq M$. Thus by (x) we find $|B| = |S| \leq |A| = |B|$. That is $|A| = |S| = |B| < \infty$ which was assumed to be finite. In particular S is a subset of the finite set A, with the same number of elements $\#S = \#A$. Clearly this means $S = A$ and in particular S is a $\vdash$basis of M.

□

Proof of (3.60):

(i) Trivially $\emptyset$ is R-linearly independent and $\emptyset$ also generates $\{0\}$, as $\{0\}$ is the one and only submodule of $\{0\}$. Together $\emptyset$ is an R-basis of $\{0\}$ and in particular $\mathrm{rank}\{0\} = 0$. Conversely if $\mathrm{rank} M = 0$, then by definition $M = \langle \emptyset \rangle_{\mathsf{m}} = \{0\}$.

(ii) If $M = P + \langle X \rangle_{\mathsf{m}}$ then as $P \subseteq Q$ we also get $M = Q + \langle X \rangle_{\mathsf{m}}$.

(iii) First suppose $\mathfrak{a} = aR$ is principal. If $a = 0$, then $\mathfrak{a} = 0$, which is a free R-module, with basis $\emptyset$. And if $a \neq 0$, then $\{\, a \,\}$ is an R-basis of $\mathfrak{a}$. It generates $\mathfrak{a}$, as $\langle \{\, a \,\} \rangle_{\mathsf{m}} = aR = \mathfrak{a}$ and it is R-linearly independent, as $ba = 0 \implies b = 0$ (as $a \neq 0$ and R is an integral domain). Conversely suppose $\mathfrak{a}$ is free, with basis $B \subseteq \mathfrak{a}$. If $B = \emptyset$, then $\mathfrak{a} = \langle \emptyset \rangle_{\mathsf{m}} = 0$, which is principal $\mathfrak{a} = 0 = R0$. And if we had $\#B \geq 2$, then we could choose some $b_1, b_2 \in B$. But this would yield $b_2 b_1 + (-b_1) b_2 = 0$ (as R is commutative) and hence B would not be R-linearly independent. Thus it only remains $\#B = 1$, say $B = \{\, a \,\}$ and hence $\mathfrak{a} = \langle B \rangle_{\mathsf{m}} = aR$ is principal.

(iv) We have to prove that E is an R-linearly independent set, that also R-generates $R^{\oplus I}$. Thus suppose we are given any $x = (x_i) \in R^{\oplus I}$. Let us denote $\Omega := \{\, i \in I \mid x_i \neq 0 \,\}$, then Ω is finite,

by definition of $R^{\oplus I}$. And hence we get $x = \sum_{i\in\Omega} x_i e_i \in \langle \mathcal{E} \rangle_{\mathfrak{m}}$. Therefore $\mathcal{E}$ generates $R^{\oplus I}$ as an R-module. For the R-linear independence we have $\sum_{i\in\Omega} a_i e_i = 0$ for some finite subset $\Omega \subseteq I$ and some $a_i \in R$. We now compare the coefficients of 0 and $\sum_{i\in\Omega} a_i e_i$. Hereby for any $i \in \Omega$ the i-th coefficient of $0 \in R^{\oplus I}$ is $0 \in R$. And the i-th coefficient of $\sum_{i\in\Omega} a_i e_i$ is a_i. That is $a_i = 0$ for any $i \in \Omega$ and this means that $\mathcal{E}$ is R-linearly independent.

□

Proof of (3.61):

(i) (D1): consider an arbitrary subset $X \subseteq M$ and $x \in X$. Then we find $X \vdash x$ simply by choosing $n := 1$, $x_1 := x$ and $a_1 := 1$, as in this case $a_1 x_1 = 1x = x$. (D2): consider any two subsets X, $Y \subseteq M$ such that $Y \vdash X$ and $X \vdash x$. Thus by definition there are some $n \in \mathbb{N}$, $x_i \in X$ and $a_i \in R$ such that $x = a_1 x_1 + \cdots + a_n x_n$. But as $x_i \in X$ and $Y \vdash X$ there also are some $m(i) \in \mathbb{N}$, $y_{i,j} \in Y$ and $b_{i,j} \in R$ such that $x_i = b_{i,1} y_{i,1} + \cdots + b_{i,m(i)} y_{i,m(i)}$. Combining these equations, we find

$$x \;=\; \sum_{i=1}^{n} a_i x_i \;=\; \sum_{i=1}^{n} \sum_{j=1}^{m(j)} a_i b_{i,j} y_{i,j}$$

In particular this identity yields $Y \vdash x$, which had to be shown. (D3): consider an arbitrary subset $X \subseteq M$ and $x \in M$ such that $X \vdash x$. Again this means $x = a_1 x_1 + \cdots + a_n x_n$ for sufficient $x_i \in X$ and $a_i \in R$. Now let $X_0 := \{ x_1, \ldots, x_n \} \subseteq X$. Then X_0 clearly is a finite set and $X_0 \vdash x$, by construction. As (D1), (D2) and (D3) are satisfied, we already obtain (iii), (iv) and (v) from (3.57).

(ii) The identity $\langle X \rangle = \{ x \in M \mid X \vdash x \} = \mathrm{Lh}_R(X)$ is obvious from the definitions of the relation $\vdash$ and the linear hull $\mathrm{Lh}_R(X)$. And the identity $\mathrm{Lh}_R(X) = \langle X \rangle_{\mathfrak{m}}$ has already been shown in (3.12).

(vi) (b) $\Longrightarrow$ (a): we first prove that B is a *generating system* of M: Thus consider any $x \in M$, by assumption there is some $(x_b) \in R^{\oplus B}$ such that $x = \sum_b x_b b$. Now let $\Omega := \{ b \in B \mid x_b \neq 0 \}$. Then $\Omega \subseteq B$ is finite and we further get

$$x \;=\; \sum_{b\in B} x_b b \;=\; \sum_{b\in\Omega} x_b b \;\in\; \mathrm{Lh}_R(B)$$

As x has been arbitrary that is $M \subseteq \mathrm{Lh}_R(B) = \langle B \rangle_{\mathfrak{m}}$. Let us now prove that B also is *R-linear independent*: thus consider some finite subset $\Omega \subseteq B$ and some $a_b \in R$ (where $b \in \Omega$) such that $\sum_{b\in\Omega} a_b b = 0$. Then for any $b \in B \setminus \Omega$ we let $a_b := 0$ and thereby obtain

$$\sum_{b\in B} a_b b \;=\; \sum_{b\in\Omega} a_b b \;=\; 0 \;=\; \sum_{b\in B} 0 b$$

Due to the uniqueness of this representation (of $0 \in M$) we find $a_b = 0$ for any $b \in B$. And in particular $a_b = 0$ for any $b \in \Omega$. By definition this means that B truly is R-linearly independent.

(vi) (a) $\Longrightarrow$ (b): *Existence*: consider any $x \in M$, as $M = \langle B \rangle_{\mathfrak{m}} = \mathrm{Lh}_R(B)$ there are a finite subset $\Omega \subseteq B$ and $a_b \in R$ (where $b \in \Omega$) such that $x = \sum_{b\in\Omega} a_b b$. Now let $x_b := a_b$ if $b \in \Omega$ and $x_b := 0$ if $b \in B \setminus \Omega$. Then $(x_b) \in R^{\oplus B}$ and we also get

$$x \;=\; \sum_{b\in\Omega} a_b b \;=\; \sum_{b\in B} x_b b$$

Uniqueness: consider any two (x_b), $(y_b) \in R^{\oplus B}$ representing the same element $\sum_b x_b b = \sum_b y_b b$. Now let $\Omega := \{\, b \in B \mid x_b \neq 0, \text{ or } y_b \neq 0 \,\}$. Then $\Omega \subseteq B$ is finite and we clearly get

$$0 \;=\; \sum_{b\in B}(x_b - y_b)b \;=\; \sum_{b\in\Omega}(x_b - y_b)b$$

Yet as B is R-linearly independent, this means $x_b - y_b = 0$ for any $b \in \Omega$ and hence $x_b = y_b$ for any $b \in B$ (if $b \notin \Omega$, then $x_b = 0 = y_b$). But this already is the uniqueness of the representation.

□

Proof of (3.64):
As (3.66) is a direct continuation of (3.64) this proof deals with both of these propositions simultaneously. Hence the odd enumeration of the statements in (3.66) that began by (vii) instead of (i).

(i) By (3.61) $\vdash$ already satisfies (D1), (D2) and (D3). Thus it only remains to prove (D4) and we will already do this in the stronger form given in the claim. That is we consider $x \in X$ and $X \vdash y$. By definition of $\vdash$ this is $y = a_1x_1 + \cdots + a_nx_n$ for some $a_i \in S$ and $x_i \in X$. Of course we may drop any summand with $a_i = 0$ and hence assume $a_i \neq 0$ for any $i \in 1\ldots n$. As $y \neq 0$ we still have $n \geq 1$. Now let $X' := (X \setminus \{\, x \,\}) \cup \{\, y \,\}$ (that is we have to show $X' \vdash x$) and distinguish two cases: (1) if $x \notin \{\, x_1, \ldots, x_n \,\}$ then $\{\, x_1, \ldots, x_n \,\} \subseteq X \setminus \{\, x \,\} \subseteq X'$ and in particular $X' \vdash x$. (2) if $x \in \{\, x_1, \ldots, x_n \,\}$ we may assume $x = x_1$ without loss of generality. Now let $b_i := -a_1^{-1}a_i \in S$ (for any $i \in 2\ldots n$), then $x = x_1 = a_1^{-1}a_1x_1 = b_2x_2 + \cdots + b_nx_n$. And as $\{\, x_2, \ldots, x_n \,\} \subseteq X \setminus \{\, x \,\} \subseteq X'$ this implies $X' \vdash x$. Thus we have proved the claim in both cases. From this property we can easily derive (D4): suppose $x \in X$, $X \vdash y$ and $X \setminus \{\, x \,\} \nvdash y$. Then $y \neq 0$, as even $\emptyset \vdash 0$ and hence $X \setminus \{\, x \,\} \vdash y$. Thus we may apply this property to find $X' \vdash x$, which had to be shown.

(ii) (b) $\Longrightarrow$ (a): suppose there was some $x \in X$ such that $X \setminus \{\, x \,\} \vdash x$. So by definition there would be some elements $x_i \in X \setminus \{\, x \,\}$ and $a_i \in S$ (where $i \in 1\ldots n$) such that $x = a_1x_1 + \cdots + a_nx_n$. Now let $x_0 := x$ and $a_0 := -1$, then we get $x_i \in X$ for any $i \in 1\ldots n$ and also $a_0x_0 + a_1x_1 + \cdots + a_nx_n = 0$. But as $a_0 \neq 0$ this means that X is S-linear dependent, a contradiction. Thus there is no such $x \in X$ and this is the $\vdash$independence of X.

(a) $\Longrightarrow$ (b): suppose there were some (pairwise distinct) elements $x_i \in X$ and $a_i \in R$ (where $i \in 1\ldots n$) such that (without loss of generality) $a_1 \neq 0$ and $a_1x_1 + \cdots + a_nx_n = 0$. As $a_1 \neq 0$ we may let $b_i := -a_1^{-1}a_i$ for $i \in 2\ldots n$. Then $x_1 = a_1^{-1}a_1x_1 = b_2x_2 + \cdots + b_nx_n$ and hence $\{\, x_2, \ldots, x_n \,\} \vdash x_1$. As $\{\, x_2, \ldots, x_n \,\} \subseteq X \setminus \{\, x_1 \,\}$ this yields $X \setminus \{\, x_1 \,\} \vdash x_1$, that is X is $\vdash$dependent, a contradiction. Thus there are no such x_i and a_i and this again means, that X is S-linearly indepenendent.

(iv) As $\langle B \rangle = \mathrm{Lh}_S(B)$ S-generation and $\vdash$-generation are equivalent notions. And in (ii) we have seen that $\vdash$dependence and S-linear dependence are eqivalent, too. In particular we find (a) $\Longleftrightarrow$ (b) according to the respective definitions of S-bases and $\vdash$bases. And the equivalences (a) $\Longleftrightarrow$ (c) $\Longleftrightarrow$ (d) have already been proved in (3.57.(ix)). Finally the we have already shown (b) $\Longleftrightarrow$ (e) in (3.61.(vi)).

(iii) This is just a reformulation of (3.57.(v)) in the light of (ii). Likewise (v) resp. (vi) is just the content of (3.57.(vii)) resp. (3.57.(xi)) using the equivalences (a) $\Longleftrightarrow$ (b) of (iv). Finally (vii) and (viii) are

repetitions of (3.57.(xii)) and (3.57.(xiii)) respectively. All we did was bringing the definition of the dimension into play.

(ix) If $P \leq_{\mathfrak{m}} M$ then (according to (v)) we may pick up a basis B of P. Then by assumption $|B| = \dim(P) = \dim(V)$ and M is finitely generated. Now by (viii) we find that B even is an S-basis of M, as $|B| = \dim(M)$. In particular that is $P = \mathrm{Lh}(B) = M$.

□

Proof of (3.62):

(i) Say $B = \{ m_j \mid j \in J \}$ for some index set J and let $I \subseteq J$ be the index set, such that we then get $A = \{ m_i \mid i \in I \}$. Let us first prove, that $B/P := \{ m_j + P \mid j \in J \setminus I \}$ generates M/P. To do this consider any $x \in M$, then

$$x \;=\; \sum_{j \in J} x_j m_j$$

If we take this modulo $P = \mathrm{Lh}_R \{ m_i \mid i \in I \}$, then all the m_i for some $i \in I$ are eliminated, as $m_i + P = 0 + P$. Thus the sum breaks down to

$$x + P \;=\; \sum_{j \in J} x_j (m_j + P) \;=\; \sum_{j \in J \setminus I} x_j (m_j + P)$$

So we have found some coefficients $x_j \in R$ such that $x + P$ can be written as a linear combination over the $m_j + P$ where $j \in J \setminus I$. Now it remains to prove the linear independence: Consider any $b_j \in R$ (where $j \in J \setminus I$) such that only finitely many b_j are non-zero and assume

$$\sum_{j \in J \setminus I} b_j m_j + P \;=\; \sum_{j \in J \setminus I} b_j (m_j + P) \;=\; 0 + P$$

By definition of the quotient M/P that is $\sum_j b_j m_j \in P$ and as P is generated by A we find some $a_i \in R$ (where $i \in I$) such that only finitely many a_i are non-zero and

$$\sum_{j \in J \setminus I} b_j m_j \;=\; \sum_{i \in I} a_i m_i$$

That is $\sum_i a_i m_i + \sum_j (-b_j) m_j = 0$. But this would be a linear relation between the elements m_j (where $j \in J$) of B. But as B is a basis and hence linearly independent, this implies $a_i = 0$ for any $i \in I$ and $-b_j = 0$ for any $j \in J \setminus I$. In particular this also is the linear independence of the set $B/P := \{ m_j + P \mid j \in J \setminus I \}$.

(ii) We use the same notation $B = \{ m_j \mid j \in J \}$ and $A = \{ m_i \in i \in I \}$ as in (i), before. Let us also denote the set $A' = \{ m'_k \mid k \in I' \}$. We first prove, that $B' := (B \setminus A) \cup A'$ generates M: Consider any $x \in M$, as B generates M, there are finite subsets $I_0 \subseteq I$ and $J_0 \subseteq J \setminus I$ such that

$$x \;=\; \sum_{i \in I_0} a_i m_i + \sum_{j \in J_0} b_j m_j$$

for some a_i, $b_j \in R$. By assumption we have $m_i \in \mathrm{Lh}_R(A) = P = \mathrm{Lh}_R(A')$ such that any m_i is a

linear combination of the m'_i that is any m_i can be written in the form

$$m_i \;=\; \sum_{k\in I'} a_{i,k} m'_k$$

where of course $a_{i,k} \in R$ again and only finitely many $a_{i,k}$ are non-zero. Let us insert these equations into the equation for x and use general distributivity, to find

$$x \;=\; \sum_{k\in I'} \left(\sum_{i\in I_0} a_i a_{i,k} \right) m'_k + \sum_{j\in J_0} b_j m_j$$

That is we see, that x can be expressed as an R-linear combination over the elements m'_k (where $k \in I'$) and m_j where $j \in J_0 \subseteq J \setminus I$. As these elements belong to B' and x was arbitrary we have $\mathrm{Lh}_R(B') = M$, that is B' truly generates M. It remains to prove the R-linear independence of B': Consider a linear relation of the form

$$\sum_{j\in J\setminus I} b_j m_j + \sum_{i\in I'} a'_i m'_i \;=\; 0$$

As $P = \mathrm{Lh}_R(A) = \mathrm{Lh}_R(A')$ we turn to the quotient module M/P. Again, as for any $i \in I'$ we have $m'_i \in P$, too. Hence all the m'_i are eliminated $m'_i + P = 0 + P$ such that the sum breaks down to

$$\sum_{j\in J\setminus I} b_j m_j + \sum_{i\in I'} a'_i m'_i + P \;=\; \sum_{j\in J\setminus I} b_j \big(m_j + P\big) \;=\; 0 + P$$

But in (i) we have seen, that B/P is a basis of M/P and hence we conclude $b_j = 0$ for any $j \in J \setminus I$. Therefore in the sum above we are only left with $\sum_i a'_i m'_i = 0$. But A' was assumed to be linearly independent, too, such that we conclude $a'_i = 0$. Altogether the only linear combination of elements of B' that turns up 0 has to start with all 0 coefficients. And this is the linear independence of B'.

□

Proof of (3.63):
The direction(b) $\implies$ (a) is trivial: If $X \subseteq E^{\oplus I}$ is E-linearly independent, then for any finite subset $\{ x_1, x_2, \ldots, x_n \} \subseteq X$ and any $e_i = a_i/b_i \in E$ for which we have a relation of the form

$$e_1 x_1 + e_2 x_2 + \cdots + e_n x_n \;=\; 0$$

we necessarily hav $e_1 = e_2 = \cdots = e_n = 0$. In particular this is the case for any $e_i = a_i/1 \in R$ such that $X \subseteq R^{\oplus I}$ is R-linearly independent, as well.

Conversely for (a) $\implies$ (b): Let us again consider any $\{ x_1, x_2, \ldots, x_n \} \subseteq X$ and pick up some $a_i/b_i = e_i \in E$. That is a_i and $b_i \in R$ such that $b_i \neq 0$. Let us define (for any $j \in 1 \ldots n$)

$$b \;:=\; \prod_{i=1}^{n} b_i \quad \text{and} \quad \widehat{b}_j \;:=\; \frac{b}{b_j} \;=\; \prod_{i\neq j} b_i$$

Then b and all $\widehat{b}_j \in R$ and since R is an integral domain and all the $b_i \neq 0$ are non-zero, so are $b \neq 0$

and all $\widehat{b}_j \neq 0$. Now suppose we had a dependence relation

$$e_1x_1 + e_2x_2 + \cdots + e_nx_n \;=\; 0$$

Then multiplying this equation by b we would find another relation over R

$$0 \;=\; b\left(\sum_{i=1}^{n} e_ix_i\right) \;=\; \sum_{i=1}^{n} a_i\widehat{b}_ix_i$$

Now, since $X \subseteq R^{\oplus I}$ and hence $\{\, x_1, x_2, \ldots, x_n \,\}$ is R-linearly independent, by assumption, this means $a_i\widehat{b}_i = 0$ for any $i \in 1 \ldots n$. But as $\widehat{b}_i \neq 0$ this can only be, if $a_i = 0 \in R$ and hence $e_i = a_i/b_i = 0 \in E$. Thus we see, that X then is E-linearly independent, as well. □

Proof of (3.67):
We only have to regard the following case: M is a free R-module having the basis $\mathcal{M}$. Also at least one of R or $\mathcal{M}$ is infinite. Thereby it is clear, that the cartesian product $\mathcal{M} \times R$ also is infinite. Then we have to prove the equality of

$$|M| \;=\; \max\{\, |R|, \dim(M) \,\}$$

An $\mathcal{M}$ is a basis, we have a bijective map $\mathcal{F}_0(\mathcal{M}, R) \longleftrightarrow M$, which has already been argued for in the remark. But it also is clear, that $\mathcal{F}_0(\mathcal{M}, R)$ can be embedded into the set $\Omega(\mathcal{M} \times R)$ of finite subsets of $\mathcal{M} \times R$, that is we find an injective map of the following form

$$\mathcal{F}_0(\mathcal{M}, R) \;\hookrightarrow\; \Omega(\mathcal{M} \times R) \;:\; a \;\mapsto\; \big\{\, \big(m, a(m)\big) \mid m \in \mathcal{M},\, a(m) \neq 0 \,\big\}$$

This map is injective, as we can reconstruct a from this finite subset of $\mathcal{M} \times R$, just by filling up the rest with 0. And thereby we can use property (d) of (0.38.(v)) to find the estimate

$$|M| \;=\; |\mathcal{F}_0(\mathcal{M}, R)| \;\leq\; |\Omega(\mathcal{M} \times R)| \;=\; \max\{\, |R|, |\mathcal{M}| \,\}$$

Hereby $|\mathcal{M}| = \dim(M)$, as we assumed $\mathcal{M}$ to be an R-basis of M. But the converse inequalities are clear: As $\mathcal{M} \subseteq M$ we have $|\mathcal{M}| \leq |M|$. Also, as $\mathcal{M}$ is an R-basis of M we can choose any $m \in \mathcal{M}$, this m is linearly independent and hence $R \hookrightarrow M : a \mapsto am$ is injective. But from this we also get $|R| \leq |M|$ and hence the above equality. □

Proof of (3.68):

(i) By (3.57.(vii)) and (3.64.(i)) we may choose an S-basis A of $P \cap Q$. And by the same theorems we may extend this basis to a basis B of P, that is $A \subseteq B$ and B is an S-basis of P. Likewise we pick up an S-basis C of Q, that extends A, that is $A \subseteq C$ and C is an S-basis of Q. Let us denote $D := B \cup C$ and choose any $p \in B \cap C$ then $p \in \mathrm{Lh}(B) \cap \mathrm{Lh}(C) = P \cap Q = \mathrm{Lh}(A)$. That is there are some $(s_a) \in S^{\oplus A}$ such that

$$\sum_{a \in A} s_a a \;=\; p \;=\; \sum_{b \in B} \delta_{p,b} b \;\in\; \mathrm{Lh}(B) \;=\; P$$

And as $A \subseteq B$ both sides of the equation are linear expansions of p in terms of the basis B. Due to the uniqueness of the representation this means $p = a$ (and $s_a = 1$) for some $a \in A$ and hence

$p \in A$. That is we have proved $B \cap C = A$. Therefore D is the *disjoint* union of

$$D \;=\; A \cup (B \setminus A) \cup (C \setminus A)$$

Hence the cardinality of D is the sum of the cardinalities of A, $B \setminus A$ and $C \setminus A$ respectively. And as $A \subseteq B$ and $A \subseteq C$ this turns into

$$\begin{aligned} |D| &= |A| + |B \setminus A| + |C \setminus A| \\ &= |A| + |B| - |A| + |C| - |A| \\ &= |B| + |C| - |A| \end{aligned}$$

We will now prove, that $D = B \cup C$ is an S-basis of $P + Q$. First of all it is clear that:

$$P + Q \;=\; \mathrm{ln}(B) + \mathrm{Lh}(C) \;=\; \mathrm{Lh}(B \cup C) \;=\; \mathrm{Lh}(D)$$

That is D generates $P + Q$. Now by definition it remains to prove the linear independence of D, hence: suppose we have a linear dependence equation

$$\sum_{d \in D} x_d d \;=\; 0$$

By the above D is the disjoint union of A, $B \setminus A$ and $C \setminus A$ and hence we may split this sum into three separate parts:

$$\sum_{a \in A} x_a a + \sum_{b \in B \setminus A} x_b b + \sum_{c \in C \setminus A} x_c c \;=\; 0$$

The first way to reassemble this equation is to divide it into a part contained in $P = \mathrm{Lh}(B)$ (the left-hand side) and a part contained in $Q = \mathrm{Lh}(C)$ (the right-hand side)

$$\sum_{b \in B} x_b b \;=\; -\sum_{c \in C \setminus A} x_c c$$

Conseqently both - the left- and right-hand sides - are contained in both - P and Q. Now, as $P \cap Q = \mathrm{Lh}(A)$, there are some (uniquely determined) $(y_a) \in S^{\oplus A}$ such that

$$\sum_{b \in B} x_b b \;=\; \sum_{a \in A} y_a a$$

Again we rearrange this equation, splitting it into two parts as a basis representation of 0 within $P = \mathrm{Lh}(C)$

$$\sum_{a \in A} (x_a - y_a) a + \sum_{b \in B \setminus A} x_b b \;=\; 0$$

Now, as B is linearly independent we find $x_b = 0$ for any $b \in B \setminus A$. By precisely the same arguments we can prove that $x_c = 0$ for any $c \in C \setminus A$. So there only remains $\sum_a x_a a = 0$. Again, as A is linearly independent, this means $x_a = 0$ for any $a \in A$. Altogether we have $x_d = 0$ for any $d \in D$ and this is the linear independence of D. That is D is a S-basis of $P + Q$ and therefore we

finally got

$$\begin{aligned}\dim(P+Q) &= |D| = |B|+|C|-|A| \\ &= \dim(P)+\dim(Q)+\dim(P\cap Q)\end{aligned}$$

(ii) As in (i) above, we may choose an S-basis $A \subseteq P$ of P, as S is a skew field. Again we may extend A to an S-basis $B \subseteq V$ of V. Let us now denote $B/A := \{\, b+P \mid b \in B \setminus A \,\} \subseteq V/P$. It is easy to see, that B/A corresponds to $B \setminus A$, that is $b \mapsto b+P$ is bijective. Suppose we had $b+P = c+P$ for some $b, c \in B \setminus A$. Then $c-b \in P = \mathrm{Lh}(A)$. That is either $b = c$ or $\{\, b, c \,\} \cup A \subseteq B$ is S-linearly dependent. But as B is S-linearly independent (being a basis), the latter is absurd and hence $b = c$. This is the injectivity and the surjectivity is clear from the deinition of B/A.

We now claim that B/A is an S-basis of the quotient V/P. All we need to do is check that B/A is S-linearly independent and generates V/P. For the linear independence we suppose we had some $x_b \in S$ such that

$$0 = \sum_{b+P\in B/A} x_b(b+P) = \left(\sum_{b+P\in B/A} x_b b\right) + P = \left(\sum_{b\in B\setminus A} x_b b\right) + P$$

That is $\sum_b x_b b \in P = \mathrm{Lh}(A)$ and hence there were some $x_a \in S$ such that $\sum_b x_b b = \sum_a x_a a$. Altogether that is

$$0 = \sum_{b\in B\setminus A} x_b b - \sum_{a\in A} x_a a$$

But as $B = (B \setminus A) \cup A$ is linearly independent, this can only be if all the $x_b \in S$ and all the $x_a \in S$ are identically 0. And this is what was needed for linear inependence of B/A. Also we have to check that B/A generates V/P. To do this regard any $x+P = \in V/P$. As B is a basis of V there are some $x_b \in S$ (where $b \in B$) such that $x = \sum_b x_b b$. Again we use the split $B = (B \setminus A) \cup A$ and $A \subseteq P$ to get

$$\begin{aligned}x+P &= \left(\sum_{b\in B} x_b b\right) + P = \sum_{b\in B} x_b(b+P) \\ &= \sum_{b\in B\setminus A} x_b(b+P) = \sum_{b+P\in B/A} x_b(b+P)\end{aligned}$$

As x has been arbitrary we have $V/P = \mathrm{Lh}(B/A)$ Then as B/A is a linearly independent generating set of V/P it is a basis. And therefore

$$\dim\left(V \Big/ P\right) = |B/A| = |B\setminus A| = |B|-|A| = \dim(V)-\dim(P)$$

(iii) The dimension formula now is an easy application of (ii) and the first isomorphism theorem (3.78.(ii)) which implies, that

$$V \Big/ \mathrm{kn}(\varphi) \cong_{\mathrm{m}} \mathrm{im}(\varphi)$$

In particular we have $\dim(V/\mathrm{kn}(\varphi)) = \dim(\mathrm{im}(\varphi))$. But by (ii) we now know that $\dim(V/\mathrm{kn}(\varphi)) =$

$\dim(V) - \dim(\ker(\varphi))$ such that we truly find the claim from

$$\dim(V) - \dim(\ker(\varphi)) \;=\; \dim(\operatorname{im}(\varphi))$$

□

Proof of (3.41):
We first have to prove the equality $\mathfrak{a}R^{\oplus I} = \mathfrak{a}^{\oplus I}$. The elements of $\mathfrak{a}R^{\oplus I}$ are of the form - where $a_k \in \mathfrak{a}$ and $b_k = (b_{i,k}) \in R^{\oplus I}$

$$\sum_{k=1}^{m} a_k (b_{i,k}) \;=\; \left(\sum_{k=1}^{m} a_k b_{i,k} \right) \;\in\; \mathfrak{a}^{\oplus I}$$

That is $\mathfrak{a}R^{\oplus I} \subseteq \mathfrak{a}^{\oplus I}$, conversely consider any $a = (a_i) \in \mathfrak{a}^{\oplus I}$ and let us denote the support of a by $I_0 := \{\, i \in I \mid a_i \neq 0 \,\}$. Note that (by definition of direct sums) I_0 is a finite set. Let us also denote the canonical basis of $R^{\oplus I}$ by $\{\, e_j \mid j \in I \,\}$, that is $e_j = (\delta_{i,j}) \in R^{\oplus I}$. Then we can write

$$(a_i) \;=\; \sum_{i \in I_0} a_i \, e_i \;\in\; \mathfrak{a}R^{\oplus I}$$

Altogether we have proved $\mathfrak{a}R^{\oplus I} = \mathfrak{a}^{\oplus I}$ and it remains to prove the isomorphy of $(R/\mathfrak{a})^{\oplus I}$ and $R^{\oplus I}/\mathfrak{a}R^{\oplus I}$. To do this regard the R-linear map

$$\varphi \;:\; R^{\oplus I} \to \left(R \Big/ \mathfrak{a} \right)^{\oplus I} \;:\; (b_i) \mapsto (b_i + \mathfrak{a})$$

Clearly φ is surjective, and its kernel is given to be $\ker(\varphi) = \mathfrak{a}^I \cap R^{\oplus I} = \mathfrak{a}^{\oplus I}$ such that $\ker(\varphi) = \mathfrak{a}R^{\oplus I}$. So by the first isomorphism theorem, this induces an isomorphism of R-modules

$$\Phi \;:\; R^{\oplus I} \Big/ \mathfrak{a}R^{\oplus I} \;\xrightarrow{\sim}\; \left(R \Big/ \mathfrak{a} \right)^{\oplus I} \;:\; (b_i) + \mathfrak{a}R^{\oplus I} \mapsto (b_i + \mathfrak{a})$$

But both $R^{\oplus I}/\mathfrak{a}R^{\oplus I}$ and $(R/\mathfrak{a})^{\oplus I}$ are $(R/\mathfrak{a})$-modules and from the explict construction of Φ it is clear, that Φ even is an $(R/\mathfrak{a})$-module-homomorphism. □

Proof of (2.5):

- (a) $\implies$ (c): If $\overline{\mathfrak{a}} \trianglelefteq_{\mathrm{i}} R/\mathfrak{m}$ is an ideal, then by the correspondence theorem it is of the form $\overline{\mathfrak{a}} = \mathfrak{a}/\mathfrak{m}$ for some ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{m} \subseteq \mathfrak{a}$. But as $\mathfrak{m}$ is maximal this means $\mathfrak{a} = \mathfrak{m}$ or $\mathfrak{a} = R$. Thus we have $\overline{\mathfrak{a}} = \{\, 0 + \mathfrak{m} \,\}$ (in the case $\mathfrak{a} = \mathfrak{m}$) or $\overline{\mathfrak{a}} = R/\mathfrak{m}$ (in the case $\mathfrak{a} = R$).

- (c) $\implies$ (b): $R/\mathfrak{m}$ is a non-zero (since $\mathfrak{m} \neq R$) commutative ring (since R is such). But it has already been shown that a commutative ring is a field if and only if it only contains the trivial ideals (viz. section 1.6).

- (b) $\implies$ (d): Let $a \notin \mathfrak{m}$, this means $a + \mathfrak{m} \neq 0 + \mathfrak{m}$. And as $R/\mathfrak{m}$ is a field there is some $b \in R$ such that $b + \mathfrak{m}$ is inverse to $a + \mathfrak{m}$. That is

$$ab + \mathfrak{m} \;=\; (a + \mathfrak{m})(b + \mathfrak{m}) \;=\; 1 + \mathfrak{m}$$

 Therefore there is some $m \in \mathfrak{m}$ such that $1 = ab + m \in aR + \mathfrak{m}$ and hence we have $aR + \mathfrak{m} = R$.

- (d) $\implies$ (a): Suppose $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ is some ideal with $\mathfrak{m} \subseteq \mathfrak{a}$. We want to show that $\mathfrak{m}$ is maximal hence if $\mathfrak{a} = \mathfrak{m}$ then we are done. Else there is some $a \in \mathfrak{a}$ with $a \notin \mathfrak{m}$. Hence we get $aR + \mathfrak{m} = R$. But as $a \in \mathfrak{a}$ and $\mathfrak{m} \subseteq \mathfrak{a}$ we get $R = aR + \mathfrak{m} \subseteq \mathfrak{a} \subseteq R$.

□

Proof of (2.8):

- $\neg$ (a) $\implies$ $\neg$ (b): by assumption $\neg$ (a) there is some maximal ideal $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} R$ such that $j \notin \mathfrak{m}$. Hence we have $\mathfrak{m} + jR = R$ such that is there is some $b \in R$ (let $a := -b$) such that $1 - aj = 1 + bj = 1 \in R^*$.

- $\neg$ (b) $\implies$ $\neg$ (a): by assumption $\neg$ (b) there is some $a \in R$ such that $1 - aj \notin R^*$. That is $(1 - aj)R \neq R$ is a non-full ideal and hence there is a maximal ideal $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} R$ containing it $1 - aj \in (1 - aj)R \subseteq \mathfrak{m}$ by (2.4.(ii)). If we now had $j \in \text{JAC}(R) \subseteq \mathfrak{m}$ then also $aj \in \mathfrak{m}$ and hence we would arrive at the contradiction

$$1 \;=\; (1 - aj) + aj \;\in\; \mathfrak{m}$$

- (a) $\implies$ (b): if $j \in \mathfrak{a} \subseteq \text{JAC}(R)$ then we let $a := -1$ and as we have just proved above this yields $1 + j = 1 - aj \in R^*$ and hence (b).

- (b) $\implies$ (c): first of all we have $1 \in 1 + \mathfrak{a}$ since $0 \in \mathfrak{a}$. Now consider any $a = 1 + j$ and $b = 1 + k \in 1 + \mathfrak{a}$, that is j and $k \in \mathfrak{a}$. Then $ab = 1 + (j + k + jk) \in 1 + \mathfrak{a}$ again, as $j + k + jk \in \mathfrak{a}$. Further we get

$$(1 + j)(1 - (1 + j)^{-1}j) \;=\; (1 + j) - j \;=\; 1$$

 which implies $a^{-1} = (1 + j)^{-1} = 1 - (1 + j)^{-1}j$. And hence we also have $a^{-1} \in 1 + \mathfrak{a}$, since $-(1 + j)^{-1}j \in \mathfrak{a}$ due to $j \in \mathfrak{a}$.

- (c) $\implies$ (a): fix $j \in \mathfrak{a}$ and consider any $a \in R$. Then we also get $-aj \in \mathfrak{a}$ and hence $1 - aj \in 1 + \mathfrak{a} \subseteq R^*$ by assumption. But as we have already proved above $1 - aj \in R^*$ for any $a \in R$ means $j \in \text{JAC}(R)$.

□

Proof of (2.12):

- (a) $\implies$ (b): consider $a, b \in R$ such that $0 + \mathfrak{p} = (a + \mathfrak{p})(b + \mathfrak{p}) = ab + \mathfrak{p}$. That is $ab \in \mathfrak{p}$ and as $\mathfrak{p}$ is assumed to be prime this implies $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$. This again means that $a + \mathfrak{p} = 0 + \mathfrak{p}$ or $b + \mathfrak{p} = 0 + \mathfrak{p}$ and hence $R/\mathfrak{p}$ is an integral domain. But $R/\mathfrak{p} \neq 0$ is clear, since $\mathfrak{p} \neq R$ and hence $1 + \mathfrak{p} \neq 0 + \mathfrak{p}$.

- (b) $\implies$ (c): since $R/\mathfrak{p} \neq 0$ is non-zero we have $1 + \mathfrak{p} \neq 0 + \mathfrak{p}$ or in other words $1 \notin \mathfrak{p}$ which already is (1). Now let $u, v \in R \setminus \mathfrak{p}$, then $u + \mathfrak{p} \neq 0 + \mathfrak{p}$ and $v + \mathfrak{p} \neq 0 + \mathfrak{p}$. But as $/\mathfrak{p}$ is an integral domain this then yields $uv + \mathfrak{p} = (u + \mathfrak{p})(v + \mathfrak{p}) \neq 0 + \mathfrak{p}$. Thus we also have $uv \notin \mathfrak{p}$ which is (2).

- (c) $\implies$ (a): since $1 \in R \setminus \mathfrak{p}$ we have $\mathfrak{p} \neq R$. Now consider a, $b \in R$ with $ab \in \mathfrak{p}$. Supposed we had $a \notin \mathfrak{p}$ and $b \notin \mathfrak{p}$ then a, $b \in R \setminus \mathfrak{p}$ and hence $ab \in R \setminus \mathfrak{p}$, a contradiction. Thus we truly have $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$.

- (a) $\implies$ (d): consider two ideals $\mathfrak{a}$, $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ such that $\mathfrak{ab} \subseteq \mathfrak{p}$. Suppose neither $\mathfrak{a} \subseteq \mathfrak{p}$ nor $\mathfrak{b} \subseteq \mathfrak{p}$ was true. That is there would be $a \in \mathfrak{a}$ and $b \in \mathfrak{b}$ with a, $b \notin \mathfrak{p}$. Then $ab \in \mathfrak{ab} \subseteq \mathfrak{p}$. But as $\mathfrak{p}$ has is prime this yields $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$, a contradiciton.

- (d) $\implies$ (a): consider a, $b \in R$ with $ab \in \mathfrak{p}$. Then we let $\mathfrak{a} := aR$ and $\mathfrak{b} := bR$. Then $\mathfrak{ab} = abR \subseteq \mathfrak{p}$ by (1.59), hence we find $a \in aR = \mathfrak{a} \subseteq \mathfrak{p}$ or $b \in bR = \mathfrak{b} \subseteq \mathfrak{p}$ by assumption. As we have also assumes $\mathfrak{p} \neq R$, this means that $\mathfrak{p}$ is prime.

□

Proof of (2.9):
Let $i \neq j \in 1 \dots r$, then $\mathfrak{m}_i \subseteq \mathfrak{m}_j$ would imply $\mathfrak{m}_i = \mathfrak{m}_j$ (since $\mathfrak{m}_i$ is maximal and $\mathfrak{m}_j \neq R$). Hence there is some $a_i \in \mathfrak{m}_i$ with $a_i \notin \mathfrak{m}_j$. And as we have just seen in (2.5) this means $a_i R + \mathfrak{m}_j = R$. But as $a_i \in \mathfrak{m}_i$ we find $R = a_i R + \mathfrak{m}_j \subseteq \mathfrak{m}_i + \mathfrak{m}_j \subseteq R$. Hence the $\mathfrak{m}_i$ are pairwise coprime. And the second claim follows from this, as we have proved in (1.61.(iv)).
Hence it remains to prove the third statement, i.e. the strict descent of the chain $\mathfrak{m}_1 \supset \mathfrak{m}_1\mathfrak{m}_2 \supset \dots \supset \mathfrak{m}_1 \dots \mathfrak{m}_k$. To do this we use induction on k (the foundation $k = 1$ is trivial), and let $\mathfrak{a} := \mathfrak{m}_1 \dots \mathfrak{m}_k$ and $\mathfrak{m} := \mathfrak{m}_{k+1}$. For any $i \in 1 \dots k$ there are $a_i \in \mathfrak{m}_i$ such that $a_i \notin \mathfrak{m}$ again. Now let $a := a_1 \dots a_k \in \mathfrak{a}$. Then $a \notin \mathfrak{m}$, as maximal ideals are prime (see the remark to (2.12) or (2.24) for a proof) and hence $a = a_1 \dots a_k \in \mathfrak{m}$ would imply $a_i \in \mathfrak{m}$ for some $i \in 1 \dots k$. In particular $a \notin \mathfrak{am} \subseteq \mathfrak{m}$, that is we have found the induction step

$$a \in (\mathfrak{m}_1 \dots \mathfrak{m}_k) \setminus (\mathfrak{m}_1 \dots \mathfrak{m}_k \mathfrak{m}_{k+1})$$

Finally we want to show that the powers $\mathfrak{m}_1^p$ and $\mathfrak{m}_2^q$ are coprime as well (the general case of $\mathfrak{m}_i$ and $\mathfrak{m}_j$ is just a reformulation of this). Suppose we had $\mathfrak{m}_1^p + \mathfrak{m}_2^q \neq R$, since R is a commutative ring (2.4.(ii)) tells us, that there is a maximal ideal $\mathfrak{m}$ containing $\mathfrak{m}_1^p + \mathfrak{m}_2^q$. That is we find the chain

$$\mathfrak{m}_1^p \subseteq \mathfrak{m}_1^p + \mathfrak{m}_2^q \subseteq \mathfrak{m}$$

in particular $\mathfrak{m}_1^p \subseteq \mathfrak{m}$. As any maximal ideal is prime we find $\mathfrak{m}_1 \subseteq \mathfrak{m}$ and hence $\mathfrak{m}_1 = \mathfrak{m}$, since $\mathfrak{m}_1$ is maximal, too. On the other hand, the same reasoning yields $\mathfrak{m}_2 = \mathfrak{m}$ which would contradict $\mathfrak{m}_1 \neq \mathfrak{m}_2$ being distinct ideals. This contradiction can only be resolved, it $\mathfrak{m}_1^p + \mathfrak{m}_2^q = R$. □

Proof of (2.18):

(i) Let $\mathfrak{b} := \bigcup \mathcal{P}$ be the union of all the prime ideals $\mathfrak{p} \in \mathcal{P}$. As $\mathcal{P}$ is a non-empty chain of ideals, (2.4) tells us, that $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ is an ideal again, so it remains to prove that $\mathfrak{b}$ is prime. Suppose we had $\mathfrak{b} = R$, then $1 \in \mathfrak{b}$ such that $1 \in \mathfrak{p}$ for some $\mathfrak{p} \in \mathcal{P}$. But this would mean $\mathfrak{p} = R$ in contradiction to $\mathfrak{p}$ being prime. Thus $\mathfrak{b}$ is a proper ideal. Now consider a, $b \in R$ such that $ab \in \mathfrak{b}$. That is there is some $\mathfrak{p} \in \mathcal{P}$, such that $ab \in \mathfrak{p}$. As $\mathfrak{p}$ is prime, we get $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$. As $\mathfrak{p} \subseteq \mathfrak{b}$ we get $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$, respectively. And this means that $\mathfrak{b}$ is a prime ideal, again.

(i) Let $\mathfrak{a} := \bigcap \mathcal{P}$ be the intersection of all the prime ideals $\mathfrak{p} \in \mathcal{P}$. By (1.52) this is an ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ again, so it remains to prove that $\mathfrak{a}$ is prime. To do this consider any a, $b \in R$, such that $ab \in \mathfrak{a}$.

We need to show $a \in \mathfrak{a}$ or $b \in \mathfrak{a}$ so let's assume the opposite: $a \notin \mathfrak{a}$ and $b \notin \mathfrak{a}$. That is there must be some $\mathfrak{p} \in \mathcal{P}$ such that $a \notin \mathfrak{p}$ and some $\mathfrak{q} \in \mathcal{P}$ such that $b \notin \mathfrak{q}$. Yet $ab \in \mathfrak{a} \subseteq \mathfrak{p}$ and $\mathfrak{p}$ is prime. Then we get $b \in \mathfrak{p}$, as $a \in \mathfrak{p}$ was ruled out. Likewise we conclude $a \in \mathfrak{q}$ as $ab \in \mathfrak{q}$ but $b \notin \mathfrak{q}$. Let us summarize, by now we have

$$\begin{array}{lll} a \notin \mathfrak{p} & \text{and} & b \in \mathfrak{p} \\ a \in \mathfrak{q} & \text{and} & b \notin \mathfrak{q} \end{array}$$

If $\mathcal{P}$ was not a chain, this would be the end of the story, but as $\mathcal{P}$ is totally ordered under inclusion, we can assume $\mathfrak{p} \subseteq \mathfrak{q}$ without loss of generality. Thus we have $R \setminus \mathfrak{q} \subseteq R \setminus \mathfrak{p}$. But as $b \notin \mathfrak{p}$ we have $b \in R \setminus \mathfrak{q}$ and hence $b \in R \setminus \mathfrak{p}$, as well. But this contradicts $b \in \mathfrak{p}$ and thus we must have had $a \in \mathfrak{a}$ or $b \in \mathfrak{a}$ right from the beginning.

(ii) Clearly $\mathcal{P}$ is partially ordered under the inverse inclusion relation " $\supseteq$ " (as $\mathcal{P} \neq \emptyset$). Now let $\mathcal{O} \subseteq \mathcal{P}$ be a chain in $\mathcal{P}$, then by (i) we know that $\mathfrak{p} := \bigcap \mathcal{O} \trianglelefteq_{\mathfrak{i}} R$ is prime. Now pick any $\mathfrak{q} \in \mathcal{O}$, then as $\mathfrak{p} \subseteq \mathfrak{q}$ and the assumption on $\mathcal{P}$ we find $\mathfrak{p} \in \mathcal{P}$. Hence $\mathfrak{p}$ is a $\supseteq$-upper bound of $\mathcal{O}$. And by the lemma of Zorn this yields that $\mathcal{P}$ contains a $\supseteq$-maximal element $\mathfrak{p}_*$. But clearly $\supseteq$-maximal is $\subseteq$-minimal and hence $\mathfrak{p}_* \in \mathcal{P}_*$.

(iii) Let us take $\mathcal{Z} := \{ \mathfrak{p} \in \operatorname{Spec}(R) \mid \text{condition}(\mathfrak{p}) \}$, then $\mathcal{Z}$ is partially ordered under the inverse inclusion " $\supseteq$ " of sets. In any case $\mathcal{Z} \neq \emptyset$ is non-empty: if we imposed *none* then by assumption $R \neq 0$ and hence R has a maximal (in particular prime) ideal due to (2.4.(iv)). If we imposed $\mathfrak{p} \subseteq \mathfrak{q}$ then $\mathfrak{q} \in \mathcal{Z}$. If we imposed $\mathfrak{a} \subseteq \mathfrak{p}$ then by assumption $\mathfrak{a} \neq R$ and hence there is a maximal (in particular prime) ideal $\mathfrak{m}$ containing $\mathfrak{a} \subseteq \mathfrak{m}$ due to (2.4.(ii)) again. Finally if we supposed $\mathfrak{a} \subseteq \mathfrak{p} \subseteq \mathfrak{q}$ then we assumed $\mathfrak{a} \subseteq \mathfrak{q}$ and hence $\mathfrak{q} \in \mathcal{Z}$. Now let $\mathcal{P} \subseteq \mathcal{Z}$ be any chain in $\mathcal{Z}$ and $\mathfrak{p} := \bigcap \mathcal{P}$. Then by (i) $\mathfrak{p}$ is a prime ideal of R again. Also $\mathfrak{a} \subseteq \mathfrak{p}$ and $\mathfrak{p} \subseteq \mathfrak{q}$ are clear (if they have been imposed). Hence $\mathfrak{p} \in \mathcal{Z}$ is an upper bound of $\mathcal{P}$ (under $\supseteq$). And hence there is a maximal element $\mathfrak{p}_* \in \mathcal{Z}^*$ by the lemma of Zorn. But as $\mathfrak{p}_*$ is maximal with respect to $\supseteq$ it is minimal with respect to $\subseteq$.

(iv) By assumption $\mathfrak{a} \subseteq \mathfrak{q}$ and (iii) there is some prime ideal $\mathfrak{p}_*$ minimal among the ideals $\mathfrak{p}_* \in \{ \mathfrak{p} \in \operatorname{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \subseteq \mathfrak{q} \}_*$ and in particular $\mathfrak{a} \subseteq \mathfrak{p}_* \subseteq \mathfrak{q}$. It remains to prove, that $\mathfrak{p}_*$ also is a minimal element of $\{ \mathfrak{p} \in \operatorname{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \}$. Thus suppose we are given any prime ideal $\mathfrak{p}$ with $\mathfrak{a} \subseteq \mathfrak{p}$ and $\mathfrak{p} \subseteq \mathfrak{p}_*$. Then in particular $\mathfrak{p} \subseteq \mathfrak{q}$ and by the minimality of $\mathfrak{p}_*$ this then implies $\mathfrak{p} = \mathfrak{p}_*$. Thus $\mathfrak{p}_*$ even is minimal in this larger set.

(v) Let us take $\mathcal{Z} := \{ \mathfrak{b} \trianglelefteq_{\mathfrak{i}} R \mid \mathfrak{a} \subseteq \mathfrak{b} \subseteq R \setminus U \}$, then $\mathcal{Z}$ is partially ordered under "$\subseteq$". Clearly $\mathcal{Z} \neq \emptyset$ is non-empty, since $\mathfrak{a} \in \mathbb{Z}$, as we have assumed $\mathfrak{a} \cap U = \emptyset$. Now let $\mathcal{B} \subseteq \mathcal{Z}$ be any chain in $\mathcal{Z}$, then $\mathfrak{c} := \bigcup \mathcal{B}$ is an ideal, due to (2.4). And if we pick any $\mathfrak{b} \in \mathcal{B}$ then $\mathfrak{a} \subseteq \mathfrak{b} \subseteq \mathfrak{c}$ and hence $\mathfrak{a} \subseteq \mathfrak{c}$. And if $b \in \mathfrak{c}$ then there is some $\mathfrak{b} \in \mathcal{B} \subseteq \mathcal{Z}$ such that $b \in \mathfrak{b} \subseteq R \setminus U$. Hence we also find $\mathfrak{c} \subseteq R \setminus U$ such that $\mathfrak{c} \in \mathcal{Z}$ again. That is we have found an upper bound $\mathfrak{c}$ of $\mathcal{B}$. Hence there is a maximal element $\mathfrak{b}^* \in \mathcal{Z}$ by the lemma of Zorn. Now let $\mathfrak{p} \in \mathcal{Z}^*$ be any maximal element of $\mathcal{Z}$. As $\mathfrak{p} \subseteq R \setminus U$ and $1 \in U$ we have $1 \notin \mathfrak{p}$ such that $\mathfrak{p} \neq R$ is non-full. Now consider any $a, b \in R$ such that $ab \in \mathfrak{p}$ but suppose $a \notin \mathfrak{p}$ and $b \notin \mathfrak{p}$. As we have $\mathfrak{p} \subset \mathfrak{p} + aR$ and $\mathfrak{p} \in \mathcal{Z}^*$ is maximal we have $(\mathfrak{p} + aR) \not\subseteq R \setminus U$. That is we may choose $u \in (\mathfrak{p} + aR) \cap U$. That is $u = p + \alpha a$ for some $p \in \mathfrak{p}$ and $\alpha \in R$. Analogously we can find some $v = q + \beta b \in (\mathfrak{p} + bR) \cap U$ with $q \in \mathfrak{p}$ and

$\beta \in R$. Thereby we get

$$uv \;=\; (p+\alpha a)(q+\beta b) \;=\; pq+\alpha aq+\beta bp+\alpha\beta ab \;\in\; \mathfrak{p}$$

since p, q and $ab \in \mathfrak{p}$. But as U is multiplicatively closed and u, $v \in U$ we also have $uv \in U$. That is $uv \in \mathfrak{p} \cap U$, a contradiction to $\mathfrak{p} \in \mathcal{Z}$. Hence we have $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$ which means that $\mathfrak{p}$ is prime.

□

Proof of (2.14):

(i) We will prove the statement by induction on k - the case $k = 1$ being trivial. So let now $k \geq 2$ and let $a := a_1 \ldots a_{k-1}$ and $b := a_k$. Then $ab = a_1 \ldots a_{k-1}a_k \in \mathfrak{p}$, but as $\mathfrak{p}$ is prime this implies $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$. If $b \in \mathfrak{p}$ then we are done (with $i := k$). If not then $a = a_1 \ldots a_{k-1} \in \mathfrak{p}$, so by induction hypothesis we get $a_i \in \mathfrak{p}$ for some $i \in 1 \ldots k-1$.

(ii) Analogous to (i) we prove this statement by induction on k - the case $k = 1$ being trivial again. For $k \geq 2$ we likewise let $\mathfrak{a} := \mathfrak{a}_1 \ldots \mathfrak{a}_{k-1}$ and $\mathfrak{b} := \mathfrak{a}_k$. Then $\mathfrak{ab} \subseteq \mathfrak{p}$ implies $\mathfrak{a} \subseteq \mathfrak{p}$ or $\mathfrak{b} \subseteq \mathfrak{p}$ due to (2.12). If $\mathfrak{b} \subseteq \mathfrak{p}$ then we are done with $i := k$. Else $\mathfrak{a} \subseteq \mathfrak{p}$ and hence $\mathfrak{a}_i \subseteq \mathfrak{p}$ for some $i \in 1 \ldots k-1$ by induction hypothesis.

(iii) Let us choose a subset $I \subseteq 1 \ldots n$ such that $\mathfrak{a}$ is contained in the union of the $\mathfrak{b}_i$ ($i \in I$) with a minimal number of elements. That is

$$\mathfrak{a} \;\subseteq\; \bigcup_{i \in I} \mathfrak{b}_i$$

$$\forall\, J \subseteq 1 \ldots n \;:\; \mathfrak{a} \subseteq \bigcup_{i \in J} \mathfrak{b}_i \implies \#I \leq \#J$$

It is clear that this can be done, since $J = 1 \ldots n$ suffices to cover $\mathfrak{a}$ and the number of elements is a total order and hence allows to pick a minimal element. In the following we will prove that I contains precisely one element. And in this case $I = \{\, i \,\}$ we clearly have $\mathfrak{a} \subseteq \mathfrak{b}_i$ as claimed. Thus let us assume $\#I \geq 2$ and derive a contradiction: consider some fixed $j \in I$, as I has minimally many elements we have

$$\mathfrak{a} \;\not\subseteq\; \bigcup_{j \neq i \in I} \mathfrak{b}_i$$

That is there is some $a_j \in \mathfrak{a}$ such that $a_j \notin \mathfrak{b}_i$ for any $j \neq i \in I$. In particular we find $a_j \in \mathfrak{b}_j$, as the $\mathfrak{b}_i$ ($i \in I$) cover $\mathfrak{a}$. Let us pick one such a_j for every $j \in I$. If $\#I = 2$ then we may assume $I = \{\, 1, 2 \,\}$ without loss of generality. As a_1 and $a_2 \in \mathfrak{a}$ we also have $a_1 + a_2 \in \mathfrak{a}$. Suppose we had $a_1 + a_2 \in \mathfrak{b}_1$ then $a_2 = (a_1 + a_2) + (-a_1) \in \mathfrak{b}_1$ as well, a contradiction. Likewise we find that $a_1 + a_2 \notin \mathfrak{b}_2$. But now $a_1 + a_2 \in \mathfrak{a} \subseteq \mathfrak{b}_1 \cup \mathfrak{b}_2$ provides a contradiction. Hence $\#I = 2$ cannot be. Now assume $\#I \geq 3$, then by assumption there is some $k \in I$ such that $\mathfrak{b}_k$ is prime. Without loss of generality (that is by renumbering) we may assume $I = 1 \ldots m$ and $\mathfrak{b}_1$ to be prime. As any $a_i \in \mathfrak{a}$ we also have $a_1 + a_2 \ldots a_m \in \mathfrak{a}$. Suppose $a_1 + a_2 \ldots a_m \in \mathfrak{b}_i$ for some $i \in 2 \ldots m$, then $a_1 = (a_1 + a_2 \ldots a_m) + (-a_2 \ldots a_m) \in \mathfrak{b}_i$ too, a contradiction. And if we suppose $a_1 + a_2 \ldots a_m \in \mathfrak{b}_1$ then $a_2 \ldots a_m = (a_1 + a_2 \ldots a_m) + (-a_1) \in \mathfrak{b}_1$ too. As $\mathfrak{b}_1$ is prime we find $a_i \in \mathfrak{b}_1$ for some $i \in 2 \ldots m$ due to (i). But this is a contradiction, altogether $a_1 + a_2 \ldots a_m$ is

contained in $\mathfrak{a}$ but none of the $\mathfrak{b}_i$ for $i \in I$, a contradiction. Hence the assumption $\#I \geq 3$ has to be abandoned, which only leaves $\#I = 1$.

(iv) For the implication (a) $\implies$ (b) we first note that by definition of the minimal spectrum we have $\mathrm{Smin}R \subseteq \mathrm{Spec}(R)$ and by assumption also $\mathrm{Spec}(R) = \mathrm{Smax}(R)$ such that $\mathrm{Smin}(R) \subseteq \mathrm{Smax}(R)$. For the converse inclusion we regard any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$. In particular $\mathfrak{m}$ is prime, now take $\mathfrak{a} = 0$ to impose no restrictions in (2.18.(iv)) to produce a minimal ideal $\mathfrak{p}_* \in \mathrm{Smin}(R)$ such that $\mathfrak{p}_* \subseteq \mathfrak{m}$. In particular $\mathfrak{p}_*$ is prime and hence maximal by assumption. But now $\mathfrak{p}_* \subseteq \mathfrak{m} \neq R$ implies $\mathfrak{p}_* = \mathfrak{m}$, such that $\mathfrak{m}$ is a minimal prime ideal of R. Therefore $\mathrm{Smax}(R) \subseteq \mathrm{Smin}(R)$, as well.

For the implication (b) $\implies$ (a) we only have to show $\mathrm{Spec}(R) \subseteq \mathrm{Smax}(R)$. That is we begin with any $\mathfrak{p} \in \mathrm{Spec}(R)$. Again take $\mathfrak{a} = 0$ and use (2.18.(iv)) to find a minimal prime ideal $\mathfrak{p}_* \in \mathrm{Smin}(R)$ such that $\mathfrak{p}_* \subseteq \mathfrak{p}$. By assumption $\mathfrak{p}_*$ is maximal, such that $\mathfrak{p}_* = \mathfrak{p}$. In particular $\mathfrak{p} = \mathfrak{p}_* \in \mathrm{Smin}(R) = \mathrm{Smax}(R)$ is a maximal ideal.

And by definition of the Krull-dimension we have $\mathrm{kdim}(R) = 0$ if and only if any chain of prime ideals has length 1. That is any $\mathfrak{p} \in \mathrm{Spec}(R)$ admits no distinct prime ideals below or above it. And this is precisely the case if $\mathfrak{p}$ is both: maximal and minimal. Hence $\mathrm{kdim}(R) = 0$ is just a reformulation of property (b) in other words.

□

Proof of (2.10):
As the maximal ideals $\mathfrak{m}_i$ are distinct, we know by (2.9) that $\mathfrak{m}_i + \mathfrak{m}_j = R$ are coprime. Hence we may employ the Chinese remainder theorem (1.99.(iii)) to get the isomorphism

$$R \Big/ \mathfrak{j} \;\cong_{\mathrm{r}}\; \bigoplus_{i=1}^{r} R \Big/ \mathfrak{m}_i \;:\; a + \mathfrak{j} \mapsto \Big(a + \mathfrak{m}_i\Big)$$

Now consider any prime ideal $\overline{\mathfrak{p}} \trianglelefteq_{\mathrm{i}} R/\mathfrak{j}$, then by the correspondence theorem of ideals (1.66) $\overline{\mathfrak{p}}$ is of the form $\overline{\mathfrak{p}} = \mathfrak{p}/\mathfrak{j}$ for some prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ of R, with $\mathfrak{j} \subseteq \mathfrak{p}$. However by (2.9) we also know that $\mathfrak{j}$ is the product $\mathfrak{j} = \mathfrak{m}_1 \cdot \mathfrak{m}_2 \cdot \dots \cdot \mathfrak{m}_r$ of these maximal ideals. And as $\mathfrak{p}$ is prime $\mathfrak{m}_1 \dots \mathfrak{m}_r \subseteq \mathfrak{p}$ implies $\mathfrak{m}_i \subseteq \mathfrak{p}$ for some $i \in 1 \dots r$ - this is (2.14.(ii)). But as $\mathfrak{m}_i$ is maximal, $\mathfrak{m}_i \subseteq \mathfrak{p} \neq R$ implies $\mathfrak{m}_i = \mathfrak{p}$ and hence $\overline{\mathfrak{p}} = \mathfrak{m}_i/\mathfrak{j}$. In particular any prime ideal $\overline{\mathfrak{p}}$ already is a maximal ideal. □

Proof of (2.16):
As any ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ contains $0 \in \mathfrak{p}$ we have $0 \subseteq \mathfrak{p}$ such that $\mathbb{V}(0) = \mathrm{Spec}(R)$. And as any prime ideal $\mathfrak{p} \in \mathrm{Spec}(R)$ is proper $\mathfrak{p} \neq R$ we *never* have $R \subseteq \mathfrak{p}$. That is $\mathbb{V}(R) = \emptyset$. We will now prove

$$\mathbb{V}\left(\sum_{i \in I} \mathfrak{a}_i\right) \;=\; \bigcap_{i \in I} \mathbb{V}(\mathfrak{a}_i)$$

Clearly if $\sum_i \mathfrak{a}_i \subseteq \mathfrak{p}$ then $\mathfrak{a}_i \subseteq \mathfrak{p}$ for any $i \in I$ and hence $\mathfrak{p} \in \mathbb{V}(\mathfrak{a}_i)$ for any $i \in I$. Conversely let $\mathfrak{a}_i \subseteq \mathfrak{p}$ for any $i \in I$. If $b \in \mathfrak{b} := \sum_i \mathfrak{a}_i$ then there is a finite subset $\Omega \subseteq I$ and $a_i \in \mathfrak{a}_i$ (where $i \in \Omega$) such that $b = \sum_i a_i$ (where the sum runs over $i \in \Omega$). In particular $a_i \in \mathfrak{a}_i \subseteq \mathfrak{p}$ and hence $b \in \mathfrak{p}$ such

that $\mathfrak{b} \subseteq \mathfrak{p}$ which in turn is $\mathfrak{p} \in \mathbb{V}(\mathfrak{b})$. It remains to prove

$$\mathbb{V}\left(\bigcap_{i=1}^{n} \mathfrak{a}_i\right) \;=\; \bigcup_{i=1}^{n} \mathbb{V}(\mathfrak{a}_i)$$

If $\bigcap_i \mathfrak{a}_i \subseteq \mathfrak{p}$ then - as $\mathfrak{p}$ is prime and we know (2.14.(ii)) - then there is some $j \in 1 \ldots n$ such that $\mathfrak{a}_j \subseteq \mathfrak{p}$. But this again means $\mathfrak{p} \in \mathbb{V}(\mathfrak{a}_j)$ for some $j \in 1 \ldots n$. Conversely if $\mathfrak{p} \in \mathbb{V}(\mathfrak{a}_j)$ for some $j \in 1 \ldots n$ then $\bigcap_i \mathfrak{a}_i \subseteq \mathfrak{a}_j \subseteq \mathfrak{p}$ such that $\mathfrak{p} \in \mathbb{V}(\bigcap_i \mathfrak{a}_i)$ is granted.

It remains to prove $\mathbb{V}(abR) = \mathbb{V}(aR) \cup \mathbb{V}(bR)$: As $ab \in aR$ we have $abR \subseteq aR$ and from this it is clear, that $\mathbb{V}(aR) \subseteq \mathbb{V}(abR)$. As the same is true for $\mathbb{V}(bR) \subseteq \mathbb{V}(abR)$ we have the inclusion $\mathbb{V}(aR) \cup \mathbb{V}(bR) \subseteq \mathbb{V}(abR)$. For the converse inclusion we regard any $\mathfrak{p} \in \mathbb{V}(abR)$, that is $ab \in abR \subseteq \mathfrak{p}$. As $\mathfrak{p}$ is a prime ideal and $ab \in \mathfrak{p}$ we conclude $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$. In case $a \in \mathfrak{p}$ we have $aR \subseteq \mathfrak{p}$, which is $\mathfrak{p} \in \mathbb{V}(aR)$. Likewise we conclude $\mathfrak{p} \in \mathbb{V}(bR)$ from $b \in \mathfrak{p}$. In any case we have $\mathfrak{p} \in \mathbb{V}(aR) \cup \mathbb{V}(bR)$ and as this is true for any $\mathfrak{p} \in \mathbb{V}(abR)$, this means $\mathbb{V}(abR) \subseteq \mathbb{V}(aR) \cup \mathbb{V}(bR)$, too. □

Proof of (2.17):

- We will first show the well-definedness of $\mathrm{Spec}(\varphi)$ - it is clear that $\varphi^{-1}(\mathfrak{q}) = \{\, a \in R \mid \varphi(a) \in \mathfrak{q} \,\}$ is an ideal in R. Thus it only remains to show that $\varphi^{-1}(\mathfrak{q}) \in X$ truly is prime. First of all $\varphi^{-1}(\mathfrak{q}) \neq R$ as else $1 \in \varphi^{-1}(\mathfrak{q})$ and this would mean $1 = \varphi(1) \in \mathfrak{q}$. But this is absurd, as $\mathfrak{q}$ is prime and hence $\mathfrak{q} \neq S$. Hence we consider $ab \in \varphi^{-1}(\mathfrak{q})$, i.e. $\varphi(ab) = \varphi(a)\varphi(b) \in \mathfrak{q}$. As $\mathfrak{q} \in Y$ is prime, this yields $\varphi(a) \in \mathfrak{q}$ or $\varphi(b) \in \mathfrak{q}$, that is $a \in \varphi^{-1}(\mathfrak{q})$ or $b \in \varphi^{-1}(\mathfrak{q})$ again.

- Next we will show that for any $a \in R$ we have $(\mathrm{Spec}\varphi)^{-1}(X_a) = Y_{\varphi(a)}$. But this is immediate from elementary set theory, since

$$(\mathrm{Spec}(\varphi))^{-1}(X_a) \;=\; \left\{\, \mathfrak{q} \in Y \mid a \notin \varphi^{-1}(\mathfrak{q}) \,\right\} \;=\; Y_{\varphi(a)}$$

- Likewise $(\mathrm{Spec}(\varphi))(\mathbb{V}(\mathfrak{b})) \subseteq \mathbb{V}(\varphi^{-1}(\mathfrak{b}))$ is completely obvious, once we translate these sets back into set-theory, then we have to show

$$\left\{\, \varphi^{-1}(\mathfrak{q}) \mid \mathfrak{b} \subseteq \mathfrak{q} \in Y \,\right\} \;\subseteq\; \left\{\, \mathfrak{p} \in X \mid \varphi^{-1}(\mathfrak{b}) \subseteq \mathfrak{p} \,\right\}$$

 Thus we have to show that $\mathfrak{b} \subseteq \mathfrak{q} \in Y$ implies $\varphi^{-1}(\mathfrak{b}) \subseteq \varphi^{-1}(\mathfrak{q}) \in X$. But $\mathfrak{b} \subseteq \mathfrak{q}$ clearly implies $\varphi^{-1}(\mathfrak{b}) \subseteq \varphi^{-1}(\mathfrak{q})$ and we have just proved, that $\varphi^{-1}(\mathfrak{q}) \in X$ as well.

- Finally it remains to prove $(\mathrm{Spec}(\varphi))^{-1}(\mathbb{V}(\mathfrak{a})) = \mathbb{V}(\langle \varphi(\mathfrak{a}) \rangle_i)$. So let us first translate the claim back into elementary set-theory again

$$\left\{\, \mathfrak{q} \in Y \mid \mathfrak{a} \subseteq \varphi^{-1}(\mathfrak{q}) \,\right\} \;=\; \{\, \mathfrak{q} \in Y \mid \varphi(\mathfrak{a}) \subseteq \mathfrak{q} \,\}$$

 But by definition we have $\varphi^{-1}(\mathfrak{q}) = \{\, a \in R \mid \varphi(a) \in \mathfrak{q} \,\}$, and hence the inclusion $\mathfrak{a} \subseteq \varphi^{-1}(\mathfrak{q})$ trivially implies $\varphi(\mathfrak{a}) \subseteq \mathfrak{q}$ and vice versa.

□

Proof of (2.22):

(i) First of all $\mathfrak{a} \subseteq \mathfrak{a} : b$, because if $a \in \mathfrak{a}$ then also $ab \in \mathfrak{a}$, as $\mathfrak{a}$ is an ideal. Next we will prove that $\mathfrak{a} : b \trianglelefteq_{\mathrm{i}} R$ is an ideal of R. It is clear that $0 \in \mathfrak{a} : b$ since $0b = 0 \in \mathfrak{a}$. Let now p and $q \in \mathfrak{a} : b$, that is pb and $qb \in \mathfrak{a}$. Then $(p+q)b = pb + qb \in \mathfrak{a}$, $(-p)b = (-pb) \in \mathfrak{a}$ and for any $a \in R$ we also get $(ap)b = a(pb) \in \mathfrak{a}$ which means $p+q$, $-p$ and $ap \in \mathfrak{a} : b$ respectively.

(ii) First of all $\mathfrak{a} \subseteq \sqrt{\mathfrak{a}}$, because if $a \in \mathfrak{a}$ then for $k = 1$ we get $a^k = a \in \mathfrak{a}$. Next we will prove that $\sqrt{\mathfrak{a}} \trianglelefteq_{\mathrm{i}} R$ is an ideal. It is clear that $0 \in \mathfrak{a} \subseteq \sqrt{\mathfrak{a}}$. Now let a and $b \in \sqrt{\mathfrak{a}}$ that is $a^k \in \mathfrak{a}$ and $b^l \in \mathfrak{a}$ for some $k, l \in \mathbb{N}$. Then we get

$$\begin{aligned}
(-a)^k &= (-1)^k a^k \\
(ab)^l &= a^l b^l \\
(a+b)^{k+l} &= \sum_{i=0}^{k+l} \binom{k+l}{i} a^i b^{k+l-i} \\
&= \sum_{i=0}^{k} \binom{k+l}{i} a^i b^{k+l-i} + \sum_{i=k+1}^{k+l} \binom{k+l}{i} a^i b^{k+l-i} \\
&= \sum_{i=0}^{k} \binom{k+l}{i} a^i b^{k+l-i} + \sum_{j=1}^{l} \binom{k+l}{k+j} a^{k+j} b^{l-j} \\
&= \left(\sum_{i=0}^{k} \binom{k+l}{i} a^i b^{k-i} \right) b^l + \left(\sum_{j=1}^{l} \binom{k+l}{k+j} a^j b^{l-j} \right) a^k
\end{aligned}$$

As all these elements are contained in $\mathfrak{a}$ again, we again found $a+b$, $-a$ and $ab \in \sqrt{\mathfrak{a}}$. Thus it remains to prove that $\sqrt{\mathfrak{a}}$ is a radical ideal. Thus let $a \in R$ be contained in the radical of $\sqrt{\mathfrak{a}}$, that is $a^k \in \sqrt{\mathfrak{a}}$ for some $k \in \mathbb{N}$. And hence there is some $l \in \mathbb{N}$ such that $a^{kl} = (a^k)^l \in \mathfrak{a}$. But this already means $a \in \sqrt{\mathfrak{a}}$ and the converse inclusion is clear.

(iii) If $a \in \mathfrak{a} : b$ then $ab \in \mathfrak{a} \subseteq \mathfrak{b}$ and hence $a \in \mathfrak{b} : b$ again. Likewise if we are given $a \in \sqrt{\mathfrak{a}}$ then there is some $k \in \mathbb{N}$ such that $a^k \in \mathfrak{a} \subseteq \mathfrak{b}$ and hence $a \in \sqrt{\mathfrak{b}}$ already.

(iv) If $1 \in R = \mathfrak{a} : b$ then $b = 1b \in \mathfrak{a}$. And if $b \in \mathfrak{a}$ then for any $a \in R$ we have $ab \in \mathfrak{a}$, since $\mathfrak{a}$ is an ideal. But this also means $\mathfrak{a} : b = R$. Now let $\mathfrak{p}$ be a prime ideal of R, if $b \in \mathfrak{p}$ then we have alredy seen $\mathfrak{p} : b = R$. Thus assume $b \notin \mathfrak{p}$. Then $a \in \mathfrak{p} : b$ is equivalent to $ab \in \mathfrak{p}$ for any $a \in R$. But as $\mathfrak{p}$ is prime this implies $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$. The latter is untrue by assumption so we get $a \in \mathfrak{p}$. That is we have proved $\mathfrak{p} : b \subseteq \mathfrak{p}$ and the converse inclusion has been proved in (i) generally.

(v) If $\emptyset \neq \mathcal{A} \subseteq \operatorname{Srad}(R) \subseteq \operatorname{Ideal}(R)$, then the intersection $\bigcap \mathcal{A} \trianglelefteq_{\mathrm{i}} R$ already is an ideal of R due to (1.52). Thus it remains to show that $\bigcap \mathcal{A}$ is radical. Let $a^k \in \bigcap \mathcal{A}$, that is $a^k \in \mathfrak{a}$ for any $\mathfrak{a} \in \mathcal{A}$. But as $\mathfrak{a}$ is radical we find that $a \in \mathfrak{a}$. As this is true for any $\mathfrak{a} \in \mathcal{A}$ we found $a \in \bigcap \mathcal{A}$.

(v) Consider any $a \in R$, then a is contained in the intersection of all $\mathfrak{a}_i : \mathfrak{b}$ iff $a \in \mathfrak{a}_i : b$ for any $i \in I$. And this again is equivalent to $ab \in \mathfrak{a}_i$ for any $i \in I$. Thus we have already found the equivalence

$$a \in \bigcap_{i \in I} (\mathfrak{a}_i : b) \iff ab \in \bigcap_{i \in I} \mathfrak{a}_i \iff a \in \left(\bigcap_{i \in I} \mathfrak{a}_i \right) : b$$

□

Proof of (2.23):
(c) $\iff$ (a) is trivial and so is (a) $\implies$ (b). For the converse implication it suffices to remark, that $\mathfrak{a} \subseteq \sqrt{\mathfrak{a}}$ is true for any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ (as $a \in \mathfrak{a}$ implies $a = a^1 \in \mathfrak{a}$). Thus we prove (a) $\implies$ (d): Let $b + \mathfrak{a}$ be a nilpotent of $R/\mathfrak{a}$, that is $b^k + \mathfrak{a} = (b + \mathfrak{a})^k = 0 + \mathfrak{a}$ for some $k \in \mathbb{N}$. This means $b^k \in \mathfrak{a}$ and hence $b \in \sqrt{\mathfrak{a}} \subseteq \mathfrak{a}$ by assumption. And from $b \in \mathfrak{a}$ we find $b + \mathfrak{a} = 0 + \mathfrak{a}$. Conversely (d) $\implies$ (c): consider any $b \in R$ such that $b^k \in \mathfrak{a}$. Then $(b + \mathfrak{a})^k = b^k + \mathfrak{a} = 0 + \mathfrak{a}$ and hence $b + \mathfrak{a}$ is a nilpotent of $R/\mathfrak{a}$. By assumption this means $b + \mathfrak{a} = 0 + \mathfrak{a}$ or in other words $b \in \mathfrak{a}$. □

Proof of (2.24):
The equivalences of the respecive properties of the ideal and its quotient ring have been shown in (2.5), (2.12) and (2.23) respectively. Hence if $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ is maximal then $R/\mathfrak{m}$ is a field. In particular $R/\mathfrak{m}$ is a non-zero integral domain which means that $\mathfrak{m}$ is prime. And if $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ is prime, then $R/\mathfrak{p}$ is an integral domain and hence reduced which again means that $\mathfrak{p}$ is a radical ideal. Yet we also wish to present a direct proof of this:

- $\mathfrak{m}$ maximal $\implies$ $\mathfrak{m}$ prime: consider $a, b \in \mathfrak{m}$ with $ab \in \mathfrak{m}$, but suppose $a \notin \mathfrak{m}$ and $b \notin \mathfrak{m}$. This means $\mathfrak{m} \subset \mathfrak{m} + aR$ and hence $\mathfrak{m} + aR = R$, as $\mathfrak{m}$ is maximal. Hence there are $m \in \mathfrak{m}$ and $\alpha \in R$ such that $m + \alpha a = 1$. Likewise there are $n \in \mathfrak{m}$ and $\beta \in R$ such that $n + \beta b = 1$. Thereby

$$1 \;=\; (m + \alpha a)(n + \beta b) \;=\; mn + \alpha an + \beta bm + \alpha\beta ab$$

 But as m, n and $ab \in \mathfrak{m}$ we hence found $1 \in \mathfrak{m}$ which means $\mathfrak{m} = R$. But this contradicts $\mathfrak{m}$ being maximal.

- $\mathfrak{p}$ prime $\implies$ $\mathfrak{p}$ radical: consider $a \in R$ with $a^k \in \mathfrak{p}$. As $\mathfrak{p}$ is prime we have $k \geq 0$ (as else $1 = a^0 \in \mathfrak{p}$ such that $\mathfrak{p} = R$). But $\mathfrak{p}$ is prime and hence $a^k \in \mathfrak{p}$ for some $k \geq 1$ implies $a \in \mathfrak{p}$ due to (2.14.(i)). This means that $\mathfrak{p}$ is radical, due to (2.23.(c)).

□

Proof of (2.25):

(i) As $\mathfrak{a} \neq R$ is proper, there is a maximal ideal containing $\mathfrak{a}$ and maximal ideals are prime. Hence $\mathbb{V}(\mathfrak{a}) = \{\, \mathfrak{p} \mid \mathfrak{a} \subseteq \mathfrak{p} \,\}$ is non-empty, such that the intersection is well-defined. We have to prove $\sqrt{\mathfrak{a}} = \bigcap \mathbb{V}(\mathfrak{a})$. Thereby the inclusion "$\subseteq$" is clear, as any $\mathfrak{p}$ that contains $\mathfrak{a}$ also contains $\sqrt{\mathfrak{a}}$. For the converse inclusion we are given some $a \in R$ such that $a \in \mathfrak{p}$ for any prime ideal $\mathfrak{p} \in \mathbb{V}(\mathfrak{a})$. Now let $U := \{\, 1, a, a^2 \ldots \}$, then it is clear that U is multiplicatively closed. Suppose $\mathfrak{a} \cap U = \emptyset$, then by (2.18.(iv)) there was an ideal $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ maximal with $\mathfrak{a} \subseteq \mathfrak{b} \subseteq R \setminus U$. And this ideal $\mathfrak{b}$ was prime. But as $\mathfrak{b} \cap U = \emptyset$ and $a \in U$ we have $a \notin \mathfrak{b}$ even though $\mathfrak{b} \in \mathbb{V}(\mathfrak{a})$, a contradiction. Thus we have $\mathfrak{a} \cap U \neq \emptyset$, that is there is some $b \in U$ such that $b \in \mathfrak{a}$. By construction of U b is of the form $b = a^k$ for some $k \in \mathbb{N}$. And this means $a \in \sqrt{\mathfrak{a}}$.

(i) Let us denote $\mathbb{V}(\mathfrak{a}) := \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\}$ again and $\mathcal{M} := \mathbb{V}(\mathfrak{a})_*$. Then in (i) above we have just seen the identity

$$\sqrt{\mathfrak{a}} \;=\; \bigcap \mathbb{V}(\mathfrak{a})$$

We now have to prove $\bigcap \mathbb{V}(\mathfrak{a}) = \bigcap \mathcal{M}$. As $\mathcal{M} \subseteq \mathbb{V}(\mathfrak{a})$ the inclusion "$\subseteq$" is clear. For the converse inclusion we are given any $a \in \bigcap \mathcal{M}$ and any $\mathfrak{q} \in \mathbb{V}(\mathfrak{a})$ and need to show $a \in \mathfrak{q}$. But as $\mathfrak{a} \subseteq \mathfrak{q}$

by (i) there is some $\mathfrak{p}_* \in \mathcal{M}$ such that $\mathfrak{a} \subseteq \mathfrak{p}_* \subseteq \mathfrak{p}$. And as $a \in \bigcap \mathcal{M}$ we find $a \in \mathfrak{p}_*$ and hence $a \in \mathfrak{q}$. Thus we have also established inclusion " $\supseteq$ ".

(ii) By definition it is clear that $\text{NIL}(R) = \sqrt{0}$ is the radical of the zero-ideal. And the further equalities given are immediate from (ii) above.

(iii) Let $a \in R$ be contained in the radical of $\sqrt{\mathfrak{a}}$, that is $a^k \in \sqrt{\mathfrak{a}}$ for some $k \in \mathbb{N}$. And hence there is some $l \in \mathbb{N}$ such that $a^{kl} = (a^k)^l \in \mathfrak{a}$. But this already means $a \in \sqrt{\mathfrak{a}}$ and the converse inclusion is clear.

(v) As $\mathfrak{a}\,\mathfrak{b} \subseteq \mathfrak{a} \cap \mathfrak{b}$ we have $\sqrt{\mathfrak{a}\,\mathfrak{b}} \subseteq \sqrt{\mathfrak{a} \cap \mathfrak{b}}$ by (i). Next let $a \in \sqrt{\mathfrak{a} \cap \mathfrak{b}}$, that is there is some $k \in \mathbb{N}$ such that $a^k \in \mathfrak{a} \cap \mathfrak{b}$. Now $a^k \in \mathfrak{a}$ and $a^k \in \mathfrak{b}$ implies $a \in \sqrt{\mathfrak{a}} \cap \sqrt{\mathfrak{b}}$. Finally consider some $a \in \sqrt{\mathfrak{a}} \cap \sqrt{\mathfrak{b}}$, that is $a^i \in \mathfrak{a}$ and $a^j \in \mathfrak{b}$ for some $i, j \in \mathbb{N}$. Then $a^{i+j} = a^i a^j \in \mathfrak{a}\,\mathfrak{b}$ and hence $a \in \sqrt{\mathfrak{a}\,\mathfrak{b}}$. Altogether we have proved the following chain of inclusions

$$\sqrt{\mathfrak{a}\,\mathfrak{b}} \;\subseteq\; \sqrt{\mathfrak{a} \cap \mathfrak{b}} \;\subseteq\; \sqrt{\mathfrak{a}} \cap \sqrt{\mathfrak{b}} \;\subseteq\; \sqrt{\mathfrak{a}\,\mathfrak{b}}$$

(vi) By induction on (v) we know that $\sqrt{\mathfrak{a}^n} = \sqrt{\mathfrak{a}} \cap \cdots \cap \sqrt{\mathfrak{a}}$ (n-times). And this obviously equals $\sqrt{\mathfrak{a}}$ such that we get the equality $\sqrt{\mathfrak{a}^n} = \sqrt{\mathfrak{a}}$ claimed. And if $\mathfrak{a}$ is a radical ideal, to begin with, then $\sqrt{\mathfrak{a}^k} = \sqrt{\mathfrak{a}} = \mathfrak{a}$ again.

(iv) In a first step let us assume $k = 1$, that is $\mathfrak{a} \subseteq \mathfrak{p} \subseteq \sqrt{\mathfrak{a}}$, then in particular we have $\mathfrak{a} \subseteq \mathfrak{p}$ and hence $\sqrt{\mathfrak{a}} \subseteq \sqrt{\mathfrak{p}}$. Yet as $\mathfrak{p}$ is prime we also have $\sqrt{\mathfrak{p}} = \mathfrak{p}$ due to (2.24). Thereby we get $\sqrt{\mathfrak{a}} \subseteq \mathfrak{p} \subseteq \sqrt{\mathfrak{a}}$ by assumption. Now consider an arbitrary $k \in \mathbb{N}$. Then by (vi) we have $\mathfrak{a}^k \subseteq \mathfrak{p} \subseteq \sqrt{\mathfrak{a}} = \sqrt{\mathfrak{a}^k}$. Thus by the case $k = 1$ (using $\mathfrak{a}^k$ instead of $\mathfrak{a}$) we get $\mathfrak{p} = \sqrt{\mathfrak{a}^k} = \sqrt{\mathfrak{a}}$, the latter by (vi) again.

(vii) By assumption $\mathfrak{a}$ is finitely generated, that is there are $a_i \in R$ such that $\mathfrak{a} = \langle a_1, \ldots, a_n \rangle_{\text{i}}$. And as $\mathfrak{a}$ is contained in the radical of $\mathfrak{b}$ we find that for any $i \in 1 \ldots n$ there is some $k(i) \in \mathbb{N}$ such that $a_i^{k(i)} \in \mathfrak{b}$. Now let $k := k(1) + \cdots + k(n)$ and consider $f_1, \ldots, f_k \in \mathfrak{a}$. That is

$$f_j \;=\; \sum_{i=1}^{n} f_{i,j} a_i$$

for some $f_{i,j} \in R$. Using (1.41) we now extract the product of the f_j

$$\prod_{j=1}^{k} f_j \;=\; \prod_{j=1}^{k} \sum_{i=1}^{n} f_{i,j} a_i \;=\; \sum_{i \in I} \prod_{j=1}^{k} f_{i_j,j} a_{i_j}$$

where $I = (1 \ldots n)^k$ and $i = (i_1, \ldots, i_k) \in I$. For any $h \in 1 \ldots n$ we now let $m(h) := \#\left\{ j \in 1 \ldots k \mid i_j = h \right\}$ the number of times h appears in the collection of i_j. Then it is clear that $m(1) + \cdots + m(n) = k = k(1) + \cdots + k(n)$ Hence there has to be some index $h \in 1 \ldots n$ such that $k(h) \leq m(h)$. Thereby $a_h^{m(h)}$ divides $a_h^{k(h)} \in \mathfrak{b}$ such that

$$b_i \;:=\; \prod_{j=1}^{k} a_{i_j} \;=\; \prod_{h=1}^{n} a_h^{m(h)} \;\in\; \mathfrak{b}$$

This now can be used to show $f_1 \dots f_k \in \mathfrak{b}$. Simply rearrange to find

$$\prod_{j=1}^{k} f_j \;=\; \sum_{i\in I}\prod_{j=1}^{k} f_{i_j,j}a_{i_j} \;=\; \sum_{i\in I}\left(\prod_{j=1}^{k} f_{i_j,j}\right) b_i \;\in\; \mathfrak{b}$$

Now recall that - by definition - $\mathfrak{a}^k$ consists precisely of sums of elements of the form $f_1 \dots f_k$ where $f_j \in \mathfrak{a}$. As we have seen any such element is contained in $\mathfrak{b}$ and hence $\mathfrak{a}^k \subseteq \mathfrak{b}$.

(viii) If a is contained in the radical of the intersection of the $\mathfrak{a}_i$ then there is some $k \in \mathbb{N}$ such that a is contained in the intersection of the $\mathfrak{a}_i$. That is $a^k \in \mathfrak{a}_i$ for any $i \in I$ and hence $a \in \sqrt{\mathfrak{a}_i}$ for any $i \in I$.

(viii) Let a be contained in the sum of the radicals $\sqrt{\mathfrak{a}_i}$. That is a is a finite sum of the form $a = a_1 + + \dots a_n$ where a_j is contained in the radical of $\mathfrak{a}_{i(j)}$. Thereby for any $j \in 1 \dots n$ we get

$$a_j \in \sqrt{\mathfrak{a}_{i(j)}} \quad\Longrightarrow\quad \exists\, k(j) \in \mathbb{N} \;:\; a_j^{k(j)} \in \mathfrak{a}_{i(j)}$$

Now let $k := k(1) + \dots + k(n) \in \mathbb{N}$, then by the polynomial rule (1.41)

$$a^k \;=\; \sum_{|\alpha|=k}\prod_{j=1}^{n} a_j^{\alpha(j)}$$

Suppose that for any $j \in 1 \dots n$ we had $\alpha(j) = k(j)$, then $|\alpha| = \alpha(1) + \dots + \alpha(n) < k(1) + \dots + k(n) = k$, a contradiction. Hence there is some $j \in 1 \dots n$ such that $k(j) \leq \alpha(j)$. And for this j we have $a_j^{\alpha(j)} \in \mathfrak{a}_{i(j)}$. Thus a^k is contained in the radical of $\mathfrak{a}_{i(1)} + \dots + \mathfrak{a}_{i(n)}$ and in particular in the radical of the sum of all $\mathfrak{a}_i$.

□

Proof of (2.28):
Fix any commutative ring $(E, +, \cdot)$ and consider the polynomial ring $S := E[t_i \mid 1 \leq i \in \mathbb{N}]$ in countable infinitely many variables over E. Then we take to the quotient where for any $1 \leq i \in \mathbb{N}$ we have $t_i^i = 0$. Formally

$$R \;:=\; {}^{S}\!\Big/_{\mathfrak{v}} \quad\text{where}\quad \mathfrak{v} \;:=\; \langle t_i^i \mid 1 \leq i \in \mathbb{N}\rangle_{\mathfrak{i}}$$

For any $f \in S$ let us denote its residue class in R by $\overline{f} := f + \mathfrak{v}$. And further let us define the *size* of f to be the maximum index i such that t_i appears among the variable symbols of f. Formally that is

$$\mathrm{size}(f) \;:=\; \max\{\, 1 \leq i \in \mathbb{N} \mid \exists\, \alpha : f[\alpha] \neq 0,\ \alpha_i \neq 0 \,\}$$

Note that this truly is finite, as there only are finitely many α such that $f[\alpha] \neq 0$ and for any $\alpha = (\alpha_i)$ there also are finitely many i only, such that $\alpha_i \neq 0$. As our exemplary ideal let us take the zero-ideal $\mathfrak{a} := 0$. By construction we have $(\bar{t}_i)^i = 0$ and hence $\bar{t}_i \in \sqrt{0}$. On the other hand we have (for any $n \in \mathbb{N}$ with $n < i$)

$$(\bar{t}_i)^n \;\in\; (\sqrt{0})^n \quad\text{but}\quad (\bar{t}_i)^n \neq 0$$

Thus for any $n \in \mathbb{N}$ let us just take some $i \in \mathbb{N}$ with $n < i$. Then $\bar{t}_i$ demonstrates that $(\sqrt{0})^n$ is not contained in 0. Also $\sqrt{0}$ is not finitely generated. Because if we consider a finite collection of elements

$\overline{f}_1,\ldots,\overline{f}_k \in \sqrt{0}$ then just take $i > \max\{\,\mathrm{size}(f_j) \mid j \in 1\ldots k\,\}$. Then it is clear that $f_j \in E[t_1,\ldots,t_{i-1}]$ and hence $t_i \notin \langle f_1,\ldots,f_k\rangle_{\mathfrak{i}}$. And thereby

$$\bar{t}_i \;\notin\; \langle f_1,\ldots,f_k\rangle_{\mathfrak{i}} \Big/ \mathfrak{v} \;=\; \langle \overline{f}_1,\ldots,\overline{f}_k\rangle_{\mathfrak{i}}$$

□

Proof of (2.31):

(i) Consider any $a \in R$, then $a \in \sqrt{\mathfrak{b}} \cap R$ is equivalent, to $\varphi(a) \in \sqrt{\mathfrak{b}}$. That is iff there is some $k \in \mathbb{N}$ such that $\varphi(a^k) = \varphi(a)^k \in \mathfrak{b}$. This again is $a^k \in \mathfrak{b} \cap R$, which is equivalent to $a \in \sqrt{\mathfrak{b} \cap R}$.

(ii) In order to prove $\sqrt{\mathfrak{a}}S \subseteq \sqrt{\mathfrak{a}S}$ we have to verify $\varphi(\sqrt{\mathfrak{a}}) \subseteq \sqrt{\mathfrak{a}S}$. Thus consider any $a \in \sqrt{\mathfrak{a}}$, that is $a^k \in \mathfrak{a}$ for some $k \in \mathbb{N}$. But from this we get $\varphi(a)^k = \varphi(a^k) \in \varphi(\mathfrak{a}) \subseteq \mathfrak{a}S$. And this again is $\varphi(a) \in \sqrt{\mathfrak{a}S}$, which had to be shown. Next, as $\mathfrak{a} \subseteq \sqrt{\mathfrak{a}}$ we clearly have $\mathfrak{a}S \subseteq \sqrt{\mathfrak{a}}S$ which gives rise to the incusion

$$\sqrt{\mathfrak{a}S} \;\subseteq\; \sqrt{\sqrt{\mathfrak{a}}S}$$

Conversely consider any $f \in S$ such that $f^k \in \sqrt{\mathfrak{a}}\,S$ for some $k \in \mathbb{N}$. That is there are $g_i \in S$ and $a_i \in \sqrt{\mathfrak{a}}$ such that

$$f^k \;=\; g_1\varphi(a_1) + \cdots + g_n\varphi(a_n)$$

As a_i is contained in $\sqrt{\mathfrak{a}}$ there is some $k(i) \in \mathbb{N}$ such that $a_i^{k(i)} \in \mathfrak{a}$. Now let us abbreviate $b_i := \varphi(a_i)$, $l := k(1) + \cdots + k(n)$ and $m := k \cdot l$. Then we get

$$f^m \;=\; (g_1b_1 + \ldots g_nb_n)^l \;=\; \sum_{|\alpha|=l} \binom{l}{\alpha} (g_1b_1)^{\alpha(1)} \ldots (g_nb_n)^{\alpha(n)}$$

Now fix any α and suppose for any $i \in 1\ldots n$ we had $\alpha(i) < k(i)$, then we had $l = |\alpha| = \alpha(1) + \cdots + \alpha(n) < k(1) + \cdots + k(n) = l$ an obvious contradiction. Hence for any α there is some $j \in 1\ldots n$ such that $\alpha(j) \geq k(j)$. And for this j we get

$$b_j^{\alpha(j)} \;=\; b_j^{\alpha(j)-k(j)} b_j^{k(j)} \;=\; b_j^{\alpha(j)-k(j)} \varphi\left(a_j^{k(j)}\right) \;\in\; \mathfrak{a}\,S$$

But as this holds true for any α with $|\alpha| = l$ we find that $f^m \in \mathfrak{a}\,S$. And this again means that f is contained in the radical of $\mathfrak{a}\,S$.

(iii) The equivalence $\mathfrak{b}$ is a $\star$ iff $\varphi^{-1}(\mathfrak{b})$ is a $\star$ has already been proved in the correspondence theorem (1.66). Thus from now on φ is surjective, then $\varphi(\mathfrak{a})$ is a ideal of S due to (1.76). Now compute

$$\begin{aligned}
\varphi^{-1}\varphi(\mathfrak{a}) &= \{\, b \in R \mid \varphi(b) \in \varphi(\mathfrak{a}) \,\} \\
&= \{\, b \in R \mid \exists\, a \in \mathfrak{a} : \varphi(b) = \varphi(a) \,\} \\
&= \{\, b \in R \mid \exists\, a \in \mathfrak{a} : b - a \in \mathrm{kn}(\varphi) \,\} \\
&= \{\, b \in R \mid \exists\, a \in \mathfrak{a} : b \in a + \mathrm{kn}(\varphi) \,\} \\
&= \{\, a + \mathrm{kn}(\varphi) \mid a \in \mathfrak{a} \,\} \\
&= \mathfrak{a} + \mathrm{kn}(\varphi)
\end{aligned}$$

Now by the first claim $\mathfrak{b} := \varphi(\mathfrak{a})$ is a $\star$ iff $\varphi^{-1}(\mathfrak{b}) = \varphi^{-1}\varphi(\mathfrak{a}) = \mathfrak{a} + \mathrm{kn}(\varphi)$ is a $\star$. And this already is the second claim.

□

Proof of (2.33):

- The equivalence of (a) and (b): The implication (b) $\implies$ (a) is trivial: Let us abbreviate $\mathbb{V}^*(\mathfrak{a}) := \{\, \mathfrak{m} \in \mathrm{Smax}(R) \mid \mathfrak{a} \subseteq \mathfrak{m} \,\}$ then we can take this set to be $\mathcal{M}$. Thereby $\mathbb{V}^*(\mathfrak{a})$ is non-empty, as $\mathfrak{a}$ is proper and we have (2.4.(ii)). Now to (a) $\implies$ (b): Consider any $\mathfrak{m} \in \mathcal{M}$, as $\mathfrak{a} \subseteq \sqrt{\mathfrak{a}} = \bigcap \mathcal{M} \subseteq \mathfrak{m}$ we find that $\mathcal{M} \subseteq \mathbb{V}^*(\mathfrak{a})$ and thereby

$$\bigcap \mathbb{V}^*(\mathfrak{a}) \quad \subseteq \quad \bigcap \mathcal{M} \quad = \quad \sqrt{\mathfrak{a}}$$

 Conversely, if $\mathfrak{m}$ is a maximal ideal containing $\mathfrak{a} \subseteq \mathfrak{m}$, then $\sqrt{\mathfrak{a}} \subseteq \sqrt{\mathfrak{m}} = \mathfrak{m}$, as any maximal ideal is prime and any prime ideal is radical. And as this is true for any $\mathfrak{m} \in \mathbb{V}^*(\mathfrak{a})$ we also find

$$\sqrt{\mathfrak{a}} \quad \subseteq \quad \bigcap \mathbb{V}^*(\mathfrak{a})$$

- The equivalence of (b) and (c): As any prime ideal is radical it satisfies $\sqrt{\mathfrak{p}} = \mathfrak{p}$ such that he implication (b) $\implies$ (c) is satisfied trivially. Conversely consider any proper ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$, for this - by (2.25.(i)) - we already know

$$\sqrt{\mathfrak{a}} \quad = \quad \bigcap \mathbb{V}(\mathfrak{a}) \quad = \quad \bigcap \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\}$$

 By assumption (c) any $\mathfrak{p}$ is the intersection of all maximal ideals of R containing $\mathfrak{p}$. Let us rewrite all this in a little more intuitive way

$$\sqrt{\mathfrak{a}} \quad = \quad \bigcap_{\mathfrak{a} \subseteq \mathfrak{p}} \mathfrak{p} \quad = \quad \bigcap_{\mathfrak{a} \subseteq \mathfrak{p}} \bigcap \{\, \mathfrak{m} \in \mathrm{Smax}(R) \mid \mathfrak{p} \subseteq \mathfrak{m} \,\} \quad = \quad \bigcap_{\mathfrak{a} \subseteq \mathfrak{p}\, \mathfrak{p} \subseteq \mathfrak{m}} \mathfrak{m}$$

 That is $\sqrt{\mathfrak{a}}$ is the intersection of all maximal ideals $\mathfrak{m}$ for which there is a prime ideal $\mathfrak{p}$ such that $\mathfrak{a} \subseteq \mathfrak{p}$ and $\mathfrak{p} \subseteq \mathfrak{m}$. We now claim that this amounts to

$$\sqrt{\mathfrak{a}} \quad = \quad \bigcap_{\mathfrak{a} \subseteq \mathfrak{p}\, \mathfrak{p} \subseteq \mathfrak{m}} \mathfrak{m} \quad = \quad \bigcap \{\, \mathfrak{m} \in \mathrm{Smax}(R) \mid \mathfrak{a} \subseteq \mathfrak{m} \,\}$$

 If there is some $\mathfrak{p} \in \mathrm{Spec}(R)$ such that $\mathfrak{a} \subseteq \mathfrak{p}$ and $\mathfrak{p} \subseteq \mathfrak{m}$, then $\mathfrak{a} \subseteq \mathfrak{m}$, as well. If conversely $\mathfrak{a} \subseteq \mathfrak{m}$, then we may just take $\mathfrak{p} := \mathfrak{m}$, as any maximal ideal also is prime. Thus the intersection runs over precisely the same set of maximal ideals $\mathfrak{m}$ and hence is equal.

- The equivalence of (c) and (e) is an immediate consequence of the correspondence theorem of ideals. Recall our abbreviation $\mathbb{V}^*(\mathfrak{p}) := \{\, \mathfrak{m} \in \mathrm{Smax}(R) \mid \mathfrak{p} \subseteq \mathfrak{m} \,\}$ then we evaluate the Jacobson-radical of $R/\mathfrak{a}$, using the correspondence (1.71)

$$\mathrm{JAC}\left(R/\mathfrak{p}\right) \quad = \quad \bigcap \mathrm{Smax}\left(R/\mathfrak{p}\right) \quad = \quad \bigcap \left\{ \mathfrak{m}/\mathfrak{p} \;\middle|\; \mathfrak{m} \in \mathbb{V}^*(\mathfrak{p}) \right\}$$

 The correspondence theorem (1.66.(ii)) also tells us that the intersection of ideals is compatible,

that is we can interchange intersection and quotient to arrive at

$$\textsc{jac}\left(R\big/\mathfrak{p}\right) \;=\; \bigcap \mathbb{V}^*(\mathfrak{p})\big/\mathfrak{p}$$

If (c) then $\bigcap \mathbb{V}^*(\mathfrak{p}) = \mathfrak{p}$ such that we find $\textsc{jac}(R/\mathfrak{p}) = \mathfrak{p}/\mathfrak{p} = 0$, which is (e). Conversely if (e), then by the correspondence of ideals we have $\bigcap \mathbb{V}^*(\mathfrak{p}) = \mathfrak{p}$, which is (c). Hence the equivalence.

- The equivalence of (b) and (d) is another consequence of the correspondence theorem of ideals. Let us evaluate also the nil-radical of $R/\mathfrak{a}$, using (1.71) again, we find

$$\textsc{nil}\left(R\big/\mathfrak{a}\right) \;=\; \bigcap \textsf{Spec}\left(R\big/\mathfrak{a}\right) \;=\; \bigcap \left\{ \mathfrak{p}\big/\mathfrak{a} \;\middle|\; \mathfrak{p} \in \mathbb{V}(\mathfrak{a}) \right\}$$

As before we can interchange intersection and quotient according to (1.66.(ii)), but this time we can also use (2.25.(i)), which is $\bigcap \mathbb{V}(\mathfrak{a}) = \sqrt{\mathfrak{a}}$, to arrive at

$$\textsc{nil}\left(R\big/\mathfrak{a}\right) \;=\; \bigcap \mathbb{V}(\mathfrak{a})\big/\mathfrak{a} \;=\; \sqrt{\mathfrak{a}}\big/\mathfrak{a}$$

We have already evaluated the Jacobson-radical of $R/\mathfrak{a}$ in the previous step (for this we did not use that $\mathfrak{p}$ was a prime ideal). So let us recollect the result

$$\textsc{jac}\left(R\big/\mathfrak{a}\right) \;=\; \bigcap \textsf{Smax}\left(R\big/\mathfrak{a}\right) \;=\; \bigcap \mathbb{V}^*(\mathfrak{a})\big/\mathfrak{a}$$

Now if (b), then we have $\sqrt{\mathfrak{a}} = \bigcap \mathbb{V}^*(\mathfrak{a})$ such that the nil- and Jacobson-radicals of $R/\mathfrak{a}$ coincide, which is (d). Conversely if (d), then by the correspondence of ideals we have $\sqrt{\mathfrak{a}} = \bigcap \mathbb{V}^*(\mathfrak{p})$, which is (b). Hence the equivalence.

- The equivalence of (e) and (f): Here (f) $\implies$ (e) is obvious: If $\mathfrak{p}$ is a prime ideal, then $S := R/\mathfrak{p}$ is an integral domain and $\varrho : R \to R/\mathfrak{p} : a \mapsto a + \mathfrak{p}$ is surjective. Hence we get $\textsc{jac}(R/\mathfrak{p}) = 0$ by (f). Conversely let $\mathfrak{p} := \textsf{kn}(\varphi)$, then by the first isomorphism theorem (1.83.(ii)) we obtain an isomorphism between $R/\mathfrak{p}$ and S by virtue of

$$\widetilde{\varphi} \;:\; R\big/\mathfrak{p} \;\xrightarrow{\sim}\; S \;:\; a + \mathfrak{p} \mapsto \varphi(a)$$

As S is an integral domain, so is $R/\mathfrak{p}$ and this means that $\mathfrak{p}$ is a prime ideal. Thus by (e) we have $\textsc{jac}(R/\mathfrak{p}) = 0$. But as $\widetilde{\varphi}$ is an isomorphism we thereby get

$$\begin{aligned} \textsc{jac}(S) \;&=\; \bigcap \{\, \mathfrak{n} \mid \mathfrak{n} \in \textsf{Smax}(S) \,\} \;=\; \bigcap \{\, \widetilde{\varphi}(\mathfrak{m}) \mid \mathfrak{m} \in \textsf{Smax}(R/\mathfrak{a}) \,\} \\ &=\; \widetilde{\varphi}\left(\bigcap \{\, \mathfrak{m} \mid \mathfrak{m} \in \textsf{Smax}(R/\mathfrak{a}) \,\} \right) \;=\; \widetilde{\varphi}\left(\textsc{jac}(R/\mathfrak{p})\right) \;=\; 0 \end{aligned}$$

□

Proof of (3.106):

- We will first prove the implication (a) $\implies$ (b): that is we regard a non-empty family $\mathcal{P} \subseteq \textsf{Subm}(M)$ of sumbodules of M. We will give a proof by contradiction, that is we suppose $\mathcal{P}$ had *no* maximal element. That is for any $P \in \mathcal{P}$ there is some $Q \in \mathcal{P}$ with $P \subseteq Q$ but $P \neq Q$. As $\mathcal{P}$ is non-empty we can start with some $P_0 \in \mathcal{P}$. Suppose we have already found $P_0 \subset P_1 \subset \ldots \subset P_k$ where

$P_i \in \mathcal{P}$. As $\mathcal{P}$ has no maximal elements P_k is not maximal, that is $P_k \subset P_{k+1}$ for some $P_{k+1} \in \mathcal{P}$. Continuing indefinitely we would find a non-stationary chain $P_0 \subset P_1 \subset \ldots \subset P_k \subset P_{k+1} \subset \ldots$ in contradiction to (a).

- Next let us prove (b) $\Longrightarrow$ (c): that is we are given any sub-module $Q \leq_{\mathsf{m}} M$ of M. To do this let us regard the set of finitly generated sub-modules of Q

$$\mathcal{P} \;:=\; \{\, P \leq_{\mathsf{m}} Q \mid P \text{ finitely generated} \,\}$$

Clearly $0 \in \mathcal{P}$, such that $\mathcal{P}$ is non-empty. By assumption (b) contains a maximal element $P^* \in \mathcal{P}$. Now for any $x \in Q$ it is clear that $P := P^* + \mathsf{Lh}(x)$ is another finitely generated sub-module of Q [clearly if $P^* = \mathsf{Lh}(x_1, \ldots, x_n)$ then $P = \mathsf{Lh}(x_1, \ldots, x_n, x)$]. That is $P \in \mathcal{P}$ again and $P^* \subseteq P$. By maximality of P^* this is $P^* = P$ and hence $x \in P = P^*$. As $x \in Q$ has been chosen arbitarily this means $Q \subseteq P^*$ and hence $Q = P^*$. In particular $Q \in \mathcal{P}$ is finitely generated itself.

- Let us first close the circle by proving (c) $\Longrightarrow$ (a): that is we regard some ascending chain $P_0 \subseteq P_1 \subseteq P_2 \subseteq \ldots$ of sub-modules $P_k \leq_{\mathsf{m}} M$ of M. As the P_k for a chain we know by (3.27.(v)) that the union

$$P \;:=\; \bigcup_{k \in \mathbb{N}} P_k \quad \leq_{\mathsf{m}} \quad M$$

is a sub-module of M again. And by assumption (c) it is finitely generated, that is $P = \mathsf{Lh}(x_1, \ldots, x_r)$ for some $x_i \in P$. That is for any $i \in 1 \ldots r$ there is some $k(i) \in \mathbb{N}$ such that $x_i \in P_{k(i)}$ now take $s := \max\{\, i(1), \ldots, i(r) \,\} \in \mathbb{N}$. Then - as the P_k for an ascending chain - we have $x_i \in P_{k(i)} \subseteq P_s$ again. In particular $P = \mathsf{Lh}(x_1, \ldots, x_r) \subseteq P_s$ such that for any $j \in \mathbb{N}$ we have $P \subseteq P_s \subseteq P_{s+j} \subseteq P$ which implies $P_{s+j} = P_s$. This means that the chain (P_k) becomes stationary at the index s, which proves (a).

□

Proof of (3.111):

(i) If M is $\star$ then P clearly is $\star$ as well, as any chain of sub-modules of P also is a chain of sub-modules of M. Also M/P is $\star$ again: by the corrspondence theorem (3.16.(ii)) any sub-module of M/P is of the form Q/P for some sub-module $Q \leq_{\mathsf{m}} M$. Hence any chain of sub-modules of M/P corresponds to a chain of sub-modules in M and hence stabilizes.

Conversely suppose both P and M/P are noetherian, then we have to prove that M is noetherian. To do this we regard an ascending chain of sub-modules

$$Q_0 \;\subseteq\; Q_1 \;\subseteq\; \ldots \subseteq\; Q_k \;\subseteq\; Q_{k+1} \;\subseteq\; \ldots$$

Then $Q_0 \cap P \subseteq Q_1 \cap P \subseteq Q_2 \cap P \subseteq \ldots$ is an ascending chain of sub-modules. As P is noetherian it stabilizes, that is there is some $r \in \mathbb{N}$ such that for any $i \in \mathbb{N}$ we have $Q_{r+i} \cap P = Q_r \cap P$. Also we obtain an ascending chain of sub-modules of M/P by

$$Q_0 + P \,\big/_P \;\subseteq\; Q_1 + P \,\big/_P \;\subseteq\; Q_2 + P \,\big/_P \;\subseteq\; \ldots$$

As M/P is noetherian as well this chain stabilizes, too, that is there is some $t \in \mathbb{N}$ such that for all $i \in \mathbb{N}$ we have $(Q_{t+i} + P)/P = (Q_t + P)/P$. By the correspondense theorem this already is $Q_{t+i} + P = Q_t + P$. Now choose $s := \max(r, t)$, then for any $i \in \mathbb{N}$ we have

$$Q_{s+i} \cap P \;=\; Q_s \cap P \quad \text{and} \quad Q_{s+i} + P \;=\; Q_s + P$$

Now by the modular rule (3.17) this implies $Q_{s+i} = Q_s$ which means that M is noetherian, as well.

In case that both P and M/P are artinian, we regard a descending chain $Q_0 \supseteq Q_1 \supseteq Q_2 \supseteq \ldots$ and use the same arguments as above to show that it stabilizes, as well. All we have to do is replace any "$\subseteq$" by "$\supseteq$".

(iv) Clearly M is isomorphic to the sub-module $M \oplus 0$ of $M \oplus N$ by virtue of $M \xrightarrow{\sim} M \oplus 0 : x \mapsto (x, 0)$. Also it is clear that N is isomorphic to the quotient $(M \oplus N)/(M \oplus 0)$ under the isomorhism

$$N \;\xrightarrow{\sim}\; M \oplus N \Big/ {}_{M \oplus 0} \;:\; y \mapsto (0, y) + (M \oplus 0)$$

Thus regarding $M \oplus 0$ as a sub-module of $M \oplus N$ we know that $M \oplus N$ is $\star$ if and only if both $M \oplus 0$ and $(M \oplus N)/(M \oplus 0)$ are $\star$. But due to the isomorphisms this again is equivalent to both M and N being $\star$.

(ii) It is really easy to see, that $M/(P \cap Q)$ can be embedded into $(M/P) \oplus (M/Q)$ by virtue of the following map

$$M \Big/ {}_{P \cap Q} \hookrightarrow M \Big/ {}_{P} \oplus M \Big/ {}_{Q} \;:\; x + (P \cap Q) \mapsto (x + P, x + Q)$$

Because, if $x + P = y + P$ and $x + Q = y + Q$ then we have both $x - y \in P$ and $x - y \in Q$. And this means $x - y \in P \cap Q$ which yields $x + (P \cap Q) = y + (P \cap Q)$. Hence the above map is injective. As both M/P and M/Q are $\star$ so is $(M/P) \oplus (M/Q)$ according to (iv). But as $M/(P \cap Q)$ is isomorphic to a sub-module of $(M/P) \oplus (M/Q)$ and this isomorphic copy is $\star$ according to (i), so is $M/(P \cap Q)$.

(v) As $\varphi : M \twoheadrightarrow N$ is surjective, the first isomorphism theorem (3.78.(ii)) yields an isomorphism $M/\mathrm{kn}(\varphi) \xrightarrow{\sim} N$ by virtue of $x + \mathrm{kn}(\varphi) \mapsto \varphi(x)$. In particular N is isomprphic to a quotient module $M/\mathrm{kn}(\varphi)$ of M. Now, as M is $\star$, we find that $M/\mathrm{kn}(\varphi)$ is $\star$ due to (i) and hence N is $\star$ because of the isomorphy.

(iii) As P and Q are $\star$ by (iv) we know that $P \oplus Q$ is $\star$. But clearly there is a surjective R-module homomorphism $P \oplus Q \twoheadrightarrow P + Q$ by letting $(x, y) \mapsto x + y$. The surjectivity is trivial and the R-linearity is obvious: $a(x, y) = (ax, ay) \mapsto ax + ay = a(x + y)$ and $(u, v) + (x, y) = (u + x, v + y) \mapsto (u + x) + (v + y) = (u + v) + (x + y)$. Hence by (v) we find that $P + Q$ is $\star$ again, as it is an epimorphic image of $P \oplus Q$.

(vi) Since M is finitely generated we can choose some generators $x_k \in M$, that is $M = \mathrm{Lh}(x_1, \ldots, x_n)$. Then we clearly have an R-module epimorphism by letting

$$R^n \twoheadrightarrow M \;:\; (a_1, \ldots, a_n) \mapsto \sum_{i=k}^{n} a_k x_k$$

As R is $\star$ as a ring it also is $\star$ as an R-module (in fact this even is equivalent). Using (iv) and induction on n it is clear that $R^n = R \oplus R \oplus \cdots \oplus R$ (n-times) is $\star$ again. Hence M is $\star$, by (v), as it is an epimorphic image of a $\star$ module.

(vii) Let us denote the R-module homomorphisms by $\varphi : L \hookrightarrow M$ and $\psi : M \twoheadrightarrow N$, that is we regard the following exact chain

$$0 \to L \xrightarrow{\varphi} M \xrightarrow{\psi} N \to 0$$

As ψ is injective we find that $\mathrm{kn}(\psi) = \mathrm{im}(\varphi)$ is isomorphic to L under $L \to \mathrm{kn}(\psi) : x \mapsto \varphi(x)$. And as ψ is surjective, by the first isomorphism theorem (3.78.(ii)), we also get the isomorphism

$$M \Big/ \mathrm{kn}(\psi) \xrightarrow{\sim} N \ : \ y + \mathrm{kn}(\psi) \mapsto \psi(y)$$

By (i) we know, that M is $\star$ if and only if both $\mathrm{kn}(\psi)$ and $M/\mathrm{kn}(\psi)$ are $\star$. And due to the above isomorphisms, this now is equivalent to both L and N being $\star$.

□

Proof of (3.110):

- Suppose $P \subseteq \mathbb{Q}$ is a finitely generated $\mathbb{Z}$-sub-module of $\mathbb{Q}$. That is there are some $x_k = a_k/b_k$ (where $k \in 1 \dots n$) that generate P, then we let $b := b_1 b_2 \dots b_n$ and $\widehat{b_k} := b/b_k \in \mathbb{Z}$. Then any element of P is of the form

$$\sum_{k=1}^{n} r_k \frac{a_k}{b_k} \ = \ \sum_{k=1}^{n} \frac{r_k a_k \widehat{b_k}}{b} \ = \ \left(\sum_{k=1}^{n} r_k a_k \widehat{b_k} \right) \frac{1}{b} \ \in M_b$$

- Suppose $M \subseteq \mathbb{Q}$ was maximal and choose any $q \in \mathbb{Q}$ with $q \notin M$. Then $M + \mathbb{Z}q = \mathbb{Q}$, as M was maximal. Hence we find an epimorphism

$$\mathbb{Z} \twoheadrightarrow \mathbb{Q} \Big/ M \ : \ k \mapsto kq + M$$

Let $n\mathbb{Z}$ be the kernel of this homomorphism, then we have an isomorphy of $\mathbb{Z}_n \xrightarrow{\sim} \mathbb{Q}/M$ under the correspondence $k + n\mathbb{Z} \mapsto kq + M$. Composing the canonical epimorphism $\mathbb{Q} \twoheadrightarrow \mathbb{Q}/M : x \mapsto x + M$ with the inverse $\mathbb{Q}/M \xrightarrow{\sim} \mathbb{Z}_n$ we find another epimorphism

$$\varphi \ : \ \mathbb{Q} \twoheadrightarrow \mathbb{Z}_n \ : \ x \mapsto x + M = kq + M \mapsto k + n\mathbb{Z}$$

But a homomorphism of this form always is zero: Let $e := \varphi(1/1)$, then for any prime p we have $e = \varphi(p/p) = p\varphi(1/p)$. That is $p \mid e$ for any prime p and this only leaves $e = 0$. From this reasoning we then get $0 = e = \varphi(b/b) = b\varphi(1/b)$ for any $b \neq 0$, which means $\varphi(1/b) = 0$, such that $\varphi = 0$ altogether.

In particular $\varphi(q) = 0 + n\mathbb{Z}$, but $q + M$ also corresponds to $1 + n\mathbb{Z}$ such that $0 + n\mathbb{Z} = 1 + n\mathbb{Z}$, which means $n = 1$. That is $q + M = 0 + M$ or in other words $q \in M$. This finally is a contradiction, that can only be remedied, by dropping the assumption of the maximality of M.

□

Proof of (3.113):
The implication (b) $\implies$ (c) is easy to see, since any noetherian module V already is finitely generated. Conversely for (c) $\implies$ (b) we note that any field is noetherian - as it contains two ideals only. And as $V \cong_{\mathfrak{m}} F^n$ by assumption, it is the (n-times) direct product of a noetherian module and hence noetherian itself, according to (3.111.(iv))
The same argument holds true for (c) $\implies$ (a): Since F also is artinian and $V \cong_{\mathfrak{m}} F^n$ just is a finite direct sum of this, we likewise find that V is artinian, too. So it only remains to prove (a) $\implies$ (c): To do this let us start with a basis $\{ v_i \mid i \in I \}$ of V. To begin with, we let $I_0 := I$. Suppose I_0 to I_k have already been constructed, then we commence: If $I_k \neq \emptyset$ still is non-empty, choose some arbitrary $i(k+1) \in I_k$ and let $I_{k+1} := I_k \setminus \{ i(k+1) \}$. Always take $U_k := \mathrm{Lh}\{ v_i \mid i \in I_k \}$ the subspace generated by the v_i where $i \in I_k$. This means $U_k = U_{k+1} + Fv_{i(k+1)}$ and in particular $U_{k+1} \subset U_k$ [if we had $v_{i(k+1)} \in U_{k+1}$ this would contradict the linear independence of the basis]. Thus we found a strictly descending chain of subspaces

$$V = U_0 \supset U_1 \supset \ldots \supset U_n \supset \ldots$$

But since V is artinian, this chain has to stabilize, that is there is some $n \in \mathbb{N}$ such that we cannot continue our construction. And this can only occur if $I_n = \emptyset$, which means, that I was finite. □

Proof of (3.114):

- (a) $\implies$ (b): given any $x \in M$ with $x \neq 0$ we clearly know, that $P = Rx \leq_{\mathfrak{m}} M$ is a sub-module of M. And since $x = 1\,x \in P$ we have $P \neq 0$, which only leaves $M = Rx$, by assumption (a).

- (b) $\implies$ (a): consider any sub-module $P \leq_{\mathfrak{m}} M$ of M. If $P = 0$, then there is nothing to prove, else pick up some $x \in P$ with $x \neq 0$. Now we get $M = Rx$ by assumption (b), but as also $M = Rx \subseteq P \subseteq M$ this implies $P = M$.

- (b) $\implies$ (c): choose any $x \in M$ with $x \neq 0$, which is possible since $M \neq 0$ is non-zero. By assumption (b) we then have $M = Rx$. Now let $\mathfrak{m} := \mathrm{ann}(x) \trianglelefteq_{\mathfrak{i}} R$. Then by (3.22.(ii)) we have the following isomorphy of R-modules

 $$\Phi : R\big/_{\mathrm{ann}(x)} \xrightarrow{\sim} M : b + \mathrm{ann}(x) \mapsto bx$$

 Now suppose $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ is an ideal of R such that $\mathfrak{m} \subseteq \mathfrak{a}$. Then the above isomorphy transfers $\mathfrak{a}/\mathfrak{m}$ to a sub-module $P = \Phi(\mathfrak{a}) \leq_{\mathfrak{m}} M$ of M. But as (b) implies (a) this means $P = 0$ or $P = M$. In case $P = 0$ we have $\mathfrak{a} = \mathfrak{m}$ and in case $P = M$ we have $\mathfrak{a} = R$. This shows that $\mathfrak{m}$ even is a maximal ideal of M.

- (c) $\implies$ (a): suppose $\Phi : R/\mathfrak{m} \xrightarrow{\sim} M$ is that isomorphism of R-modules and consider some sub-module $P \leq_{\mathfrak{m}} M$ of M. Then $\mathfrak{a} := \Phi^{-1}(P) \leq_{\mathfrak{m}} R/\mathfrak{m}$ is an R-sub-module of $R/\mathfrak{m}$. As R is commutative it is clear that $\mathfrak{a}$ even is an ideal of $R/\mathfrak{m}$. But as $\mathfrak{m}$ is maximal, the only ideals of $R/\mathfrak{m}$ are 0 and $R/\mathfrak{m}$ itself. In case $\mathfrak{a} = 0$ we see $P = \Phi(\mathfrak{a}) = 0$ and in case $\mathfrak{a} = R/\mathfrak{m}$ we find $P = \mathrm{im}(\Phi) = M$. Hence 0 and M are the only sub-modules of M, as has been claimed in (a).

□

Proof of (3.117):
For the moment being - as long as we have not proved that the length of M is uniquely determined - let us denote by $\ell(M)$ the *minimum* length of of a composition series of M

$$\ell(M) \;:=\; \min\{\, r \in \mathbb{N} \mid (M_0, M_1, \ldots, M_r) \text{ composition series of } M \,\}$$

Also, given any two sub-modules U and $V \leq_{\mathsf{m}} M$, we denote the set of all chains of sub-modules that start in P and end in Q by $\mathcal{C}(U,V)$, that is

$$\mathcal{C}(U,V) \;:=\; \left\{ (P_0, P_1, \ldots, P_r) \;\middle|\; \begin{array}{l} \forall\, i \in 0 \ldots r : P_i \leq_{\mathsf{m}} M \\ U = P_0 \subset P_1 \subset \ldots \subset P_r = V \end{array} \right\}$$

And we say that two chains $(P_0, P_1, \ldots, P_r)$ and $(Q_0, Q_1, \ldots, Q_s)$ in $\mathcal{C}(U,V)$ are *equivalent*, written as $(P_{0,1}, \ldots, P_r) \sim (Q_0, Q_1, \ldots, Q_s)$, iff $r = s$ and there is some permutation $\sigma \in S_r$ such that for any $i \in 1 \ldots r$ we have the following isomorphy of the quotient modules

$$P_i \Big/ P_{i-1} \;\cong_{\mathsf{m}}\; Q_{\sigma(i)} \Big/ Q_{\sigma(i)-1}$$

And in this case we say that σ *assigns* the equivalence of $(P_0, P_1, \ldots, P_r)$ and $(Q_0, Q_1, \ldots, Q_r)$. Thereby $\sim$ truly is an equivalence relation: clearly $(P_0, P_1, \ldots, P_r) \sim (P_0, P_1, \ldots, P_r)$ is assigned by the identity $\mathbb{1} \in S_r$. And if $(P_0, P_1, \ldots, P_r) \sim (Q_0, Q_1, \ldots, Q_s)$ is assigned by $\sigma \in S_r$ then the reverse relation $(Q_0, Q_1, \ldots, Q_s) \sim (P_0, P_1, \ldots, P_r)$ is assigned by the inverse permutation $\sigma^{-1} \in S_r$. And finally, if $(N_0, N_1, \ldots, N_r) \sim (P_0, P_1, \ldots, P_s)$ is assigned by σ and $(P_0, P_1, \ldots, P_s) \sim (Q_0, Q_1, \ldots, Q_t)$ is assigned by τ then we also get the equivalence $(N_0, N_1, \ldots, N_r) \sim (Q_0, Q_1, \ldots, Q_t)$ that is assigned by the composition $\tau\sigma$, since

$$N_i \Big/ N_{i-1} \;\cong_{\mathsf{m}}\; P_{\sigma(i)} \Big/ P_{\sigma(i)-1} \;\cong_{\mathsf{m}}\; Q_{\tau(\sigma(i))} \Big/ Q_{\tau(\sigma(i))-1}$$

(i) Let $(M_0, M_1, \ldots, M_r)$ be a composition series of M of minimal length $r = \ell(M)$ and denote $P_i := M_i \cap P$. Let us also denote

$$\varphi_i \;:\; P_i \to M_i \Big/ M_{i-1} \;:\; x \mapsto x + M_{i-1}$$

then it is clear that $\mathrm{kn}(\varphi_i) = M_{i-1} \cap P = P_{i-i}$. Hence we find an R-module-monorphism (this is the first isomorphism theorem)

$$\Phi_i \;:\; P_i \Big/ P_{i-1} \;\hookrightarrow\; M_i \Big/ M_{i-1} \;:\; x + P_{i-1} \mapsto x + M_{i-1}$$

That is P_i/P_{i-1} is isomorphic to a sub-module of M_i/M_{i-1}. But as M_i/M_{i-1} is a simple module this implies $P_i/P_{i-1} = 0$ (which yields $P_i = P_{i-1}$) or Φ_i even is an isomorphism (which yields that P_i/P_{i-1} is simple again). Altogether

$$P_i \;=\; P_{i-1} \quad \text{or} \quad \Phi_i \text{ is an isomorphism}$$

Let us now omit those P_i with $P_i = P_{i-1}$, that is if we take to the index set $I := \{\, i \in 1 \ldots r \mid P_i \neq P_{i-1} \,\}$ and $q := (\#I) - 1$ then we may renumber the index set $I = \{\, \alpha(0), \alpha(1), \ldots, \alpha(q) \,\}$ with $0 = \alpha(0) <$

$\alpha(1) < \cdots < \alpha(q)$ and thereby obtain a composition series of P

$$0 \;=\; P_{\alpha(0)} \;\subset\; P_{\alpha(1)} \;\subset\; \ldots \;\subset\; P_{\alpha(q)} \;=\; P$$

Thereby $P_{\alpha(q)} = M_r \cap P = M \cap P = P$. Hence we have obtained a composition series of P of length $q \leq r$. Suppose we had $q = r$, then we did not omit any $i \in 0 \ldots r$, that is Φ_i is an isomorphsim for any $i \in 1 \ldots r$. Then we can prove $P_i = M_i$ for any $i \in 0 \ldots r$ by induction on r: Clearly $P_0 = 0 = M_0$ and if $P_{i-1} = M_{i-1}$ then, as Φ_i is surjective, it is just the identity map on M_i/M_{i-1}. In particular we get $P = M \cap P = M_r \cap P = P_r = M_r = M$ which contradicts the assumption $P \neq M$.

(iii) Recall that a composition series $(M_0, M_1, \ldots, M_r)$ of M is an element of $\mathcal{C}(0, M)$ such that every quotient M_i/M_{i-1} is simple. We will now prove, that any two composition series $(M_0, M_1, \ldots, M_r)$ and $(N_0, N_1, \ldots, N_s)$ of M are equivalent. Without loss of generality let us assume $r \leq s$, then we will use induction on the length r of the shorter chain. To be precise the induction hypothesis will be: If $(M_0, M_1, \ldots, M_r)$ and $(N_0, N_1, \ldots, N_s)$ are two composition series of some module $M_r = N_s$ of length $r \leq s$, then $(M_0, M_1, \ldots, M_r) \sim (N_0, N_1, \ldots, N_s)$ are equivalent already.

For $r = 0$ we have $0 = M_0 = M_r = M$, that is $M = 0$ and hence $s = 0$, too. Thus for $r = 0$ there is nothing to prove. Also if $r = 1$ then $M = M/0 = M_1/M_0$ and hence M is simple. Therefore $(0, M)$ is the only composition series of M, as M admits no other sub-modules. So from now on we only have to regard $r \geq 2$ and can assume that the induction hypothesis is already proved for length $\leq r - 1$.

As a first case let us assume $M_{r-1} \subseteq N_{s-1}$. Then we find the inclusions $M_{r-1} \subseteq N_{s-1} \subseteq M = M_r$. But as M_r/M_{r-1} is simple this already means $M_{r-1} = N_{s-1}$ as $N_{s-1} \neq N_s = M = M_r$. Hence

$$(M_0, M_1, \ldots, M_{r-1}) \;\sim\; (N_0, N_1, \ldots, N_{s-1})$$

by induction hypothesis. But as $M_r/M_{r-1} = M/M_{r-1} = M/N_{s-1} = N_s/N_{s-1}$ even is an equality of R-modules it is clear that this equivalence extends to an equivalence of the same chains, appended by M

$$(M_0, M_1, \ldots, M_{r-1}, M_r) \;\sim\; (N_0, N_1, \ldots, N_{s-1}, N_s)$$

Likewise, as a second case, we suppose $N_{s-1} \subseteq M_{r-1}$ then the inclusions $N_{s-1} \subseteq M_{r-1} \subseteq M = N_s$ imply $M_{r-1} = N_{s-1}$ as N_s/N_{s-1} is simple and $M_{r-1} \neq M_r = M = N_s$. Thus this case ends up in the same equivalence, as the first case.

So in the last case we may assume $M_{r-1} \not\subseteq N_{s-1}$ and $N_{s-1} \not\subseteq M_{r-1}$. Then we find the inclusions $M_{r-1} \subset M_{s-1} + N_{s-1} \subseteq M = M_r$ such that we get the equality $M_{r-1} + N_{s-1} = M$. Now let $P := N_{s-1} \neq M$ and $P_i := M_i \cap P$ as in (i) above. As we have seen there is some $q < r$ such that $\alpha(0) < \alpha(1) < \cdots < \alpha(q)$ satisfies

$$\{\, \alpha(0), \alpha(1), \ldots, \alpha(q) \,\} \;=\; I \;=\; \{\, i \in 1 \ldots r \mid P_i \neq P_{i-1} \,\}$$

Suppose we had $P_{r-1} = P_r = M_r \cap P = P$, then $M_{r-1} \cap P = P_{r-1} = P$ implies $N_{s-1} = P \subseteq M_{r-1}$

which has already been dealt with. Hence we have $P_r \neq P_{r-1}$ that is $r \in I$ and hence necessarily $\alpha(q) = r$. Let us finally abbreviate $Q_i := P_{\alpha(i)} = M_{\alpha(i)} \cap P$, then $Q_q = P_{\alpha(q)} = P_r = M_r \cap P = P = N_{s-1}$. Also, as $P_{r-1} \neq P_r$ we find from the construction of the $\alpha(i)$ that $Q_{q-1} = P_{r-1}$ (even though it might well be, that $P_{r-2} = P_{r-1}$ but this does not bother us). As we have seen in (i) the Q_i then form a composition series of $P = N_{s-1}$

$$0 \;=\; Q_0 \;\subset\; Q_1 \;\subset\; \ldots \;\subset\; Q_q \;=\; N_{s-1}$$

That is $(Q_0, Q_1, \ldots, Q_{q-1}, Q_q) = (Q_0, Q_1, \ldots, Q_{q-1}, N_{s-1})$. And as as $q \leq r-1$ we may use the induction hypothesis to obtain the equivalence $(Q_0, Q_1, \ldots, Q_{q-1}, N_{s-1}) \sim (N_0, N_1, \ldots, N_{s-1})$. In particular we may append these chains by N_s to finally arrive at

$$(Q_0, Q_1, \ldots, Q_{q-1}, N_{s-1}, N_s) \;\sim\; (N_0, N_1, \ldots, N_{s-1}, N_s)$$

We will now prove the equivalence of $(Q_0, Q_1, \ldots, Q_{q-1}, M_{r-1}, M_r)$ and $(Q_0, Q_1, \ldots, Q_{q-1}, N_{s-1}, N_s)$ which will be assigned by the transposition $\tau = (q-1\,q)$. That is we will prove the following isomorphies

$$M_{r-1}\Big/_{Q_{q-1}} \;\xrightarrow{\sim}\; N_s\Big/_{N_{s-1}} \;:\; x + Q_{q-1} \mapsto x + N_{s-1}$$

$$N_{s-1}\Big/_{Q_{q-1}} \;\xrightarrow{\sim}\; M_r\Big/_{M_{r-1}} \;:\; x + Q_{q-1} \mapsto x + M_{r-1}$$

The injectivity is clear from the definition, if $x \in M_{r-1}$ with $x + N_{s-1} = 0 + N_{s-1}$ then $x \in M_{r-1} \cap N_{s-1} = Q_{q-1}$. And likewise, if $x \in N_{s-1}$ with $x + M_{r-1} = 0 + M_{r-1}$ then $x \in N_{s-1} \cap M_{r-1} = Q_{q-1}$ again. Hence M_{r-1}/Q_{q-1} is isomorphic to a sub-module of the simple module N_s/N_{s-1}. But $M_{r-1} = Q_{q-1} = M_{r-1} \cap P$ would mean $M_{r-1} \subseteq P = N_{s-1}$ which has been dealt with in the first case. Hence here $x + Q_{q-1} \mapsto x + N_{s-1}$ is an isomorphism. Likewise N_{s-1}/Q_{q-1} is isomorphic to a sub-module of the simple module M_r/M_{r-1} but $N_{s-1} = Q_{q-1} = M_{r-1} \cap N_{s-1}$ would imply $N_{s-1} \subseteq N_{s-1}$ which has been dealt with in the second case. Hence $x + Q_{q-1} \mapsto x + M_{r-1}$ is an isomorphism, as well.

But as $q \leq r-1$ we may use the induction hypothesis once more to get the equivalence $(Q_0, Q_1, \ldots, Q_{q-1}, M_{r-1}) \sim (M_0, M_1, \ldots, M_{r-2}, M_{r-1})$. And again this can be appended, to $(Q_0, Q_1, \ldots, Q_{q-1}, M_{r-1}, M_r) \sim (M_0, M_1, \ldots, M_{r-2}, M_{r-1}, M_r)$. So summarizing all the results we have finally proved, that

$$\begin{aligned}(N_0, N_1, \ldots, N_{s-2}, N_{s-1}, N_s) \;&\sim\; (Q_0, Q_1, \ldots, Q_{q-1}, N_{s-1}, N_s)\\ &\sim\; (Q_0, Q_1, \ldots, Q_{q-1}, M_{r-1}, M_r)\\ &\sim\; (M_0, M_1, \ldots, M_{r-2}, M_{r-1}, M_r)\end{aligned}$$

(ii) Let $(P_0, P_1, \ldots, P_k)$ be a composition series of P and $(Q_0, Q_1, \ldots, Q_n)$ be a composition series of M/P. Due to the correspondence theorem any sub-module Q_i of M/P is of the form $Q_i = M_i/P$ for some sub-module $M_i \leq_{\mathfrak{m}} M$ with $P_k = P \subseteq M$. Then we get

$$M_1\Big/_{P_k} \;=\; M_1\Big/_{P} \;=\; Q_1 \;\cong_{\mathfrak{m}}\; Q_1\Big/_{0} \;=\; {}^{P_1}\Big/_{P_0}$$

That is: as P_1/P_0 is simple, so is M_1/P_k. Also due to the third isomorphism theorem (3.78) we

also find for any $i \in 1 \dots n$

$$Q_i \Big/ Q_{i-1} \;=\; M_i/P \Big/ M_{i-1}/P \;\xrightarrow{\sim}\; M_i \Big/ M_{i-1}$$

where this isomorphism is given by $(x+P)+(M_{i-1}/P) \mapsto x + M_{i-1}$ which is not important however. Thereby we have found, that any M_i/M_{i-1} is simple again, such that we can assemble a composition series of M by letting $(P_0, P_1, \dots, P_k, M_1, \dots, M_n)$. In particular M is of finite length and we have found the equality

$$\ell(M) \;=\; k+n \;=\; \ell(P) + \ell\left(M \Big/ P\right)$$

It remains to prove that conversely, if M has finite length, then P and M/P have finite length, too. The case of P has already been shown in (i), it remains to prove this for M/P. Hence let $(M_0, M_1, \dots, M_r)$ be a composition series of M, then we define

$$Q_i \;:=\; M_i + P \Big/ P \;\leq_{\mathsf{m}}\; M \Big/ P$$

It is clear that $Q_0 = P/P = 0$ and $Q_r = (M+P)/P = M/P$. And the third isomorphism theorem (3.78) yields the following isomorphy

$$M_i + P \Big/ M_{i-1} + P \;\cong_{\mathsf{m}}\; (M_i+P)/P \Big/ (M_{i-1}+P)/P \;=\; Q_i \Big/ Q_{i-1}$$

Explicitly this isomorphism is $x + (M_{i-1}+P) \mapsto (x+P) + Q_{i-1}$ but this doesn't matter, really. Let us now regard the following map

$$\Phi_i \;:\; M_i \Big/ M_{i-1} \;\to\; M_i + P \Big/ M_{i-1} + P \;:\; x + M_{i-1} \mapsto x + (M_{i-1} + P)$$

It is clear that Φ_i is surjective, given any $x \in M_i$ and $p \in P$ we see that $x + M_{i-1} \mapsto x + (M_{i-1} + P) = x + p + (M_{i-1} + P)$. And the kernel of Φ_i is obviously given to be

$$\mathsf{kn}(\Phi_i) \;=\; M_i \cap (M_{i-1}+P) \Big/ M_{i-1} \;\leq_{\mathsf{m}}\; M_i \Big/ M_{i-1}$$

But as M_i/M_{i-1} is simple this either means $\mathsf{kn}(\Phi_i) = 0$ (and hence Φ_i is injective, thereby bijective) or $\mathsf{kn}(\Phi_i) = M_i/M_{i-1}$ (and thereby $M_i \cap (M_{i-1}+P) = M_i$ which means $M_i \subseteq M_{i-1}+P$ such that $M_i + P = M_{i-1} + P$ which implies $Q_i = Q_{i-1}$). Altogether we have

$$M_i + P = M_{i-1} + P \;\text{ or }\; \Phi_i \text{ is an isomorphism}$$

Let us now take $I := \{\, 1 \dots r \mid Q_i \neq Q_{i-1} \,\}$, then for any $i \in I$ we have that Φ_i is an isomorphism, such that

$$M_i \Big/ M_{i-1} \;\cong_{\mathsf{m}}\; M_i + P \Big/ M_{i-1} + P \;\cong_{\mathsf{m}}\; Q_i \Big/ Q_{i-1}$$

That is for any $i \in I$ we find that Q_i/Q_{i-1} is a simple module. And for any $j \notin I$ we have seen $Q_j = Q_{j-1}$. Therefore we can pick up some indexes $0 \leq \alpha(0) < \alpha(1) < \dots < \alpha(n) \leq r$ such that $I = \{\, \alpha(0), \alpha(1), \dots, \alpha(n) \,\}$ and have found a composition series of M/P by $(Q_{\alpha(0)}, Q_{\alpha(1)}, \dots, Q_{\alpha(n)})$. In particular M/P has finite length again and the equivalence holds true.

We now turn our attention to the generalization of the above statement for any ascending chain $0 = P_0 \subseteq P_1 \subseteq P_2 \subseteq \ldots \subseteq P_n = M$ of sub-modules of M. For $n = 1$ the equality is clear, as $P_1/P_0 = M/0 = M$. For general n we use induction on n. By the above, we have

$$\ell(M) \;=\; \ell\left(M \Big/ P_{n-1}\right) + \ell\big(P_{n-1}\big)$$

Note that $P_n = M$ and use the induction hypothesis on P_{n-1} then we may express the length of P_{n-1} [and thereby of M] as the sum

$$\ell(M) \;=\; \ell\left(P_n \Big/ P_{n-1}\right) + \sum_{k=1}^{n-1} \ell\left(P_k \Big/ P_{k-1}\right) \;=\; \sum_{k=1}^{n} \ell\left(P_k \Big/ P_{k-1}\right)$$

(v) Without loss of generality we may assume $P_0 = 0$ and $P_k = M$. Because if $P_0 \neq 0$ or $P_k \neq M$ then we may append the series $(P_0, \ldots, P_k)$ to $(0, P_0, P_1, \ldots, P_k, M)$ which we will refine instead.

We will now prove this statement by induction on the length $r = \ell(M)$ of M. If $r = 0$ we have $M = 0$ and hence the only series of sumbodules of M is (0) which is a composition series already. Likewise for $r = 1$ we know that M is simple, such that $(0, M)$ is the only series of sub-modules which is a composition series already. Thus let us now assume the refinement-property has been established for any series of sub-modules in any R-module of length $r - 1$ or less.

If $k \leq 1$ then any composition series of M appends $(P_0, P_1) = (0, M)$. And as M was assumed to have finite length, there is some composition series. Thus we may regard the case $k \geq 2$. Then $0 \subset P_1 \subset M$ such that by (i) we have $\ell(P_1) < \ell(M) = r$ and by (ii) also $\ell(M/P_1) = \ell(M) - \ell(P_1) < \ell(M) = r$. By induction hypothesis we hence get a refinement $(L_0, L_1, \ldots, L_p)$ of $(0, P_1)$, that is $L_0 = 0$ and $L_p = P_1$. And denoting $Q_i := P_i/P_1$ for $i \in 1 \ldots k$, the induction hypothesis also yields a refinement $(N_1, N_2, \ldots, N_q)$ of $(Q_1, \ldots, Q_k)$. Thereby N_i is of the form $N_i = M_i/P_1$ for some $M_i \leq_{\mathsf{m}} M$ due to the correspondence theorem of modules. Therefore

$$M_{\alpha(i)} \Big/ P_1 \;=\; N_{\alpha(i)} \;=\; Q_i \;=\; P_i \Big/ P_1$$

which yields $M_{\alpha(i)} = P_i$ for $i \in 1 \ldots k$. We have seen in (ii) that $(L_0, L_1, \ldots, L_p, M_2, \ldots, M_q)$ is a composition series of M. And any P_i can be found inside of this composition series: $P_0 = L_0$, $P_1 = L_p = M_1$ and $P_i = M_{\alpha(i)}$ for any $i \in 2 \ldots k$. Hence $(L_0, L_1, \ldots, L_p, M_2, \ldots, M_q)$ is the refinement of $(P_0, P_1, \ldots, P_k)$ we sought.

(iv) It is clear that $\leq$ is a partial order on $\mathcal{C}(0, M)$, so we only have to prove the three equivalences. (a) $\implies$ (b): consider any refinement $(M_0, M_1, \ldots, M_r) \leq (N_0, N_1, \ldots, N_s)$, then by (v) we can choose a refinement of $(N_0, N_1, \ldots, N_s)$ to a composition series $(C_0, C_1, \ldots, C_t)$ of M. By (ii) the composition series has length $t = \ell(M) = r$. And thereby $r \leq s \leq t = r$ implies $r = s$, which means $(M_0, M_1, \ldots, M_r) = (N_0, N_1, \ldots, N_s)$. (b) $\implies$ (c): now suppose $(M_0, M_1, \ldots, M_r)$ was no composition series of M, that is there is some $i \in 1 \ldots r$ and some $Q \leq_{\mathsf{m}} M$ such that $M_{i-1} \subset Q \subset M_i$. Then we already had a true refinement of $(M_0, M_1, \ldots, M_r)$ by

$$(M_0, \ldots, M_r) \;<\; (M_0, \ldots, M_{i-1}, Q, M_i, \ldots, M_r)$$

such that $(M_0, M_1, \ldots, M_r)$ could not have been maximal. Finally the implication (c) $\implies$ (a) has

already been proved in (iii).

(vi) Consider any $\varphi_i : M_{i-1} \to M_i$ then, by the first isomorphism theorem, we have $M_{i-1}/\mathrm{kn}(\varphi_i) \xrightarrow{\sim} \mathrm{im}(\varphi_i)$ and hence by (ii)

$$\ell(\mathrm{kn}(\varphi_i)) + \ell(\mathrm{im}(\varphi_i)) \;=\; \ell(\mathrm{kn}(\varphi_i)) + \ell\left(M_{i-1} \Big/ \mathrm{kn}(\varphi_i)\right) \;=\; \ell(M_{i-1})$$

Now recall that the i-th homology module is defined by $H_i := \mathrm{kn}(\varphi_{i+1})/\mathrm{kn}(\varphi_i)$, then the claim follows by easy computation using (ii) again

$$\begin{aligned}
\sum_{i=0}^{n}(-1)^i\ell(H_i) &= \sum_{i=0}^{n}(-1)^i\ell\left(\mathrm{kn}(\varphi_{i+1}) \Big/ \mathrm{kn}(\varphi_i)\right) \\
&= \sum_{i=0}^{n}(-1)^i\left[\ell(\mathrm{kn}(\varphi_{i+1})) - \ell(\mathrm{kn}(\varphi_i))\right] \\
&= \sum_{i=1}^{n+1}(-1)^{i-1}\ell(\mathrm{kn}(\varphi_{i+1})) - \sum_{i=0}^{n}(-1)^i\ell(\mathrm{kn}(\varphi_i)) \\
&= \sum_{i=1}^{n}(-1)^{i-1}\left[\ell(\mathrm{kn}(\varphi_i)) + \ell(\mathrm{kn}(\varphi_i))\right] \\
&\quad +(-1)^n\ell(\mathrm{kn}(\varphi_{n+1})) - \ell(\mathrm{im}(\varphi_0)) \\
&= \sum_{i=1}^{n}(-1)^{i-1}\ell(M_i) + (-1)^n\ell(M_n) - \ell(0) \\
&= \sum_{i=0}^{n}(-1)^i\ell(M_i)
\end{aligned}$$

□

Proof of (3.119):
Let us denote the quotient ring $Q := R/\mathrm{ann}(M)$. If now M is an R-module, then M can also be turned into a Q-module under the scalar multiplication $(b + \mathrm{ann}(x)) := bx$ as has been shown in (3.22.(v)). And from this construction it is clear that (for any $X \subset M$)

$$\mathrm{Lh}_R(X) \;=\; \mathrm{Lh}_Q(X)$$

In particular the Q-sub-modules of M are precisely the R-sub-modules of M. And therefore it is equivalent whether M is noetherian (resp. artinian) as an R-module or an an Q-module. This will be used in the proof of (i) and (ii).

(i) If M is noetherian, then in particular it is finitly generated by property (c) of noetherian modules. And also, if M is noetherian, then M^n is noetherian by (3.111.(iv)). But by (3.23.(iv)) we find an embedding $Q \hookrightarrow M^n$ of R-modules (where $n = \mathrm{rank}(M)$). That is, there is an isomorphic copy of Q as an R-sub-module of M^n. As M^n is noetherian this implies, that Q is a noetherian R-module, hence a noetherian Q-module and hence a noetherian ring.

Conversely suppose Q is a noetherian ring and M a finitly generated R-module. Then Q is finitely generated as an Q-module (using the same generators) and hence a noetherian Q-module by virtue of (3.111.(vi)). But this again means that M is a noetherian R-module, as well.

(ii) If M is artinian, then M^n is artinian by (3.111.(iv)). But by (3.23.(iv)) we find an embedding $Q \hookrightarrow M^n$ of R-modules (where $n = \mathrm{rank}(M)$, which is finite by assumption). That is, there is an isomorphic copy of Q as an R-sub-module of M^n. As M^n is artinian this implies, that Q is an artinian R-module, hence an artinian Q-module and hence an artinian ring.

Conversely suppose Q is an artinian ring and M a finitely generated R-module. Then Q is finitely generated as an Q-module (using the same generators) and hence an artinian Q-module by virtue of (3.111.(vi)). But this again means that M is an artinian R-module, as well.

(iii) If M is finitely generated and artinian then $Q = R/\mathrm{ann}(M)$ is an artinian ring by virtue of (ii). But from (2.40.(ii)) we know that any artinian ring already is noetherian. Hence Q is noetherian and M is finitely generated, such that M is noetherian by (i).

(iv) Let us regard $K_n := \mathrm{kn}(\varphi^n) \leq_{\mathfrak{m}} M$, then it is clear that the K_n form an ascending chain of sub-modules of M

$$K_0 \subseteq K_1 \subseteq K_2 \subseteq \dots$$

As M is noetherian this chain has to stabilize at some point $s \in \mathbb{N}$, that is $K_{s+1} = K_s$. Now consider any $y \in \mathrm{kn}(\varphi)$, as φ is surjective so is $\varphi^s : M \to M$. Hence there is some $x \in M$ such that $y = \varphi^s(x)$. Now $0 = \varphi(y) = \varphi(\varphi^s(x)) = \varphi^{s+1}(x)$ that is $x \in K_{s+1} = K_s$. That is $y = \varphi^s(x) = 0$ which implies that φ already is injective, as well.

(v) Let us regard $I_n := \mathrm{im}(\varphi^n) \leq_{\mathfrak{m}} M$, then it is clear that the I_n form a descending chain of sub-modules of M

$$I_0 \supseteq I_1 \supseteq I_2 \supseteq \dots$$

As M is artinian this chain has to stabilize at some point $s \in \mathbb{N}$, that is $I_{s+1} = I_s$. Now consider any $y \in M$, as $\pi^s(y) \in I_s = I_{s+1}$ there is some $x \in M$ such that $\varphi^s(y) = \varphi^{s+1}(x) = \varphi^s(\varphi(x))$. As φ is injective, so is $\pi^s : M \to M$ and hence we find $y = \varphi(x)$. As y has been arbitrariy this means that φ already is surjective.

(vi) Let us first suppose that $r = \ell(M) < \infty$ that is M admits a composition series $(M_0, M_1, \dots, M_r)$. We will prove that M is noetherian and artinian by induction on r. If $r = 0$ then $M = 0$ so there is nothing to prove. And if $r = 1$ then M is simple and hence $0 \subseteq M$ is the only chain of sub-modules of M. In particular M is noetherian and artinian. Let now r be aritrary and suppose the claim has been proved for any module of length less than r. As M_1 is simple it is noetherian and artinian as we have argued for $r = 1$. Also by (3.117.(ii)) we have $\ell(M/M_1) = \ell(M) - \ell(M_1) < \ell(M) = r$ so by induction hypothesis M/M_1 is noetherian and arininan too. But (3.111.(i)) now implies that M is noetherian and artinian, as well.

Conversely suppose M is both, artinian and noetherian. Then we have to prove that M is of finite length. To do this define the set $\mathcal{K}$ of all those sub-modules of M that have a composition series

$$\mathcal{K} := \{ K \leq_{\mathfrak{m}} M \mid \ell(K) < \infty \}$$

As $0 \in \mathcal{K}$ we see that $\mathcal{K}$ is non-empty and hence (as M is noetherian) has a maximal element $K^* \in \mathcal{K}$. By construction K^* has a composition series, say $(K_0, K_1, \dots, K_r)$. Now suppose we had

$K^* \neq M$, then we take to the set $\mathcal{L}$ of all sub-modules of M that strictly contain K^*

$$\mathcal{L} \;:=\; \{\, L \;\leq_{\mathsf{m}}\; M \mid K^* \subset L \,\}$$

As $K^* \neq M$ we have $M \in \mathcal{L}$ such that $\mathcal{L}$ is non-empty. Hence (as M also is artinian) there is a minimal element $L_* \in \mathcal{L}$. Now suppose there is some sub-module $P \leq_{\mathsf{m}} M$ with $K^* \subseteq P \subseteq L_*$. If $P \neq K^*$ then $P = L_*$ as L_* is minimal with this property. That is L_*/K^* is simple and hence we find a composition series of L_* by $(K_0, K_1, \ldots, K_r, L_*)$. But remember, K^* has been maximal among those sub-modules of M that admit a composition series so it cannot be extended to $K^* \subset L_*$. Hence the assumption $K^* \neq M$ has to be false and in particular $M = K^*$ itself has a composition series.

(vii) We start with (d) $\implies$ (b), but in fact we have just seen in (vi) that a module of finite length is both, artinian and noetherian. For (b) $\implies$ (c) there is nothing to do either, as *any* sub-module of a noetherian module is finitely generated - in particular M itself. And (c) $\implies$ (a) is true, since R was assumed to be artinian and we have (3.111.(vi)). So it only remains to prove (a) $\implies$ (d): Let $\mathfrak{j} := \textsc{jac}(R)$ be the Jacobson radical of R. As R is artinian $\mathfrak{j}$ is nilpotent, that is there is some $n \in \mathbb{N}$ such that $\mathfrak{j}^n = 0$, due to (2.40.(v)). Now define (for any $k \in 1 \ldots n$)

$$Q_k \;:=\; \mathfrak{j}^{k-1}M \Big/ \mathfrak{j}^k M$$

e.g. $Q_1 = M/\mathfrak{j}M$. As $\mathfrak{j}^{k-1}M$ is a sub-module of M it is artinian, too and hence Q_k is artinian, being the quotient of an artinian module. We will now prove, that any Q_k has finite length only. This will then ensure, that M is of finite length, as well, since by the remark (iii) following the theorem of Jordan-Hölder (3.117) we know

$$\ell(M) \;=\; \sum_{k=1}^{n} \ell(Q_k)$$

Let $S := R/\mathfrak{j}$, then Q_k can be regarded as an S-module, as any sub-module of Q_k allows the scalar multiplication $(a + \mathfrak{j})(x + \mathfrak{j}^k M) = ax + \mathfrak{j}^k M$. ?? Grünes Buch S. 563 Aufgabe 2

(viii) First of all (e) $\implies$ (d), as for any $i \in 1 \ldots n$ we can take $N_i := M_1 \oplus \cdots \oplus M_i \oplus 0 \oplus \cdots \oplus 0 \;\leq_{\mathsf{m}} M$. To be precise also let $N_0 := 0 \;\leq_{\mathsf{m}} M$ then for any $i \in 1 \ldots n$ we clearly have the isomprphy $M_i \;\xrightarrow{\sim}\; N_i/N_{i-1} : x_i \mapsto x_i + M_{i-1}$ and in particular M_i/M_{i-1} is simple, by assumption (e). Therefore $(N_0, N_1, \ldots, N_r)$ is a composition series of M such that $\ell(M) = r < \infty$ is finite.

The implications (d) $\implies$ (a) and (d) $\implies$ (b) have already been shown in (vi). Also (b) $\implies$ (c) is clear, as *any* sub-module of a noetherian module is finitely generated, in particular M itself.

We will now prove (c) $\implies$ (e): as M is finitely generated we may pick up some $x_k \in M$ such that $M = \mathrm{Lh}(x_1, \ldots, x_n)$. By assumption M is semi-simple, that is there are some simple sub-modules $M_i \leq_{\mathsf{m}} M$ such that

$$M \;=\; \bigoplus_{i \in I} M_i$$

That is any x_k can be written as a *finite* sum of some elements $x_{k,i} \in M_i$ and hence there is some

finite subset $\Omega(k) \subseteq I$ such that

$$x_k \;=\; \sum_{i\in\Omega(k)} x_{k,i}$$

As $n \in \mathbb{N}$ is finite and any $\Omega(k) \subseteq I$ is finite, so is the union $\Omega := \Omega(1) \cup \cdots \cup \Omega(n)$ of these sets. And as the x_k generate M we see that M in fact is a finite direct sum, as claimed

$$M \;=\; \bigoplus_{i\in\Omega} M_i$$

Hence we have established the chain (e) $\implies$ (d) $\implies$ (b) $\implies$ (c) $\implies$ (e). And as we already know (d) $\implies$ (a) as well, it suffices to prove (a) $\implies$ (e): as M is semi-simple we have $M = \oplus_i M_i$ as above. Thereby we may omit all those $i \in I$ with $M_i = 0$. Now suppose I was infinite, then there was some injection $\alpha : \mathbb{N} \hookrightarrow I$. Then we take $I(k) := I \setminus \{\, \alpha(j) \mid j \leq k \,\}$ for any $k \in \mathbb{N}$ and let

$$N_k \;:=\; \bigoplus_{i\in I(k)} M_i$$

Then it is clear that the N_k form a strictly descending chain of sub-modules of M, that is $N_0 \supset N_1 \supset N_2 \supset \ldots$ in contradiction to M being artinian. Hence I could not have been infinite such that (e) holds true.

If now M even is a vector-space, that is R is a field, then clearly M is finitely generated if and only if M is finite dimensional. Hence (f) is equivalent to (c) and therefore to any other of the statements, as well.

(ix) Let us denote the set of all ideal-induced sub-modules $\mathfrak{a}M$ of M such that $M/\mathfrak{a}M$ *is* noetherian by $\mathcal{P}$

$$\mathcal{P} \;:=\; \left\{\, \mathfrak{a}M \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} R,\; {}^{M}\big/_{\mathfrak{a}M} \text{ is not noetherian} \,\right\}$$

Suppose M was not noetherian, then $0 \in \mathcal{P}$ and hence $\mathcal{P}$ is not empty. By assumption and (0.25) $\mathcal{P}$ then contains a maximal element $\mathfrak{a}^*M$. Let us now denote

$$M' \;:=\; {}^{M}\big/_{\mathfrak{a}^*M} \quad\text{and}\quad A \;:=\; {}^{R}\big/_{\mathrm{ann}(M')}$$

Then A is a commutative ring again and we can regard M' as an A-module. Note that by construction M' is *not* noetherian. Now, given any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} A$ in A, by the correspondence theorem $\mathfrak{a}$ is of the form $\mathfrak{a} = \mathfrak{b}/\mathrm{ann}(M')$ for some $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ with $\mathrm{ann}(M') \subseteq \mathfrak{b}$. We will now prove

$$\mathfrak{a}^* \;\subseteq\; \mathfrak{b}$$

To do this regard any $a \in \mathfrak{a}^*$ then for any $x \in M$ we get $ax \in \mathfrak{a}^*M$. That is $a(x + \mathfrak{a}^*M) = ax + \mathfrak{a}^*M = 0 + \mathfrak{a}^*M$ and hence $a \in \mathrm{ann}(M') \subseteq \mathfrak{b}$. As a has been arbitrary this proves $\mathfrak{a}^* \subseteq \mathrm{ann}(M') \subseteq \mathfrak{b}$. Now, by construction it is clear that $\mathfrak{a}M' = \mathfrak{b}M/\mathfrak{a}^*M$. And thereby the third isomorphism theorem yields

$${M'}\big/_{\mathfrak{a}M'} \;=\; {M/\mathfrak{a}^*M}\big/_{\mathfrak{b}M/\mathfrak{a}^*M} \;\cong_{\mathrm{m}}\; {M}\big/_{\mathfrak{b}M}$$

But as $\mathfrak{a}^* \subseteq \mathfrak{b}$ and $\mathfrak{a}^*$ has been maximal this implies either $\mathfrak{a}^* = \mathfrak{b}$ (and hence $\mathfrak{a} = 0$) or $M'/\mathfrak{a}M'$

is noetherian. Now let

$$\mathcal{Q} \;:=\; \left\{ Q \leq_{\mathfrak{m}} M' \mid \operatorname{ann}_A\left(M' \Big/ Q\right) = 0 \right\}$$

Recall $A = R/\operatorname{ann}_R(M')$ and that the scalar multiplication of M' (with A) is defined by $(a + \operatorname{ann}(M'))(x + \mathfrak{a}^* M) = ax + \mathfrak{a}^* M$. Therefore we have $\operatorname{ann}_A(M') = \operatorname{ann}_R(M')/\operatorname{ann}_R(M') = 0 \subseteq A$ such that $0 \in \mathcal{Q}$. In particular $\mathcal{Q}$ is non-empty.

If now $(Q_i) \subseteq \mathcal{Q}$ is a chain in $\mathcal{Q}$ then we take $Q := \bigcup_i Q_i$ to be the union of the Q_i. As (Q_i) is a chain Q is a sub-module of M' again. Consider any $a \in A$ with $a \in \operatorname{ann}_A(M'/Q) = 0$, that is $a(M'/Q) = 0$ or in other words $aM' \subseteq Q$. As M is finitely generated, so is M' say $M' = \mathrm{Lh}(x_1, \ldots, x_n)$, then we have $ax_k \in Q$ for any $k \in 1 \ldots n$ and hence $ax_k \in Q_{i(k)}$ for some $i(k) \in I$. As the Q_i form a chain we may take Q_i to be the maximum of $Q_{i(1)}$ to $Q_{i(n)}$. Then for any $k \in 1 \ldots n$ we have $ax_k \in Q_i$. But as the x_k generate M' this implies $aM' \subseteq Q_i$ and therefore $a \in \operatorname{ann}(M'/Q_i) = 0$ such that $a = 0$. That is $\operatorname{ann}_A(M'/Q) = 0$ and hence $Q \in \mathcal{Q}$ again. Hence any chain (Q_i) of $\mathcal{Q}$ has an upper bound Q and hence the lemma of Zorn yields a maximal element Q^* of $\mathcal{Q}$. Now take to

$$M'' \;:=\; M' \Big/ Q^*$$

If $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} A$ is any ideal with $\mathfrak{a} \neq 0$ then by (3.40.(v)) we have $\mathfrak{a}M'' = (\mathfrak{a}M' + Q^*)/Q^*$. Therefore the third isomorphism theorem again yields

$$M'' \Big/ \mathfrak{a}M'' \;=\; M'/Q^* \Big/ (\mathfrak{a}M' + Q^*)/Q^* \;\cong_{\mathfrak{m}}\; M' \Big/ \mathfrak{a}M' + Q^*$$

As we have shown before we have $\mathfrak{a}^* \subseteq \mathfrak{b}$ for $\mathfrak{a} = \mathfrak{b}/\operatorname{ann}(M')$. But as $\mathfrak{a} \neq 0$ and $\mathfrak{a}^*$ has been maximal we find that $M'/\mathfrak{a}M'$ is noetherian. But as we also have an epimorphism

$$M' \Big/ \mathfrak{a}M' \;\twoheadrightarrow\; M' \Big/ \mathfrak{a}M' + Q^*$$

This implies that $M'/(\mathfrak{a}M' + Q^*)$ is noetherian. By the above isomorphism, this makes $M''/\mathfrak{a}M''$ noetherian. So at last we have arrived at an A-module $N := M''$ that satisfies the following two properites

$$\forall\, \mathfrak{a} \trianglelefteq_{\mathfrak{i}} A \,:\, \mathfrak{a} \neq 0 \implies N \Big/ \mathfrak{a}N \text{ is noetherian}$$

$$\forall\, Q \leq_{\mathfrak{m}} N \,:\, Q \neq 0 \implies \operatorname{ann}\left(N \Big/ Q\right) \neq 0$$

We will now prove that $N = M''$ is noetherian by showing, that any sub-module of N is finitely generated: So suppose $Q \leq_{\mathfrak{m}} N$ is any sub-module of N. If $Q = 0$ then there is nothing to show, else there is some $a \in A$ with $a \neq 0$ such that $a(N/Q) = 0$, that is $aN \subseteq Q$. But as $aA \neq 0$ we know that N/aN is noetherian and hence $Q/aN \leq_{\mathfrak{m}} N/aN$ is finitely generated. And as M is finitely generated, so are $N = M''$ and aN. But as both Q/aN and aN are finitely generated (3.96) tells us that Q is finitely generated.

By now we have established that $N = M'' = M\ /Q^*$ is noetherian. Therefore (i) implies that $A/\operatorname{ann}(N)$ is a noetherian ring. Yet by construction we have $\operatorname{ann}(N) = \operatorname{ann}(M'/Q^*) = 0$ such that $A/\operatorname{ann}(N) = A$. That is A is a noetherian ring. Yet M' is a finitely generated A-module such that (3.111.(vi)) implies that $M' = M/\mathfrak{a}^* M$ *is* noetherian. But we have constructed M' is such a

way, as to be *not* noetherian. This contradiction can only be solved, if M has been noetherian from the start.

□

Proof of (2.46):

(i) If R is a field, then it clearly is an integral domain and artinin, as well as in this case the only ideals of R are 0 and R itself. In the converse direction regard any $0 \neq a \in R$, then we obtain a descending chain of ideals

$$aR \supseteq a^2R \supseteq \ldots \supseteq a^nR \supseteq a^{n+1}R \supseteq \ldots$$

Since R is artinian this chain has to stabilize, say at $n \in \mathbb{N}$. Hence $a^n \in a^nR = a^{n+1}R$. That is there is some $b \in R$ such that $a^n = a^{n+1}b$ which yields $a^n(1-ab) = 0$. But since R also is an integral domain and $a \neq 0$ this implies $ab = 1$ and hence $a \in R^*$ is invertible. Since $a \neq 0$ has been arbitrary this means, that R is a field.

(iii) If $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ is a prime ideal, then $Q := R/\mathfrak{p}$ is an integral domain by (2.12) and artinian by (2.40.(i)). But in (i) we have seen, that hence Q must be a field and hence $\mathfrak{p}$ is a maximal ideal, according to (2.5). This means we have proved

$$\mathrm{Spec}(R) = \mathrm{Smax}(R)$$

Now consider any prime ideal $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$, by (2.18.(iv)) there is a minimal prime ideal $\mathfrak{p}_*$ underneath $\mathfrak{p}$ - that is $\mathfrak{p}_* \subseteq \mathfrak{p}$, just take $\mathfrak{a} = 0$ to impose no restrictions. But since $\mathfrak{p}_*$ is prime, it already is maximal in the artinian ring R. Hence we get $\mathfrak{p}_{ast} = \mathfrak{p}$. And as $\mathfrak{p}$ has been arbitrary, this shows >that any prime ideal of R already is minimal

$$\mathrm{Spec}(R) = \mathrm{Smin}(R)$$

(iv) Suppose $\{ \mathfrak{m}_i \mid i \in \mathbb{N} \}$ were infinitely many distinct maximal ideals of R. Then by (2.9) we would get a strictly descending chain of ideals in R, by taking to

$$\mathfrak{m}_1 \supset \mathfrak{m}_1\mathfrak{m}_2 \supset \mathfrak{m}_1\mathfrak{m}_2 \ldots \mathfrak{m}_n \supset \mathfrak{m}_1\mathfrak{m}_2 \ldots \mathfrak{m}_n\mathfrak{m}_{n+1} \supset \ldots$$

But this of course contradicts R being an artinian ring. Hence R could only have had finitely many maximal ideals, to begin with.

(v) Let $\mathfrak{j} := \mathrm{JAC}(R)$ be the jacobson radical of R, then we regard the following descending chain of ideals of R

$$\mathfrak{j} \supseteq \mathfrak{j}^2 \supseteq \ldots \supseteq \mathfrak{j}^n \supseteq \mathfrak{j}^{n+1} \supseteq \ldots$$

Since R is artinian this chain has to stabilize, that is there is some $n \in \mathbb{N}$ such that $\mathfrak{j}^n = \mathfrak{j}^{n+1}$. Suppose we had $\mathfrak{j}^n \neq 0$, then set of ideals $\mathcal{A} := \{ \mathfrak{a} \trianglelefteq_{\mathfrak{i}} R \mid \mathfrak{j}^n\mathfrak{a} \neq 0 \} \neq \emptyset$ would be non-empty, as it contains R. Still R is artinian so we may choose a minimal ideal $\mathfrak{a} \in \mathcal{A}_*$ satisfying $\mathfrak{j}^n\mathfrak{a} \neq 0$. Now we observe

$$\mathfrak{j}^n(\mathfrak{j}\mathfrak{a}) = \mathfrak{j}^{n+1}\mathfrak{a} = \mathfrak{j}^n\mathfrak{a} \neq 0$$

That is $\mathfrak{ja}$ is another ideal satisfying $\mathfrak{j}^n(\mathfrak{ja}) \neq 0$. But as $\mathfrak{a}$ was minimal with this property and also $\mathfrak{ja} \subseteq \mathfrak{a}$ we must have $\mathfrak{ja} = \mathfrak{a}$.

On the other hand, since $\mathfrak{ja} \neq 0$ there have to be some $j \in \mathfrak{j}$ and $a \in \mathfrak{a}$ such that $ja \neq 0$. Therefore $\mathfrak{j}(aR) \neq 0$, as well. And as $\mathfrak{a}$ has been minimal with this property and $aR \subseteq \mathfrak{a}$ we also find that $\mathfrak{a} = aR$ is a principal ideal. In particular $\mathfrak{a}$ is a finitely generated R-module.

Now, as $\mathfrak{j}^n \subseteq \mathfrak{j} = \text{JAC}(R)$ and $\mathfrak{j}^n\mathfrak{a} = \mathfrak{a}$ we may apply Nakayama's lemma (3.44.(ii)) to find $\mathfrak{a} = 0$. This of course contradicts $\mathfrak{j}^n\mathfrak{a} \neq 0$. So $\mathfrak{a}$ could not have been chosen in the first place, which means $\mathcal{A} = \emptyset$. But this can only happen, if $\mathfrak{j}^n = 0$ already.

Finally consider any $j \in \mathfrak{j} = \text{JAC}(R)$, then j already has to be nilpotent, as $j^n \in \mathfrak{j}^n = 0$. As this is true for any $j \in \mathfrak{j}$ we have shown the first inclusion in the chain [refer to (2.25.(ii))]

$$\text{JAC}(R) \subseteq \text{NIL}(R) = \bigcap \text{Spec}(R) \subseteq \text{Smax}(R) = \text{JAC}(R)$$

(vi) By (iv) we already know that R has finitely many maximal ideals only, say $\{ \mathfrak{m}_1, \mathfrak{m}_2, \ldots, \mathfrak{m}_r \}$ And in (v) we have seen that the nil radical is the jacobson radical

$$\text{NIL}(R) = \text{JAC}(R) = \bigcap_{i=1}^{r} \mathfrak{m}_i$$

But as (powers of) distinct maximal ideals are coprime $\mathfrak{m}_i + \mathfrak{m}_j = R$ according to (2.9) we may just employ the Chinese remainder theorem (1.99.(iii)) to find precisely the isomorphism of the claim.

(vii) Again let $\{ \mathfrak{m}_1, \mathfrak{m}_2, \ldots, \mathfrak{m}_r \}$ be the set of distinct maximal ideals of R. Also let $\mathfrak{j} = \text{JAC}(R)$ be the jacobson radical of R, of which we know $\mathfrak{j}^n = 0$ due to (v). Then we compute

$$\bigcap_{i=1}^{r} \mathfrak{m}_i^n \subseteq \left(\bigcap_{i=1}^{r} \mathfrak{m}_i \right)^n = \mathfrak{j}^n = 0$$

Note that the ideals $\mathfrak{a}_i := \mathfrak{m}_i^n$ are coprime, since they are powers of maximal ideals (2.9) such that the Chinese remainder theorem (1.99.(iii)) once again yields our isomorphy

$$R \Big/ \mathfrak{a} \cong_{\text{r}} \bigoplus_{i=1}^{r} R \Big/ \mathfrak{a}_i$$

As we have argued above we find $\mathfrak{a} = \mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_r = 0$, such that $R/\mathfrak{a}$ is canonically isomorphic to R. Also any of the rings $L_i := R/\mathfrak{a}_i$ is a local ring, as it is one of the examples following proposition (2.136). Its maximal ideal is given to be $\mathfrak{m}_i/\mathfrak{a}_i$.

(ii) Let us first assume, R is a local, artinian ring and denote its maximal ideal by $\mathfrak{m}$. Then clearly $\mathfrak{m} = \text{JAC}(R)$ and hence there is some $n \in \mathbb{N}$ such that $\mathfrak{m}^n = 0$, according to (v). Now regard

$$Q_k := \mathfrak{m}^{k-1} \Big/ \mathfrak{m}^k$$

e.g. $F := Q_1 = R/\mathfrak{m}$ is a field. The other Q_k are R-modules, but we can also consider them to be F-vector spaces under the scalar multiplication $(a + \mathfrak{m})(x + \mathfrak{m}^k) = ax + \mathfrak{m}^k$. Since R is artinian (as an R-module) so are its sub-modules $\mathfrak{m}^{k-1}$. Hence the Q_k are artinian R-modules,

being quotients of such. As any R-sub-module of Q_k already is a F-subspace, the R-sub-modules and F-subspaces are precisely the same sets (3.40.(ix)). Hence they also are artinian as F-vector spaces.

But by (3.113) this means that any Q_k is finite-dimensional vector space and hence noetherian. As both $Q_n \cong_{\mathfrak{m}} \mathfrak{m}^{n-1}$ and $Q_{n-1} = \mathfrak{m}^{n-2}/\mathfrak{m}^{n-1}$ are noetherian, so is $\mathfrak{m}^{n-2}$, according to (3.111.(i)). By induction we find that R is noetherian as an R-module and hence as a ring.

If R is not local, then by (vii) it still is isomorphic to a direct sum of local artinian rings L_i. And as we have just seen, any L_i is a noetherian ring. Hence by (2.40.(iii)) $L_1 \oplus \cdots \oplus L_r$ is a noetherian ring, due to the isomorphy, so is R.

□

Proof of (2.37):
Let $\mathcal{I} := \{ \mathfrak{a} \subseteq R \mid \mathfrak{a} \trianglelefteq_{\mathfrak{i}} R \}$ denote the set of ideals of R. Then we can install a partial order on $\mathcal{I}$ by letting $\mathfrak{a} \leq \mathfrak{b}$ if and only is $\mathfrak{b} \subseteq \mathfrak{a}$. Then the equivalence (a) $\iff$ (b) is just an application of (0.25) to the partially ordered set $(\mathcal{I}, \leq)$.

The main part (a) $\implies$ (f) of the theorem has already been proved in (ii), (iv) and (v) of (2.46). And the implication (f) $\implies$ (e) is easy to see: We need to prove $\mathrm{Spec}(R) \subseteq \mathrm{Smax}(R)$, so let $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ be any prime ideal of R. By assumption $\sqrt{0} = \mathrm{NIL}(R) = \mathrm{JAC}(R) = \mathfrak{m}_1 \cap \cdots \cap \mathfrak{m}_r$ where $\mathfrak{m}_1$ to $\mathfrak{m}_r$ are the distinct maximal ideals of R. Then by (2.9)

$$\mathfrak{m}_1 \cdot \ldots \cdot \mathfrak{m}_r \;=\; \mathfrak{m}_1 \cap \ldots \cap \mathfrak{m}_r \;=\; \sqrt{0} \;\subseteq\; \mathfrak{p}$$

and as $\mathfrak{p}$ is prime, this means $\mathfrak{m}_i \subseteq \mathfrak{p}$ for some $i \in 1 \ldots r$. But as $\mathfrak{m}_i$ is maximal and $\mathfrak{p} \neq R$ this implies $\mathfrak{m}_i = \mathfrak{p}$ and in particular $\mathfrak{p}$ is maximal.

The next step (e) $\implies$ (d) uses another major theorem, the structure theorem of noetherian modules (5.14). By assumption R is a noetherian ring and thereby a noetherian R module. Hence there is a finite ascending chain of sub-modules

$$0 \;=\; M_0 \;\subset\; M_1 \;\subset\; \ldots \;\subset\; M_n \;=\; R$$

where every quotient $Q_k := M_k/M_{k-1}$ is isomorphic (as an R-module) to $R/\mathfrak{p}_k \xrightarrow{\sim} Q_k$ for some prime ideal $\mathfrak{p}_k \in \mathrm{Spec}(R)$. But by assumption we have $\mathrm{Spec}(R) = \mathrm{Smax}(R)$ these $\mathfrak{p}_k \trianglelefteq_{\mathfrak{i}} R$ already are maximal and hence $\ell(R/\mathfrak{p}_k) = 1$, as $0 \subset R/\mathfrak{p}_k$ is the one and only composition series of $R/\mathfrak{p}_k$. In particular we find

$$\ell(R) \;=\; \sum_{k=1}^{n} \ell(Q_k) \;=\; \sum_{k=1}^{n} 1 \;=\; n \;<\; \infty$$

The last step (d) $\implies$ (a) is trivial, as any (descending or ascending) chain of ideals (equivalently of R-sub-modules) has $\ell(R)$ as an upper bound.

By now, we have established the equivalences of (a), (b) and of (a), (d), (e), (f). Let us now prove the equivalences of (a), (c): If $\neg$ (a) then there is a strictly decreasing chain of ideals $\mathfrak{a}_0 \supset \mathfrak{a}_1 \supset \mathfrak{a}_2 \supset \ldots$ such that $\mathcal{A} := \{ \mathfrak{a}_0, \mathfrak{a}_1, \mathfrak{a}_2, \ldots \}$ is totally ordered under $\subseteq$, but infinite. That is we then also get $\neg$ (b).

Conversely suppose ¬ (c), that is there is an infinite set $\mathcal{A}$, that is totally ordered under $\subseteq$. We start by choosing any $\mathfrak{a}_0 \in \mathcal{A}$. Suppose we had already chosen $\mathfrak{a}_0 \subset \mathfrak{a}_1 \subset \ldots \subset \mathfrak{a}_n$ from $\mathcal{A}$, then we continue: First we choose any other $\mathfrak{a} \in \mathcal{A} \setminus \{ \mathfrak{a}_0, \mathfrak{a}_1, \ldots, \mathfrak{a}_n \}$, then we distinguish 3 cases: (1) If $\mathfrak{a}_n \subseteq \mathfrak{a}$ then we may simply take $\mathfrak{a}_{n+1} := \mathfrak{a}$ and have appended our chain, to $\mathfrak{a}_0 \subset \mathfrak{a}_1 \subset \ldots \subset \mathfrak{a}_n \subset \mathfrak{a}_{n+1}$. (2) If $\mathfrak{a} \subseteq \mathfrak{a}_0$ then we have $\mathfrak{a} \subset \mathfrak{a}_0 \subset \mathfrak{a}_1 \subset \ldots \subset \mathfrak{a}_n$. Thus all we have to to is shift the numbering of the $\mathfrak{a}_i$ to $\mathfrak{a}_{i+1}$ and call $\mathfrak{a}_0 := \mathfrak{a}$. (3) If neither (1) or (2), then let

$$k \;:=\; \max\{\, i \in 1 \ldots n \mid a_{i-1} \subseteq \mathfrak{a} \,\}$$

Then we get $\mathfrak{a}_0 \subset \ldots \subset \mathfrak{a}_{k-1} \subset \mathfrak{a} \subset \ldots \subset \mathfrak{a}_n$. Thus by renumbering these ideals (from k on) we are able to append our chain of ideals to $\mathfrak{a}_0 \subset \mathfrak{a}_1 \subset \ldots \subset \mathfrak{a}_n \subset \mathfrak{a}_{n+1}$ again. As we can do this indefinitely we conclude that $\ell(R) = \infty$, which is ¬ (d). But we already know that this is equivalent to ¬ (a). □

Proof of (3.120):
This proof is has been taken from the paper *Bilinear Maps on Artinian Modules* by *George M. Bergman* [2012]. It will require several steps:

- In a first step let us assume that b is non-degenerate, then we will eventually prove that L and M are of finite length: Let us denote the sub-modules of L that appear as orthogonal complements under b by

 $$\mathrm{Orc}(L) \;:=\; \left\{ Q^\perp \mid Q \;\leq_{\mathsf{m}}\; M \right\} \;\subseteq\; \mathrm{Subm}(L)$$

 Since L is an artinian module the partially ordered set $(\mathrm{Subm}(L), \subseteq)$ satisfies the DCC. And as $\mathrm{Orc}(L) \subseteq \mathrm{Subm}(L)$ is a subset, we in particular find that $(\mathrm{Orc}(L), \subseteq)$ satisfies the DCC. Likewise orc $(M) \subseteq \mathrm{Subm}(M)$ satisfies the DCC under the partial order $\subseteq$. But by (4.107.(i)) we have a Galois connection

 $$\begin{array}{rcl} \mathrm{Orc}(L) & \longleftrightarrow & \mathrm{Orc}(L) \\ P & \mapsto & P^\top \\ Q^\perp & \hookleftarrow & Q \end{array}$$

 As this correspondence is order-reversing, the DCC of $(\mathrm{Subm}(L), \subseteq)$ is turned into the ACC on $(\mathrm{Subm}(M), \subseteq)$ and vice versa. That is the partially ordered sets $(\mathrm{Subm}(L), \subseteq)$ and $(\mathrm{Subm}(M), \subseteq)$ satisfy *both* ACC and DCC. In particular we know by (0.26) that any chain in $(\mathrm{Subm}(L), \subseteq)$ is finite and can be refined to a maximal chain. Refining $M^\perp = 0 \subset L = 0^\perp$ we get a maximal ascending chain in $\mathrm{Orc}(L)$

 $$0 = P_0 \subset P_1 \subset \ldots \subset P_n = L$$

 Due to the one-to-one correspondence any $P_k \in \mathrm{Orc}(L)$ it is of the form $P_k = Q_k^\perp$ for some sub-module $Q_k \in \mathrm{Orc}(M)$ where we have $Q_k^\perp = P_k$ again. In particular the Q_k for a maximal descending chain in $\mathrm{Orc}(M)$, that is

 $$M = Q_0 \supset Q_1 \supset \ldots \supset Q_n = 0$$

 We will now prove that for any $k \in 1 \ldots n$ the following map is well-defined, bilinear and integral.

But let us take one step at a time

$$b_k \;:\; {}^{P_k}\!\Big/_{P_{k-1}} \times {}^{Q_{k-1}}\!\Big/_{Q_k} \to N \;:\; (u+P_{k-1},\, x+Q_k) \mapsto b(u,x)$$

First of all b_k is well-defined, if $(u+P_{k-1}, x+Q_k) = (v+P_{k-1}, y+Q_k)$ then $v-u \in P_{k-1} = Q_{k-1}^\perp$ and $y-x \in Q_k = P_k^\top$. That is $b(v-u,y) = 0$ for any $y \in Q_{k-1}$ and likewise $b(u,y-x) = 0$ for any $u \in P_k$. But then we can compute

$$\begin{aligned} b(v,y) &= b(v-u,y) + b(u,y) \;=\; b(u,y) \\ &= b(u,y-x) + b(u,x) \;=\; b(u,x) \end{aligned}$$

That is b_k is well-defined and it clearly inherits the bilinearity from b. We also claimed that b_k is *integral*, that is for any $\overline{u} = u + P_{k-1} \in P_k/P_{k-1}$ and any $\overline{x} = x + Q_k \in Q_{k-1}/Q_k$ we have the implication

$$b_k(\overline{u},\overline{x}) \;=\; 0 \quad\Longrightarrow\quad \overline{u} \;=\; 0 \;\text{ or }\; \overline{x} \;=\; 0$$

So let us start with any $u \in P_k = Q_k^\perp$ and $x \in Q_{k-1} = P_{k-1}^\top$. It is clear that for the sub-module $Ru \;\leq_{\mathsf{m}}\; L$ we have

$$\begin{aligned} \big(Ru\big)^\top &= \{\, x \in M \mid \forall\, a \in R : b(au,x) = 0 \,\} \\ &= \{\, x \in M \mid b(u,x) = 0 \,\} \end{aligned}$$

And as $u \in P_k = Q_k^\perp$ we have $Ru \;\subseteq\; Q_k^\perp$ which turns into $Q_k = (Q_k^\perp)^\top \;\subseteq\; (Ru)^\top$. Thus as $Q_k \;\subseteq\; (Ru)^\top$ and as $Q_k \;\subseteq\; Q_{k-1}$ we have

$$Q_k \;\subseteq\; Q_{k-1} \cap \big(Ru\big)^\top \;\subseteq\; Q_{k-1}$$

Thereby $Q_{k-1} \cap (Ru)^\top = P_{k-1}^\top \cap (Ru)^\top = (P_{k-1} + Ru)^\top$ from which we get $Q_{k-1} \cap (Ru)^\top \in \mathrm{Orc}(M)$. However we have chosen the chain $Q_0 \;\supset\; \ldots \;\supset\; Q_{k-1} \;\supset\; Q_k \;\supset\; \ldots \;\supset\; Q_n$ to be maximal in $\mathrm{Orc}(M)$. That is we either have $Q_k = Q_{k-1} \cap (Ru)^\top$ or $Q_{k-1} \cap (Ru)^\top = Q_{k-1}$. In the second case we see $Q_{k-1} \subseteq (Ru)^\top$ and thereby $Ru \subseteq ((Ru)^\top)^\perp \subseteq Q_{k-1}^\perp = Q_{k-1}$ which is $u \in Q_{k-1}$ and thereby $\overline{u} = 0$. So let us assume this is not the case, then necessarily

$$Q_k \;=\; Q_{k-1} \cap \big(Ru\big)^\top$$

If we have $b(u,x) = 0$ then $x \in (Ru)^\top$ and as also $x \in Q_{k-1}$ this implies $x \in Q_k$. But this is $\overline{x} = 0$. Thus we have proved that b_k also is integral. And by (4.107.(iv)) this implies

$$\overline{u} \;\neq\; 0 \;\text{ and }\; \overline{x} \;\neq\; 0 \quad\Longrightarrow\quad \mathrm{ann}(\overline{u}) \;=\; \mathrm{ann}(\overline{x}) \;\in\; \mathrm{Spec}(R)$$

Let $\mathfrak{p}_k := \mathrm{ann}(\overline{u}) = \mathrm{ann}(\overline{x})$ be the common annihilator ideal of all the non-zero elements $\overline{u} \in P_k/P_{k-1}$ and $\overline{x} \in Q_{k-1}/Q_k$ respectively. Then P_k/P_{k-1} (and Q_{k-1}/Q_k) are modules over the ring $R/\mathfrak{p}_k$ by virtue of the scalar multiplication $(a+\mathfrak{p}_k)\overline{u} := a\overline{u}$. But by (3.22) we have the following isomorphy of R-modules

$${}^{R}\!\Big/_{\mathfrak{p}_k} \quad\cong_{\mathsf{m}}\quad R\overline{u} \quad\leq_{\mathsf{m}}\quad {}^{L}\!\Big/_{P_{k-1}}$$

such that $R/\mathfrak{p}_k$ is isomorphic to a sub-module of the artinian module L/P_{k-1}. Hence $R/\mathfrak{p}_k$ is an artinian R-module itself, but this is the same as being an artinian ring (as in a commutative ring sub-modules are ideal). As $\mathfrak{p}_k$ is a prime ideal $R/\mathfrak{p}_k$ is an integral domain and hence a field, by (2.46.(i)). Thus P_k/P_{k-1} is a vector space over $R/\mathfrak{p}_k$. But P_k/P_{k-1} also is artinian, since $P_k \leq_{\mathsf{m}} L$ and L is artinian. But an artinian vector space has finite length, as we have seen in (3.113), resp. (3.119.(vii)). Now we can finally apply (3.118.(iii)) to find

$$\ell(L) \;=\; \sum_{k=1}^{n} \ell\left(P_k \Big/ P_{k-1}\right) \;<\; \infty$$

That is L has finite length, at last. And as the same reasoning holds true for the modules Q_{k-1}/Q_k we find (in complete analogy) that M has finite length, as well.

- For an arbitrary b note that by (4.107.(ii)) b induces a non-degenerate bilinear $\overline{b}$ map of the following form

$$\overline{b} \;:\; L\Big/_{M^\perp} \times M\Big/_{L^\top} \;\to\; N \;:\; \left(u+M^\perp, x+L^\top\right) \;\mapsto\; b(u,x)$$

And as L and M are artinian, so are the residue modules $L/M^\perp$ and $M/L^\top$. Then by the item above we find that $L/M^\perp$ and $M/L^\top$ are of finite length, which was one of the claims.

- As special case of a bilinear map is $t : L \times M \to L \otimes M$ given by $t(u,x) := u \otimes x$. Though it is of no importance to us let us note, that in this case we have $L^\top = \{\, x \in M \mid \forall\, u \in L : u \otimes x = 0 \,\}$, again

$$\overline{t} \;:\; L\Big/_{M^\perp} \times M\Big/_{L^\top} \;\to\; L \otimes M \;:\; \left(u+M^\perp, x+L^\top\right) \;\mapsto\; u \otimes x$$

By the universal property of the tensor product this bilinear map $\overline{t}$ now induces an R-linear map of the following form

$$L\Big/_{M^\perp} \otimes M\Big/_{L^\top} \;\to\; L \otimes M \;:\; \left(u+M^\perp\right) \otimes \left(x+L^\top\right) \;\mapsto\; u \otimes x$$

This map is an isomorphism however: If we denote the canonical projections onto the residue modules by $\varrho_L : L \twoheadrightarrow L/M^\perp : u \mapsto u+M^\perp$ and likewise $\varrho_M : M \twoheadrightarrow M/L^\top : x \mapsto x+L^\top$ then it is clear that $\varrho_L \otimes \varrho_M$ is the inverse map, as it is given to be $(\varrho_L \otimes \varrho_M)(u \otimes x) = \varrho_L(u) \otimes \varrho_M(x) = (u+M^\perp) \otimes (x+L^\top)$. In particular we have the isomorphy of

$$L\Big/_{M^\perp} \otimes M\Big/_{L^\top} \quad \cong_{\mathsf{m}} \quad L \otimes M$$

But in the item above we have proved that both $L/M^\perp$ and $M/L^\top$ are modules of finite length. And hence $L \otimes M$ is a module of finite length, too as by (3.155.(iii)) we have

$$\begin{aligned} \ell(L \otimes M) \;&=\; \ell\left(L\Big/_{M^\perp} \otimes M\Big/_{L^\top}\right) \\ &\leq\; \ell\left(L\Big/_{M^\perp}\right) + \ell\left(M\Big/_{L^\top}\right) \;<\; \infty \end{aligned}$$

□

Proof of (4.70):

(i) For any α and $\beta \in \mathrm{Asc}(r,n)$ let us denote the following map of the form $D_{\alpha,\beta} : \mathrm{mat}_n(R) = (R^n)^n \to R$, defined by

$$D_{\alpha,\beta}(A) \;:=\; \det\big(A[\alpha \mid \beta]\big) \cdot \det\big(A[\widehat{\alpha} \mid \widehat{\beta}]\big)$$

In a first step we will show that $D_{\alpha,\beta}$ is multi-linear. However we will do this for the first column of A only, as the other columns are just more notational fuzz. That is for any $a \in R$ and any $a_1, a_2, \ldots a_n \in R$ and any $b_1 \in R^n$ we need to show the properties

$$\begin{aligned} D_{\alpha,\beta}(a\,a_1, a_2, \ldots, a_n) &= a\,D_{\alpha,\beta}(a_1, a_2, \ldots, a_n) \\ D_{\alpha,\beta}(a_1 + b_1, a_2, \ldots, a_n) &= D_{\alpha,\beta}(a_1, a_2, \ldots, a_n) + \\ & \quad D_{\alpha,\beta}(b_1, a_2, \ldots, a_n) \end{aligned}$$

To further complicate things we denote $x' := (x_{\alpha(1)}, \ldots, x_{\alpha(r)}$ for any $x = (x_1, x_2, \ldots, x_n) \in R^n$. The scalar multiplicativity is quite obvious: If $1 \in S(\beta)$ then aa'_1 appears as the first column of $A[\alpha \mid \beta]$ and as the determinant is multi-linear we call pull the a in front. That is

$$\det\big((aa_1\, a_2\, \ldots\, a_n)[\alpha \mid \beta]\big) \;=\; a\det\big((a_1\, a_2\, \ldots\, a_n)[\alpha \mid \beta]\big)$$

And in this case $1 \in S(\beta)$ we also get $1 \notin S(\widehat{\beta})$ such that first column of A is scratched in $A[\widehat{\alpha} \mid \widehat{\beta}]$ and with it a. Therefore we then get

$$\det\big((aa_1\, a_2\, \ldots\, a_n)[\widehat{\alpha} \mid \widehat{\beta}]\big) \;=\; \det\big((a_1\, a_2\, \ldots\, a_n)[\widehat{\alpha} \mid \widehat{\beta}]\big)$$

If $1 \notin S(\beta)$ then $1 \in S(\widehat{\beta})$ so in any case the first column of A is scratched from one matrix but not from the other. So in both cases we find the first equation, needed:

$$D_{\alpha,\beta}(a\,a_1, a_2, \ldots, a_n) \;=\; a\,D_{\alpha,\beta}(a_1, a_2, \ldots, a_n)$$

Next we need to verify the additivity of $D_{\alpha,\beta}$ - to do this we need to introduce some matrices: First of all $A := (a_1\, a_2\, \ldots\, a_n)$ then $B_0 := (b_1\, 0\, \ldots\, 0)$ and lastly $B := (b_1\, a_2\, \ldots\, a_n)$. Using these we need to verify (compare this to the second equation above)

$$D_{\alpha,\beta}(A + B_0) \;=\; D_{\alpha,\beta}(A) + D_{\alpha,\beta}(B)$$

Again we need to distinguish two cases, beginning with $1 \in S(\beta)$. In this case $(A + B_0)[\alpha \mid \beta]$ contains $a'_1 + b'_1$ as the first column and as the determinant still is multi-linear we can pull out that sum:

$$\det\big((A + B_0)\,[\alpha \mid \beta]\,\big) \;=\; \det\big(A\,[\alpha \mid \beta]\,\big) + \det\big(B\,[\alpha \mid \beta]\,\big)$$

Note that in case $1 \in S(\beta)$ we have $1 \notin S(\widehat{\beta})$ again such that the first column of $A + B_0$ is scratched in $(A + B_0)[\widehat{\alpha} \mid \widehat{\beta}]$ entirely. Thus B_0 does not affect the result at all. And as A and B only differ in the first column, we also have $A[\widehat{\alpha} \mid \widehat{\beta}] = B[\widehat{\alpha} \mid \widehat{\beta}]$ such that

$$\det\Big((A + B_0)\,\Big[\widehat{\alpha} \mid \widehat{\beta}\Big]\Big) \;=\; \det\Big(A\,\Big[\widehat{\alpha} \mid \widehat{\beta}\Big]\Big) \;=\; \det\Big(B\,\Big[\widehat{\alpha} \mid \widehat{\beta}\Big]\Big)$$

If we combine these two equations and use the law of distibutivity we find the second equation

needed (in case $1 \in S(\beta)$)

$$\begin{aligned}
& D_{\alpha,\beta}(A + B_0) \\
= \;& \det\left((A + B_0)\,[\alpha \mid \beta]\right) \cdot \det\left((A + B_0)\left[\widehat{\alpha} \mid \widehat{\beta}\right]\right) \\
= \;& \left(\det\left(A\,[\alpha \mid \beta]\right) + \det\left(B\,[\alpha \mid \beta]\right)\right) \cdot \det\left(A\left[\widehat{\alpha} \mid \widehat{\beta}\right]\right) \\
= \;& D_{\alpha,\beta}(A) + \det\left(B\,[\alpha \mid \beta]\right) \cdot \det\left(A\left[\widehat{\alpha} \mid \widehat{\beta}\right]\right) \\
= \;& D_{\alpha,\beta}(A) + \det\left(B\,[\alpha \mid \beta]\right) \cdot \det\left(B\left[\widehat{\alpha} \mid \widehat{\beta}\right]\right) \\
= \;& D_{\alpha,\beta}(A) + D_{\alpha,\beta}(B)
\end{aligned}$$

If $1 \notin S(\beta)$ then $1 \in S(\widehat{\beta})$ so in any case the first column of $A + B_0$ is scratched from the first matrix but not from the second. In complete analogy to the above we arrive at

$$D_{\alpha,\beta}(A + B_0) \;=\; D_{\alpha,\beta}(A) + D_{\alpha,\beta}(B)$$

Altogether for any α, $\beta \in \mathrm{Asc}(r,n)$ the map $D_{\alpha,\beta}$ is multi-linear. Hence any R-linear combination of these maps is multi-linear, such as

$$D_\alpha(A) \;:=\; \sum_{\beta \in \mathrm{Asc}(r,n)} (-1)^{|\alpha|+|\beta|} D_{\alpha,\beta}(A)$$

Note that $D_\alpha(A)$ is precisely the expression of which we need to show that $D_\alpha(A) = \det(A)$. In a next step we will prove that D_α is alternating: That is whenever A has two equal columns, such as $a_p = a_q$ for some $p < q \in 1 \ldots n$ then we need $D_\alpha(A) = 0$. If both p and $q \in S(\beta)$ then $A[\alpha \mid \beta]$ contains a'_p and a'_q which are equal and hence $\det(A[\alpha \mid \beta]) = 0$. Hence all the summands of D_α in which $\{\, p, q \,\} \subseteq S(\beta)$ vanish. The same is true if $\{\, p, q \,\} \subseteq S(\widehat{\beta})$ that is if $p \notin S(\beta)$ and $q \notin S(\beta)$. Thus we may split D_α into the distinct sums

$$\begin{aligned}
D_\alpha(A) \;=\; & \sum_{p \in S(\beta),\, q \notin S(\beta)} (-1)^{|\alpha|+|\beta|} D_{\alpha,\beta}(A) + \\
& \sum_{p \notin S(\beta),\, q \in S(\beta)} (-1)^{|\alpha|+|\beta|} D_{\alpha,\beta}(A)
\end{aligned}$$

That is these two distinct sums run over the following subsets of $\mathrm{Asc}(r,n)$

$$\begin{aligned}
P \;&:=\; \{\, \beta \in \mathrm{Asc}(r,n) \mid p \in S(\beta),\; q \notin S(\beta) \,\} \\
Q \;&:=\; \{\, \beta \in \mathrm{Asc}(r,n) \mid p \notin S(\beta),\; q \in S(\beta) \,\}
\end{aligned}$$

If $\beta \in P$ then let us define $\beta' \in \mathrm{Asc}(r,n)$ such that p is replaced by q. That is β' is the uniquely determined ascending of indexes chain with

$$S(\beta') \;=\; (S(\beta) \setminus \{\, p \,\}) \cup \{\, q \,\}$$

Note that $\beta \mapsto \beta'$ is a bijection from P to Q, as the inverse map is given by replacing q by p. Also

it is clear, that $|\beta'| = |\beta| - p + q$, i.e.

$$|\beta'| - |\beta| \;=\; q - p$$

Now what does β' look like? Let $i, j \in 1 \dots n$ such that $p = \beta(i)$ and $q = \beta'(j)$. Then we see that β' with $d := j - i \geq 1$ is precisely the following chain of indexes (in ascending order)

$$\begin{array}{ccc}
\beta'(1) & = & \beta(1) \\
\vdots & & \vdots \\
\beta'(i-1) & = & \beta(i-1) \\
\hline
 & & \beta(i) = p \\
\beta'(i) & = & \beta(i+1) \\
\vdots & & \vdots \\
\beta'(i+d-1) & = & \beta(i+d) \\
\beta'(i+d) = q & & \\
\hline
\beta'(i+d+1) & = & \beta(i+d+1) \\
\vdots & & \vdots \\
\beta'(r) & = & \beta(r)
\end{array}$$

That is: The middle section of β' is a shifted version of the middle section of β and hence we can decompose $A[\alpha \mid \beta]$ into three blocks

$$\begin{aligned}
A'_L &:= \begin{pmatrix} | & & | \\ a'_{\beta(1)} & \dots & a'_{\beta(i-1)} \\ | & & | \end{pmatrix} \\
A'_S &:= \begin{pmatrix} | & & | \\ a'_{\beta(i+1)} & \dots & a'_{\beta(i+d)} \\ | & & | \end{pmatrix} \\
A'_R &:= \begin{pmatrix} | & & | \\ a'_{\beta(i+d+1)} & \dots & a'_{\beta(r)} \\ | & & | \end{pmatrix}
\end{aligned}$$

That is $A[\alpha \mid \beta] = (A'_L\, a'_p\, A'_S\, A'_R)$ (recall that the prime denotes the scratching of rows due to α) and likewise $A[\alpha \mid \beta'] = (A'_L\, A'_S\, a'_q\, A'_R)$. But as $a'_p = a'_q$ we see that we get $A[\alpha \mid \beta']$ by permuting the columns of $A[\alpha \mid \beta]$ with the cycle ζ^{-1} where $\zeta = (i\; i+1\; \dots\; i+d)$ and hence

$$A[\alpha \mid \beta'] \;=\; A[\alpha \mid \beta]\, P_\zeta^{-1}$$

As $\zeta \in S_r$ is a cycle of length $d+1$ we have $\operatorname{sgn}(\zeta) = d$ and hence $\det(P_\zeta^{-1}) = \operatorname{sgn}(\zeta)^{-1} = (-1)^{-d} = (-1)^d$. Altogether

$$\det\left(A[\alpha \mid \beta']\right) \;=\; (-1)^d \det\left(A[\alpha \mid \beta]\right)$$

Let us summarize: Since we get to β' by shifting $d+1$ elements of β the determinant of $A[\alpha \mid \beta']$

gains the factor $(-1)^d$. The same consideration applies when we compare $\widehat{\beta}'$ to $\widehat{\beta}$. As $p \in S(\beta)$ we have $p \notin S(\beta')$ and then again $p \in S(\widehat{\beta}')$. For the same reason $q \notin S(\widehat{\beta}')$. Only the indexes of $\widehat{\beta}$ from p to q are shifted. But how many are there? First of all there are $q-p+1$ numbers in between, but of these d belonged to β (including p). Thus we have to shift $q-p-d$ indexes to turn $\widehat{\beta}$ into $\widehat{\beta}'$ and therefore

$$\det\left(A[\widehat{\alpha} \mid \widehat{\beta}']\right) \;=\; (-1)^{q-p-d-1} \det\left(A[\widehat{\alpha} \mid \widehat{\beta}]\right)$$

Altogether

$$\begin{aligned} D_{\alpha,\beta'}(A) &= \det\left(A[\alpha \mid \beta']\right) \cdot \det\left(A[\widehat{\alpha} \mid \widehat{\beta}']\right) \\ &= (-1)^d \det\left(A[\alpha \mid \beta]\right) \cdot (-1)^{q-p-d-1} \det\left(A[\widehat{\alpha} \mid \widehat{\beta}]\right) \\ &= (-1)^{q-p-1} \det\left(A[\alpha \mid \beta]\right) \cdot \det\left(A[\widehat{\alpha} \mid \widehat{\beta}]\right) \\ &= -(-1)^{q-p} D_{\alpha,\beta}(A) \end{aligned}$$

That is every $\beta \in P$ has a partner $\beta' \in Q$ such that the respective summands in D_α cancel each other. Formally we may compute

$$\begin{aligned} & \sum_{\beta \in Q} (-1)^{|\alpha|+|\beta|} D_{\alpha,\beta}(A) \\ = \; & \sum_{\beta \in P} (-1)^{|\alpha|+|\beta'|} D_{\alpha,\beta'}(A) \\ = \; & -\sum_{\beta \in P} (-1)^{|\alpha|+|\beta|-p+q} (-1)^{q-p} D_{\alpha,\beta}(A) \\ = \; & -\sum_{\beta \in P} (-1)^{|\alpha|+|\beta|} D_{\alpha,\beta}(A) \end{aligned}$$

In a final step we will prove $D_\alpha(\mathbb{1}_n) = 1$. To do this we will first show $\det(\mathbb{1}_n[\alpha \mid \beta]) = \delta_{\alpha,\beta}$. By the definition of the determinant we can evaluate this explicitly

$$\begin{aligned} \det(\mathbb{1}_n[\alpha \mid \beta]) &= \sum_{\sigma \in S_r} \operatorname{sgn}(\sigma) \prod_{i=1}^{r} \operatorname{ent}_{i,\sigma(i)}(\mathbb{1}_n[\alpha \mid \beta]) \\ &= \sum_{\sigma \in S_r} \operatorname{sgn}(\sigma) \prod_{i=1}^{r} \delta_{\alpha(i),\beta\sigma(i)} \\ &= \sum_{\sigma \in S_r} \operatorname{sgn}(\sigma) \begin{cases} 1 \text{ if } \alpha = \beta\sigma \\ 0 \text{ if } \alpha \neq \beta\sigma \end{cases} \end{aligned}$$

However if $\alpha = \beta\sigma$ then in particular $S(\alpha) = S(\beta)$ and hence $\alpha = \beta$. That is we have $\det(\mathbb{1}_n[\alpha \mid \beta]) = 0$ whenever $\alpha \neq \beta$. In case $\alpha = \beta$ we have $\alpha = \beta\sigma$ if and only if $\sigma = \mathbb{1}$ which features $\operatorname{sgn}(\mathbb{1}) = 1$. Thus in case $\alpha = \beta$ we have $\det(\mathbb{1}_n[\alpha \mid \beta]) = 1$. In this case we also have $\widehat{\alpha} = \widehat{\beta}$ such that

$$\begin{gathered} D_{\alpha,\beta}(\mathbb{1}_n) \;=\; \delta_{\alpha,\beta} \\ \Longrightarrow \quad D_\alpha(\mathbb{1}_n) \;=\; \sum_{\beta \in \operatorname{Asc}(r,n)} (-1)^{|\alpha|+|\beta|} \delta_{\alpha,\beta} \;=\; (-1)^{2|\alpha|} \;=\; 1 \end{gathered}$$

In the three steps above we have *finally* shown, that D_α is an alternating, multi-linear map, so by lemma (4.55.(iv)) we now find

$$D_\alpha(A) \;=\; D_\alpha(\mathbb{1}_n)\cdot\det(A) \;=\; \det(A)$$

Thus we have proved the first formula in the Laplace expansion theorem. But as $A^*[\alpha \mid \beta] = A[\beta \mid \alpha]^*$ (4.83.(i)) and the determinant is invariant under transposition (4.55.(i)) we find $D_{\alpha,\beta}(A^*) = D_{\beta,\alpha}(A)$. Thus the second formula in the Laplace expansion theorem follows by applying the first formula to the transpose matrix A^*.

(ii) Now consider the product matrix $C = AB\mathrm{mat}_{k,n}(R)$, that is the (i,j)-th entry of C is $c_{i,j} = \langle \mathrm{row}_i(A), \mathrm{col}_j(B)\rangle$. Then for any $p, q \in 1\ldots r$ the (p,q)-th entry of $C[\alpha,\gamma]$ is

$$\begin{aligned}\mathrm{ent}_{p,q}(C[\alpha,\gamma]) &= \mathrm{ent}_{\alpha(p),\gamma(q)}(C)\\ &= \langle \mathrm{row}_{\alpha(p)}(A), \mathrm{col}_{\gamma(q)}(B)\rangle\\ &= \sum_{\beta=1}^{m} a_{\alpha(p),\beta}\, b_{\beta,\gamma(q)}\end{aligned}$$

We now evaluate the determinant of $C[\alpha,\gamma]$ explicitly, using nothing but the definition of the determinant, which is

$$\begin{aligned}&\det(C[\alpha,\gamma])\\ =\;& \sum_{\sigma\in S_r}\mathrm{sgn}(\sigma)\prod_{p=1}^{r}\mathrm{ent}_{p,\sigma(p)}(C[\alpha,\gamma])\\ =\;& \sum_{\sigma\in S_r}\mathrm{sgn}(\sigma)\prod_{p=1}^{r}\left(\sum_{\beta=1}^{m} a_{\alpha(p),\beta}\, b_{\beta,\gamma\sigma(p)}\right)\\ =\;& \sum_{\sigma\in S_r}\mathrm{sgn}(\sigma)\sum_{\beta(1)=1}^{m}\cdots\sum_{\beta(r)=1}^{m}\prod_{p=1}^{r} a_{\alpha(p),\beta(p)}\, b_{\beta(p),\gamma\sigma(p)}\\ =\;& \sum_{\beta\in(1\ldots m)^r}\sum_{\sigma\in S_r}\mathrm{sgn}(\sigma)\prod_{p=1}^{r} a_{\alpha(p),\beta(p)}\, b_{\beta(p),\gamma\sigma(p)}\\ =\;& \sum_{\beta\in(1\ldots m)^r}\prod_{p=1}^{r} a_{\alpha(p),\beta(p)}\sum_{\sigma\in S_r}\mathrm{sgn}(\sigma)\prod_{p=1}^{r} b_{\beta(p),\gamma\sigma(p)}\\ =\;& \sum_{\beta\in(1\ldots m)^r}\prod_{p=1}^{r} a_{\alpha(p),\beta(p)}\det\begin{pmatrix} b_{\beta(1),\gamma\sigma(1)} & \cdots & b_{\beta(1),\gamma\sigma(r)}\\ \vdots & \ddots & \vdots\\ b_{\beta(r),\gamma\sigma(1)} & \cdots & b_{\beta(r),\gamma\sigma(r)}\end{pmatrix}\\ =\;& \sum_{\beta\in(1\ldots m)^r}\prod_{p=1}^{r} a_{\alpha(p),\beta(p)}\det\big(B[\beta \mid \gamma]\big)\end{aligned}$$

If $\beta(p) = \beta(q)$ for some $p \neq q \in 1\ldots r$ then the p-th and q-th rows of the matrix $B[\beta \mid \gamma]$ are the same and hence its determinant vanishes. Thus this sum breaks down to the terms in which $\beta : 1\ldots r \hookrightarrow 1\ldots m$ is injective. There is an equivalence relation on the set of injections from $1 \to r$ to $1\ldots m$ however, by letting $\beta \sim \beta'$ if and only if $\beta(1\ldots r) = \beta'(1\ldots r)$. Every equivalence

class $[\beta]$ has a uniquely determined representative $\beta \in \mathrm{Asc}(r,m)$ and the class then is

$$[\beta] \;=\; \{\, \beta\varrho \mid \varrho \in S_r \,\}$$

Thus we may split the sum over all (injective) $\beta \in (1\ldots m)^r$ into a sum over $\beta \in \mathrm{Asc}(r,m)$ and a sum over all $\varrho \in S_r$

$$\det(C[\alpha,\gamma]) \;=\; \sum_{\beta\in\mathrm{Asc}(r,m)} \sum_{\varrho\in S_r} \prod_{p=1}^{r} a_{\alpha(p),\beta\varrho(p)}\, \det\big(B[\beta\varrho \mid \gamma]\big)$$

Now we see that for any fixed $\beta \in \mathrm{Asc}(r,m)$ the matrices in the above term are just different versions of the same matrix subjected to a permutation of rows $B[\beta\varrho \mid \gamma] = P_\varrho\, B[\beta \mid \gamma]$ In particular their determinants are just $\mathrm{sgn}(\varrho)$ times the determinant of the original matrix. Using this the determinant of $C[\alpha,\gamma]$ can finally be written in the desired form

$$\begin{aligned}
\det(C[\alpha,\gamma]) \;&=\; \sum_{\beta\in\mathrm{Asc}(r,m)} \sum_{\varrho\in S_r} \prod_{p=1}^{r} a_{\alpha(p),\beta\varrho(p)} \mathrm{sgn}(\varrho)\, \det\big(B[\beta \mid \gamma]\big) \\
&=\; \sum_{\beta\in\mathrm{Asc}(r,m)} \det\big(B[\beta \mid \gamma]\big) \sum_{\varrho\in S_r} \mathrm{sgn}(\varrho) \prod_{p=1}^{r} a_{\alpha(p),\beta\varrho(p)} \\
&=\; \sum_{\beta\in\mathrm{Asc}(r,m)} \det\big(B[\beta \mid \gamma]\big)\, \det\big(A[\alpha \mid \beta]\big)
\end{aligned}$$

□

Proof of (4.72):

(i) As the column rank of A has been defined, as the maximal number of linearly independent columns of A it is clear that c-rank$(A) \le n$. For any $j \in 1\ldots n$ let us now abbreviate $c_j := \mathrm{col}_j(A) \in R^m$ the j-th column of A. As $R^m = \mathrm{Lh}\{\, e_1, e_2, \ldots, e_m \,\}$ is generated by m elements lemma (3.99.(i)) tells us, that - whenever $J \subseteq 1\ldots n$ with $\#J \ge m+1$ - the set $\{\, c_j \mid j \in J \,\}$ is linearly dependent. In particular the number of linearly independent columns c_j cannot exceed m, that is c-rank$A \le m$, as well.

For the same property of the row-rank just consider the transpose matrix A^*. As this satisfies r-rank(A) = c-rank$(A^*) \le \min\{\, m,n \,\}$ the statement is already proved, as well.

The same reasoning can be used to prove c-rank$(A) \le$ i-rank(A): By definition of the vector-matrix multiplication we have $Ax = x_1c_1 + \cdots + x_nc_n \in R^m$ for any $x \in R^n$ and thereby $\mathrm{im}(A) = \mathrm{Lh}\{\, c_1, \ldots, c_n \,\}$. In particular $c_J := \{\, c_j \mid j \in J \,\} \subseteq \mathrm{im}(A)$ for any $J \subseteq 1\ldots n$. Now pick up a generating set $\{\, x_1, \ldots, x_r \,\} \subseteq \mathrm{im}(A)$ of $\mathrm{im}(A)$ such that $r = \mathrm{rank}(\mathrm{im}(A)) =$ i-rank(A). If $J \subseteq 1\ldots n$ such that c_J is linearly independent, then necessarily $\#J \le r$, by (3.99.(i)) again. And as c-rank$(A) = \#J$ for some $J \subseteq 1\ldots n$ this means c-rank$(A) \le r = \mathrm{rank}(\mathrm{im}(A)) =$ i-rank(A).

(i) **Remark:** In the proof of (i) we used the very intricate lemma (3.99.(i)) which in turn uses Hilbert's basis theorem and the theory of noetherian modules. In the case of a field R, this argument can be replaced by (3.66.(vii)) which likewise implies that $\#J \le \dim(R^m) = m$.

(ii) Let us abbreviate $B_j := \mathrm{col}_j(B)$ and suppose for some $J \subseteq 1\ldots n$ the vectors $\{\, B_j \mid j \in J \,\}$ are

linearly dependent. That is we have

$$\sum_{j\in J} a_i B_j \;=\; 0$$

for some $a_j \in R$ that are not all $= 0$. But since A is linear this already implies, that $\{\, AB_j \mid j \in J \,\}$ is linearly dependent as well, since

$$\sum_{j\in J} a_i AB_j \;=\; A\left(\sum_{j\in J} a_i B_j\right) \;=\; A(0) \;=\; 0$$

Negating the statement we find: If $\{\, AB_j \mid j \in J \,\}$ is linearly independent then $\{\, B_j \mid j \in J \,\}$ has already been linearly independent. Recall that the AB_1, AB_2 to AB_n are precisely the columns of AB. Hence

$$\text{c-rank}(AB) \;\leq\; \text{c-rank}(B)$$

Recall that $(AB)^* = B^*A^*$ since R is commutative. Such that, going to transpose matrices, we find the following inequality from this

$$\text{r-rank}(AB) \;=\; \text{c-rank}(B^*A^*) \;\leq\; \text{c-rank}(A^*) \;=\; \text{r-rank}(A)$$

(iii) Let us abbreviate $A' := A[\alpha \mid \beta]$ and $q := \text{c-rank}(A')$. For ease of notation let us also assume that $\text{col}_1(A')$ to $\text{col}_q(A') \in R^m$ are linearly independent columns of A'. We now define the map $P_\alpha : R^m \to R^r$ by virtue of $P_\alpha(x) := x'$ where for $x = (x_1, \ldots, x_m) \in R^m$ we let $x' := (x_{\alpha(1)}, \ldots, x_{\alpha(r)}) \in R^r$. Then it is clear, that

$$\text{col}_j(A') \;=\; P_\alpha\left(\text{col}_{\beta(j)}(A)\right)$$

for any $j \in 1 \ldots s$. We will now prove that $\text{col}_{\beta(1)}(A)$ to $\text{col}_{\beta(q)}(A)$ are linearly independent. To do this let us assume there was some relation between these vectors

$$\sum_{j=1}^{q} a_j \,\text{col}_{\beta(j)}(A) \;=\; 0$$

As the projection P_α is R-linear this would also yield a relation between the vectors $\text{col}_1(A')$ to $\text{col}_q(A')$, since

$$\begin{aligned} 0 \;&=\; P_\alpha\left(\sum_{j=1}^{q} a_j \,\text{col}_{\beta(j)}(A)\right) \\ &=\; \sum_{j=1}^{q} a_j \, P_\alpha\left(\text{col}_{\beta(j)}(A)\right) \\ &=\; \sum_{j=1}^{q} a_j \,\text{col}_j(A') \end{aligned}$$

But since these are linearly independent by assumption, this means $a_j = 0$ for any $j \in 1 \ldots q$. But this is precisely the linear independence of the $\text{col}_{\beta(j)}(A)$. That is A contains at least q linearly

independent columns and hence we find

$$\text{c-rank}(A') \;=\; q \;<\; \text{c-rank}(A)$$

For the row-rank we simply take to the transpose matrix: Note that $A[\alpha \mid \beta]^* = A^*[\beta \mid \alpha]$ and use the inequality we have just shown for the column-rank

$$\begin{aligned}\text{r-rank}(A) \;&=\; \text{c-rank}(A^*) \;\geq\; \text{c-rank}(A^*[\beta \mid \alpha]) \\ &=\; \text{c-rank}(A[\alpha \mid \beta]^*) \;=\; \text{r-rank}(A[\alpha \mid \beta])\end{aligned}$$

(v) Define $\alpha \in \text{Asc}(r,m)$ by $\alpha(i) = i$ for any $i \in 1 \ldots r$ and consider the submatrix $A' := A[\alpha \mid \mu]$ of A. That is $a'_{i,i} = a_{\alpha(i),\mu(i)} = a_{i,\mu(i)} \neq 0$ and $a'_{i,j} = a_{\alpha(i),\mu(j)} = a_{i,\mu(j)}$. If now $j < i$, then $\mu(j) < \mu(i)$ such that the assumption on A then yields $a'_{i,j} = 0$. Altogether A' is a square, upper triangular matrix non-zero entries on the diagonal

$$A' \;=\; \begin{pmatrix} a_{1,\mu(1)} & a_{1,\mu(2)} & \cdots & a_{1,\mu(r)} \\ 0 & a_{2,\mu(2)} & \cdots & a_{2,\mu(r)} \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \ldots & 0 & a_{r,\mu(r)} \end{pmatrix}$$

We will now prove, that in this case $\text{r-rank}(A') = r$. That is we need to show that all the r rows of A' are linearly independent. Suppose

$$\sum_{i=1}^{r} a_i \,\text{row}_i(A') \;=\; 0$$

then we have to show that all the a_i are zero. We start with a_r and use induction down to a_1. Since the sum in R^r is zero, so are all its components, in particular

$$0 \;=\; \left[\sum_{i=1}^{r} a_i \,\text{row}_i(A')\right]_r \;=\; \sum_{i=1}^{r} a_i \,a'_{r,i} \;=\; a_r \,a'_{r,r}$$

In the last step we used that $a'_{r,i} = 0$ for any $i < r$. But we also have $a'_{r,r} \neq 0$ which means - since R is an integral domain - that $a_r = 0$. Now suppose we already had $a_r = a_{r-1} = \cdots = a_{k+1} = 0$. Then we want to show, that $a_k = 0$, as well. To do this compute

$$0 \;=\; \left[\sum_{i=1}^{r} a_i \,\text{row}_i(A')\right]_k \;=\; \sum_{i=1}^{r} a_i \left[\text{row}_i(A')\right]_k \;=\; \sum_{i=1}^{k} a_i \left[\text{row}_i(A')\right]_k$$

by induction hypothesis. As before $a'_{k,i} = 0$ for any $i < k$ such that this sum also boils down to a single term

$$0 \;=\; \sum_{i=1}^{k} a_i \left[\text{row}_i(A')\right]_k \;=\; \sum_{i=1}^{k} a_i \,a'_{k,i} \;=\; a_k \,a'_{k,k}$$

Again, as $a'_{k,k} \neq 0$ and R is an integral domain we conclude $a_k = 0$. Thus we find $a_i = 0$ for any $i \in 1 \ldots r$, which means that the rows of A' are linearly independent and therefore $\text{r-rank}(A') = r$.

In exactly the same way we can prove that c-rank$(A') = 0$, in this case we would start with $a_1 = 0$ and use induction up to $a_r = 0$. But as A' is a submatrix of A item (iii) tells us, that

$$\begin{aligned} \text{c-rank}(A) &\geq \text{c-rank}(A') = r \\ \text{r-rank}(A) &\geq \text{r-rank}(A') = r \end{aligned}$$

On the other hand the assumption on A includes $\text{row}_i(A) = 0$ for any $i > r$. That is in truth A is of the following form

$$A = \begin{pmatrix} \text{---} & \text{row}_1(A'') & \text{---} \\ & \vdots & \\ \text{---} & \text{row}_r(A'') & \text{---} \\ 0 & \dots & 0 \\ \vdots & & \vdots \\ 0 & \dots & 0 \end{pmatrix}$$

for some $A'' \in \text{mat}_{r,n}(R)$. As the zero-rows clearly at the bottom do neither contribute to the column-rank nor the row-rank of A we have c-rank$(A) =$ c-rank(A'') and also r-rank$(A) =$ r-rank(A''). It is clear that r-rank$(A'') \leq r$ such that

$$r = \text{r-rank}(A') \leq \text{r-rank}(A) = \text{r-rank}(A'') \leq r$$

and we finally get r-rank$(A) = r$. But by (i) we also have c-rank$(A'') \leq r$, such that the same argument holds true for the column-rank and we also find c-rank$(A) = r$ according to

$$r = \text{c-rank}(A') \leq \text{c-rank}(A) = \text{c-rank}(A'') \leq r$$

(vi) Let us first prove c-rank$(A) =$ free(M): To do this consider some set $J \subseteq 1 \dots n$ of indexes, such that $\{ c_j \mid j \in J \}$ is linearly independent, but for any $k \in 1 \dots n \setminus J$ the set $\{ c_j \mid j \in J \} \cup c_k$ is linearly dependent. Then $L := \{ c_j \mid j \in J \}$ and $X := \{ c_k \mid k \in 1 \dots n \setminus J \}$ satisfy the assumptions of corollary (3.102.(v)). Therefore we find

$$\text{c-rank}(A) = \#J = \text{free}(M) \leq \text{rank}(M) = \text{i-rank}(A)$$

The proof of r-rank$(A) =$ free(N) is just the same: In this case we pick up $I \subseteq 1 \dots m$ such that $L := \{ r_i \mid i \in I \}$ is linearly independent such that for any $k \in 1 \dots m \setminus I$ the set $L \cup \{ r_k \}$ is linearly dependent. Then (3.102.(v)) again implies

$$\text{r-rank}(A) = \#I = \text{free}(N)$$

(vi) It remains to prove that c-rank$(A) =$ r-rank(A). Let us abbreviate the j-th column (where $j \in 1 \dots n$) of A by $c_j := \text{col}_j(A) \in R^m$. If now $r = \text{c-rank}(A)$ then there is some $\beta \in \text{Asc}(r, n)$ such that

$$\left\{ c_{\beta(i)} \mid i \in 1 \dots r \right\} \subseteq R^m$$

is R-linearly independent. Let $E := \text{QUOT}(R)$ be the quotient field of R, then by (3.63) this set is

E-linearly independent as well. Thus it even is a basis of

$$U \;:=\; \mathrm{Lh}_E\{\, c_{\beta(i)} \mid i \in 1 \dots r \,\} \quad \leq_{\mathrm{v}} \quad E^m$$

By assumption any other c_k is R-linearly dependent on this set, that is for any $k \in 1 \dots n$ there are coefficients $t_{i,k} \in R$ such that

$$c_k \;=\; \sum_{i=1}^{r} t_{i,k}\, c_{\beta(i)}$$

We will later use the matrix of these coefficients $T := (t_{i,k}) \in \mathrm{mat}_{r,n}(R)$. In particular it is clear that U even is the entire column space of A

$$U \;=\; \mathrm{Lh}_E\{\, c_j \mid j \in 1 \dots n \,\} \quad \leq_{\mathrm{v}} \quad E^m$$

Let us define the submatrix $A' \in \mathrm{mat}_{m,r}(R)$ of A that is made of exactly these r linearly independent columns of A, that is

$$\begin{aligned} A' \;&:=\; \begin{pmatrix} | & | & & | \\ c_{\beta(1)} & c_{\beta(2)} & \dots & c_{\beta(r)} \\ | & | & & | \end{pmatrix} \\ &=\; \begin{pmatrix} a_{1,\beta(1)} & a_{1,\beta(2)} & \dots & a_{1,\beta(r)} \\ a_{2,\beta(1)} & a_{2,\beta(2)} & \dots & a_{2,\beta(r)} \\ \vdots & \vdots & & \vdots \\ a_{m,\beta(1)} & a_{m,\beta(2)} & \dots & a_{m,\beta(r)} \end{pmatrix} \end{aligned}$$

Looking at proposition (4.20) we see that $X = A$ and $Y = A'$ such that $A = A'T$. But on the other hand we can compute

$$A \;=\; A'T \;=\; \begin{pmatrix} \text{——} & T^*\mathrm{row}_1(A') & \text{——} \\ \text{——} & T^*\mathrm{row}_2(A') & \text{——} \\ & \vdots & \\ \text{——} & T^*\mathrm{row}_m(A') & \text{——} \end{pmatrix}$$

Thereby for any $p \in 1 \dots m$

$$\begin{aligned} T^*\mathrm{row}_p(A') \;&=\; \begin{pmatrix} t_{1,1} & \dots & t_{r,1} \\ \vdots & & \vdots \\ t_{1,n} & \dots & t_{r,n} \end{pmatrix} \begin{pmatrix} a_{p,\beta(1)} \\ \vdots \\ a_{p,\beta(r)} \end{pmatrix} \\ &=\; \begin{pmatrix} \sum_{i=1}^{r} t_{i,1} a_{p,\beta(i)} \\ \vdots \\ \sum_{i=1}^{r} t_{i,n} a_{p,\beta(i)} \end{pmatrix} \\ &=\; \sum_{i=1}^{r} a_{p,\beta(i)} \begin{pmatrix} t_{i,1} \\ \vdots \\ t_{i,n} \end{pmatrix} \end{aligned}$$

$$= \sum_{i=1}^{r} a_{p,\beta(i)}\, \mathrm{row}_i(T)$$

In particular we see that for any $p \in 1 \dots m$ the p-th row of A is a R-linear combination of the r rows of T

$$\mathrm{row}_p(A) \;=\; T^* \mathrm{row}_p(A') \;\in\; \mathrm{Lh}_E\{\, \mathrm{row}_i(T) \mid i \in 1 \dots r \,\}$$

Hereby the row space of T (as a subspace of E^n) is generated by r elements and hence is at most r-dimensional. Therefore there can be at most r E-linearly independent rows $\mathrm{row}_p(A)$ of A. But if any $r+1$ rows of A are E-linearly dependent by (3.63) again, they are R-linearly dependent already. And this finally means

$$\text{r-rank}(A) \;\leq\; r \;=\; \text{c-rank}(A)$$

Note that this inequality has been established for any matrix A of any size. Thus it also holds true for $B := A^*$. And with this we also find the converse inequality

$$\text{c-rank}(A) \;=\; \text{r-rank}(B) \;\leq\; \text{c-rank}(B) \;=\; \text{r-rank}(A)$$

(iv) As R is an integral domain and $\det(S) \neq 0$ corollary (4.65.(ii)) tells us that $\mathrm{kn}(S) = 0$. That is for any $x \in R^m$ we have $Sx = 0$ if and only if $x = 0$. On the other hand the columns of SA clearly are Sc_j

$$SA \;=\; \begin{pmatrix} | & | & & | \\ Sc_1 & Sc_2 & \dots & Sc_n \\ | & | & & | \end{pmatrix}$$

Thus if we regard some subset $J \subseteq 1 \dots n$ and $x_j \in R$, where $j \in J$ then for $x = \sum_j x_j c_j \in R^m$ we find the equivalence of

$$\sum_{j\in J} x_j c_j \;=\; 0 \quad\Longleftrightarrow\quad \sum_{j\in J} x_j S c_j \;=\; S\left(\sum_{j\in J} x_j c_j\right) \;=\; 0$$

Therefore $\{\, c_j \mid j \in J \,\}$ is linearly independent if and only if the set $\{\, Sc_j \mid j \in J \,\}$ is linearly independent. And as the Sc_j are the columns of SA this in particular means, that

$$\text{c-rank}(SA) \;=\; \text{c-rank}(A)$$

Note that this has been proved for any matrices A and S. Thus given A and T consider $B := A^*$ and $S := T^*$ then $AT = B^*S^* = (SB)^*$ and therefore we find

$$\text{r-rank}(AT) \;=\; \text{c-rank}(SB) \;=\; \text{c-rank}(B) \;=\; \text{r-rank}(A)$$

So far this has been proved without using that both ranks are equal, due to (v). If we also use that $\text{c-rank}(A) = \text{r-rank}(A)$ for any matrix A then we can complete the proof to full effect

$$\text{c-rank}(SAT) \;=\; \text{c-rank}(AT) \;=\; \text{r-rank}(AT)$$

$$\begin{aligned} &= \text{r-rank}(A) = \text{c-rank}(A) \\ \text{r-rank}(SAT) &= \text{r-rank}(SA) = \text{c-rank}(SA) \\ &= \text{c-rank}(A) = \text{r-rank}(A) \end{aligned}$$

(vii) In this statement R is assumed to be a PID. In particular we have c-rank(A) = r-rank(A), as this is true in any integral domain and c-rank$(A) \leq \min\{ m, n \}$ according to (i). It remains to prove c-rank(A) = i-rank(A) = rank(im(A)). So let $c_j := \text{col}_j(A)$ be the j-th column of A again (where $j \in 1 \ldots n$) and pick up a subset $J \in 1 \ldots n$ such that $\#J$ is maximal with the property that $\{ c_j \mid j \in J \}$ is linearly independent. That is $r := \#J =$ c-rank(A) and if we consider any $i \in 1 \ldots n \setminus J$, then there are some non-trivial $u_{i,j}$ and $v_i \in R$ such that

$$\sum_{j \in J} u_{i,j} c_j + v_i c_i = 0$$

As the $\{ c_j \mid j \in J \}$ are linearly independent this relation has to encompass c_i such that $v_i \neq 0$. Now define v the product of the v_i, where i runs along $i \notin J$ and let

$$C := \text{Lh}\{ c_j \mid j \in J \} \leq_{\mathtt{m}} R^m$$

Then $\{ c_j \mid j \in J \}$ is a basis of C, but as R is a PID and R^m is finitely generated and free, (3.104) tells us, that im(A) also is finitely generated and free. Also it is clear, that $C \subseteq$ im(A), as im$(A) = \text{Lh}\{ c_1, \ldots, c_n \}$. Hence we may pick up a basis $\{ x_1, \ldots, x_s \}$ of im(A). Recall

$$v_i c_i = -\sum_{j \in J} u_{i,j} c_j \in \text{Lh}\{ c_j \mid j \in J \} = C$$

$$v := \prod_{i \notin J} v_i \implies v c_i = \widehat{v_i} v_i c_i \in C$$

for any $i \in 1 \ldots n \setminus J$. And for $j \in J$ we have $c_j \in C$ by construction, such that $v c_i \in C$ is true for any $i \in 1 \ldots n$. But the image of A is generated by the columns of A, that is im$(A) = \text{Lh}\{ c_1, \ldots, c_n \}$ and in particular any x_k is of the form

$$x_k = \sum_{j=1}^{n} h_{j,k} c_j \implies v x_k = \sum_{j=1}^{n} h_{j,k} v c_j \in C$$

That is $\{ v x_1, \ldots, v x_s \} \subseteq C$. But as $v \neq 0$ and im(A) is free in particular torsion-free the set $\{ v x_1, \ldots, v x_s \}$ is linearly independent again: Suppose we had a relation on this set

$$0 = \sum_{k=1}^{s} a_k v x_k = v \sum_{k=1}^{s} a_k x_k \implies 0 = \sum_{k=1}^{s} a_k x_k$$

then this would yield a relation on the set $\{ x_1, \ldots, x_s \}$ itself. But as this is a basis this implies $a_1 = \cdots = a_s = 0$ such that $\{ v x_1, \ldots, v x_s \}$ is linearly independent, too. That is C contains the linearly independent set $\{ v x_1, \ldots, v x_s \}$, although it is an r-dimensional module, by construction.

Hence (3.104.(i)) implies $s \leq r$ and this has been (using (i) in the end)

$$\text{i-rank}(A) \;=\; \dim(\text{im}(A)) \;=\; s \;\leq\; r \;=\; \text{c-rank}(A) \;\leq\; \text{i-rank}(A)$$

(viii) In this statement R is assumed to be a skew field. We will prove the equality $\text{r-rank}(A) = \dim(N)$ only, as the proof of $\text{c-rank}(A) = \dim(M)$ is completely analogous. So let $p := \text{r-rank}(A)$ and $I \subseteq 1 \ldots m$ be one of those sets for which $\#I = p$ and r_I is R-linearly independent. If $p = m$, then $\{ r_1, r_2, \ldots, r_m \}$ is a basis of N and hence $\dim(N) = m = p$ is clear. Otherwise, since I is of maximal size we find that for any $k \in 1 \ldots m$ with $k \notin I$ the set $\{ r_i \mid i \in I \} \cup \{ r_k \}$ *is* linearly dependent. That is there are some $a_i \in R$ (not-all zero) such that

$$\sum_{i \in I} a_i r_i + a_k r_k \;=\; 0$$

If $a_k = 0$ then r_I already would be linearly dependent, which it is not. Hence we have $a_k \neq 0$ and since R is a skew-field this implies

$$r_k \;=\; \sum_{i \in I} \big(-a_k^{-1} a_i \big) r_i \;\in\; \text{Lh}(r_I)$$

And as this is true for any $k \notin I$ we find $N \subseteq \text{Lh}(r_I) \subseteq N$. So r_I generates N but also is linearly independent, therefore a basis of N. Hence

$$\text{r-rank}(A) \;=\; \#I \;=\; \#r_I \;=\; \dim(N)$$

Finally we have $\text{i-rank}(A) = \text{rank}(\text{im}(A)) = \text{rank}(M) = \dim(M)$, since R is a skew-field. This has been explained in remark (3.100).

(ix) The implication (b) $\Longrightarrow$ (a) is true for a general commutative ring and easy to see: Suppose there are some $a_1, a_2, \ldots, a_m \in R$ such that

$$\sum_{i=1}^{m} a_i \, x_i \;=\; 0$$

By (b) there is some $\alpha \in \text{Asc}(m, n)$ such that $\{ P_\alpha(x_1), \ldots, P_\alpha(x_m) \}$ is linearly independent. But as the projection P_α is R-linear we find

$$0 \;=\; P_\alpha \left(\sum_{i=1}^{m} a_i \, x_i \right) \;=\; \sum_{i=1}^{m} a_i \, P_\alpha(x_i)$$

The linear independence of the $P_\alpha(x_i)$ implies $a_1 = a_2 = \cdots = a_m = 0$ and hence the x_i are linearly independent themselves. Conversely let us define the matrix

$$A \;=\; \begin{pmatrix} | & | & & | \\ x_1 & x_2 & \ldots & x_m \\ | & | & & | \end{pmatrix} \;\in\; \text{mat}_{n,m}(R)$$

By assumption (a) we have $\text{c-rank}(A) = m$, but if R is an integral domain, then by (vi) we also

have r-rank(A) = c-rank$(A) = m$. That is there is some $\alpha \in \mathrm{Asc}(m,n)$ such that $\mathrm{row}_{\alpha(1)}(A)$ to $\mathrm{row}_{\alpha(m)}(A)$ are linearly independent. Thereby it is clear that

$$A' := \begin{pmatrix} \text{---} & \mathrm{row}_{\alpha(1)}(A) & \text{---} \\ & \vdots & \\ \text{---} & \mathrm{row}_{\alpha(m)}(A) & \text{---} \end{pmatrix} = \begin{pmatrix} | & & | \\ P_\alpha(x_1) & \dots & P_\alpha(x_m) \\ | & & | \end{pmatrix}$$

But since c-rank(A') = r-rank$(A') = m$ again, we find, that the $P_\alpha(x_i)$ are linearly independent. And this is precisely the claim of (b).

□

Proof of (4.79):
We will first prove the equivalences of (a), (b) and (c): If (a), that is c-rank$(A) = q \leq r$ then there is some $I \subseteq 1 \dots n$ with $\#I = q$ such that $\{ c_j \mid j \in J \}$ is linearly independent but for any $k \in 1 \dots n \setminus J$ the set $\{ c_j \mid j \in J \} \cup \{ c_k \}$ *is* linearly dependent. That is there are some a_j and $b \in F$ such that

$$\sum_{j \in J} a_j c_j + b c_k \;=\; 0$$

If $b = 0$ then we would also have $a_j = 0$ for any $j \in J$, as $\{ c_j \mid j \in J \}$ is linearly independent. But as c_k is linearly dependent we may assume otherwise. Now, since F is a field, this means:

$$c_k \;=\; \sum_{j \in J} (-a_j b^{-1}) c_j \;\in\; \mathrm{Lh}_F\{ c_j \mid j \in J \}$$

Of course any c_j for some $j \in J$ is contained in the linear hull Lh$\{ c_j \mid j \in J \}$, as well. And this remains true if we expand I to size r by adding random elements of $1 \dots n$. So we have arrived at (b).
Now assume (b), for ease of notation we may assume $J = 1 \dots r$, then by assumption any c_k can be expressed as a linear combination of c_1 to c_r

$$c_k \;=\; \sum_{i=1}^{r} a_{i,k} c_i$$

Thus if we define the matrix $C \in \mathrm{mat}_{m,r}(F)$ to have the columns $\mathrm{col}_i(C) = c_i$ and the matrix $R \in \mathrm{mat}_{r,n}(F)$ then proposition (4.20) tells us, that truly $A = C\,R$. So we have deduced (c).
For the first part it remains to show that (c) implies (a). But this is easy to see, using (4.72.(ii)) and (4.72.(i)) as these yield

$$\text{c-rank}(A) \;=\; \text{c-rank}(C\,R) \;\leq\; \text{c-rank}(R) \;\leq\; \min\{ r, n \} \;\leq\; r$$

In the next part we will prove the equivalence of (e), (d) and (c): Starting with (e) we have c-rank(A^*) = r-rank$(A) \leq r$ and hence (b) holds true for the columns of A^*. But as the columns of A^* are just the rows of A we find statement (d). Likewise (d) implies the decomposition $A^* = R^*\,C^*$ for some matrices $R^* \in \mathrm{mat}_{n,r}(F)$ and $C^* \in \mathrm{mat}_{r,m}(F)$. But transposing this equation we find (c) $A = C\,R$. And (c) in turn implies (e) by virtue of (4.72.(ii)) and (4.72.(i)) again:

$$\text{r-rank}(A) \;=\; \text{r-rank}(C\,R) \;\leq\; \text{r-rank}(C) \;\leq\; \min\{ m, r \} \;\leq\; r$$

In the third and final step we need to argue, that c-rank(A) equals r, where r is the minimal number such that there are some $C \in \mathrm{mat}_{m,r}(F)$ and $R \in \mathrm{mat}_{r,n}(F)$ such that $A = C\,R$. By (a) this already implies c-rank$(A) \leq r$. Suppose c-rank$(A) < r$, then by (c) there would be a decomposition $A = C'\,R'$ of smaller size. But as r was assumed to be minimal, this cannot be and hence c-rank$(A) = r$. Precisely the same reasoning also yields r-rank$(A) = r$ and hence r-rank(A) = c-rank(A), as well. □
The proof of (4.83.(vii)) requires substantial effort. We hence chose to export a part of the argument here. Due to its technicak natrue we do not deem it worthy to be presented in the first part of the book, though.

(15.1) Proposition: (viz. 926)
Let $(R, +, \cdot)$ be a commutative ring and $A \in \mathrm{mat}_{m,n}(R)$ where $n \leq m$. For $\alpha \in \mathrm{Asc}(n,m)$ let us denote the submatrix $A_\alpha = A[\alpha \mid \mathbb{1}] \in \mathrm{mat}_n(R)$ of A. Then all the coefficients of the product $AA^*_\alpha \in \mathrm{mat}_n(R)$ are taken from

$$\mathrm{ent}_{i,j}(AA^*_\alpha) \;\in \bigcup_{m \in \mathrm{Minor}_n(A)} \{\, m, -m, 0 \,\} \;\subseteq\; \mathfrak{f}_n(A)$$

Proof of (15.1):
Let us denote $A = (a_{i,k})$ and $A^*_\alpha = (a^\#_{j,k})$ where $i \in 1 \ldots m$ and $j, k \in 1 \ldots n$. Then by definition of the matrix multiplication we have

$$\begin{aligned}
\mathrm{ent}_{i,k}(AA^*_\alpha) &= \sum_{j=1}^{n} a_{i,j}\, a^\#_{j,k} \\
&= \sum_{j=1}^{n} a_{i,j}\, (-1)^{j+k} \det\big(A\,[\alpha \mid \mathbb{1}]_{k,j}\big) \\
&= \sum_{j=1}^{n} (-1)^{j+k} a_{i,j} \det\big(A\,[\alpha \mid \mathbb{1}]_{k,j}\big)
\end{aligned}$$

By the Laplace expansion theorem (4.55.(v)) this is precisely the expansion of the matrix B along the i-th row, where B is gained from A_α by replacing the k-th row of A_α by the j-th row of A. That is

$$\mathrm{ent}_{i,k}(AA^*_\alpha) \;=\; \det \begin{pmatrix}
\text{—— } \mathrm{row}_{\alpha(1)}(A) \text{ ——} \\
\vdots \\
\text{—— } \mathrm{row}_{\alpha(k-1)}(A) \text{ ——} \\
\text{—— } \mathrm{row}_{j}(A) \text{ ——} \\
\text{—— } \mathrm{row}_{\alpha(k+1)}(A) \text{ ——} \\
\vdots \\
\text{—— } \mathrm{row}_{\alpha(n)}(A) \text{ ——}
\end{pmatrix}$$

If $j \in \{\, \alpha(1), \ldots, \alpha(k-1), \alpha(k+1), \ldots, \alpha(n) \,\}$ then $\mathrm{row}_j(A)$ appears twice in this matrix and hence the determinant is 0 in this case. If not we can permute the rows of this matrix such that the order of the rows matches the order of the rows of A. But as permuting the rows only changes the sign of the determinant, we find that $\mathrm{ent}_{i,k}(AA^*_\alpha) = \pm m$ for some $m \in \mathrm{Minor}_n(A)$. □

Proof of (4.83):

(i) As usual let A have the entries $A = (a_{i,j})$ and fix some $i \in 1 \ldots r$ and $j \in 1 \ldots s$. Then we take a

look at the (j,i)-th entry of the two matrixes in question:

$$\mathrm{ent}_{j,i}\,(A[\alpha \mid \beta]^*) \;=\; \mathrm{ent}_{i,j}\,(A[\alpha \mid \beta]) \;=\; a_{\alpha(i),\beta(j)}$$

$$\mathrm{ent}_{j,i}\,(A^*[\beta \mid \alpha]) \;=\; a^*_{\beta(j),\alpha(i)} \;=\; a_{\alpha(i),\beta(j)}$$

Here we can clearly see, that these entries agree and hence the matrices are equal as a whole. But as the determinant is invariant under transposition this implies

$$\det\,(A[\alpha \mid \beta]) \;=\; \det\,(A^*[\beta \mid \alpha])$$

Varying α and β over all ascending chains of indexes in $\mathrm{Asc}(r,m)$ and $\mathrm{Asc}(r,n)$ respectively we collect all the minors of A and A^*

$$\begin{aligned}\mathrm{Minor}_r(A) &= \{\,\det\,(A[\alpha \mid \beta]) \mid \alpha \in \mathrm{Asc}(r,m),\, \beta \in \mathrm{Asc}(r,n)\,\}\\ &= \{\,\det\,(A^*[\beta \mid \alpha]) \mid \alpha \in \mathrm{Asc}(r,m),\, \beta \in \mathrm{Asc}(r,n)\,\}\\ &= \mathrm{Minor}_r(A^*)\end{aligned}$$

In particular we have $\mathrm{Minor}_r(A) = \{0\}$ if and only if $\mathrm{Minor}_r(A^*) = \{0\}$. And as this have been used to define the minorial rank we have $\text{m-rank}(A) = \text{m-rank}(A^*)$. As the Fitting ideal $\mathfrak{f}_r(A)$ is generated by $\mathrm{Minor}_r(A)$ we also find $\mathfrak{f}_r(A) = \mathfrak{f}_r(A^*)$. But as the annihilators of these ideals have been used to define the Fitting rank, we clearly have $\text{f-rank}(A) = \text{f-rank}(A^*)$, as well.

(ii) The proof of this statement is a tedious distinction of several cases - it will be conducted in several steps - the first two steps are the technical part, the later parts will be applications of this, that will yield the claim by induction

- We will first prove that for any permutation matrix $P \in \mathrm{mat}_m R$

$$\pm\,\mathrm{Minor}_r(P\,A) \;\subseteq\; \pm\,\mathrm{Minor}_r(A)$$

Thus choose any $\alpha \in \mathrm{Asc}(r,m)$ and $\beta \in \mathrm{Asc}(r,n)$ and suppose $P = P(\sigma)$. Then define $\alpha' \in \mathrm{Asc}(r,m)$ to be the chain of indexes with scope $\alpha'(1\ldots r) = \sigma(\alpha(1\ldots r))$ and define $\sigma' \in S_r$ to be the permutation that satisfies $\alpha' \circ \sigma' = \sigma \circ \alpha$. Then it is clear that

$$P(\sigma)A\,[\alpha \mid \beta] \;=\; P(\sigma')\,A[\alpha' \mid \beta]$$

And hence the minor of PA selected by $[\alpha \mid \beta]$ is just the minor of A selected by $[\alpha' \mid \beta]$ (up to the sign of $P(\sigma')$).

- Now we will prove that for any transvection matrix $T \in \mathrm{mat}_m(R)$

$$\mathrm{Minor}_r(T\,A) \;\subseteq\; \mathrm{Minor}_r(A)$$

Thus choose any $\alpha \in \mathrm{Asc}(r,m)$ and $\gamma \in \mathrm{Asc}(r,n)$, then the Cauchy-Binet-formula reads as

$$\det(TA[\alpha \mid \gamma]) \;=\; \sum_{\beta \in \mathrm{Asc}(r,m)} \det(T[\alpha \mid \beta])\det(A[\beta \mid \gamma])$$

It is clear that the submatrix $T[\alpha \mid \beta]$ is a triangular matrix, since T was such. Thus the determinant only depends on the entries in the diagonal. In the case $\alpha = \beta$ all these diagonal entries are 1 and hence $\det(\mathrm{ent}_{\alpha,\alpha} T) = 1$. In the case $\alpha \neq \beta$ there is (at least one) 0 on the diagonal and hence $\det(T[\alpha \mid \beta]) = 0$. Thus the sum over β collapses to the case $\beta = \alpha$ and hence

$$\det(TA\,[\alpha \mid \gamma]) \;=\; \det(A[\alpha \mid \gamma])$$

In other words the respective minor just remains unchanged.

- In the previous two steps we have seen that for any elementary matrix $E \in \mathrm{mat}_m(R)$ we get

$$\pm\,\mathrm{Minor}_r(E\,A) \;\subseteq\; \pm\,\mathrm{Minor}_r(A)$$

But with E also E^{-1} is an elementary matrix and $A = E^{-1}\,E\,A$. Therefore we can use this inclusion twice to obtain

$$\pm\,\mathrm{Minor}_r(A) \;\subseteq\; \pm\,\mathrm{Minor}_r(E\,A) \;\subseteq\; \pm\,\mathrm{Minor}_r(A)$$

- Thus we have seen that for any elementary matrix $E \in \mathrm{mat}_m R$

$$\pm\,\mathrm{Minor}_r(E\,A) \;=\; \pm\,\mathrm{Minor}_r(A)$$

As the determinant is invariant under transposition of matrices we see that for any elementary matrix $F \in \mathrm{mat}_n R$ we also get

$$\pm\,\mathrm{Minor}_r(A\,F) \;=\; \pm\,\mathrm{Minor}_r(A)$$

- Thus if A and B are elementary equivalent by virtue of the matrices $E_1, \ldots, E_r \in \mathrm{mat}_m R$ and $F_1, \ldots, F_s \in \mathrm{mat}_n R$

$$A \;\equiv\; B \;=\; E_1 \ldots E_r\,A\,F_1 \ldots F_s$$

Then we may easily use induction on the number $r + s$ of elementary matrices taking the previous part as the induction step.

(iii) For $r = 1$ the statements are trivial, as $\mathfrak{f}_0(A) = R$ and $\mathfrak{f}_1(A) \subseteq \mathfrak{f}_1(A)^1$ is clear. Thus let us consider $r \geq 2$ only: If $m \in \mathrm{Minor}_r(A)$ is an r-minor of A, then $m = \det(A')$ for some $(r \times r)$-submatrix A' of A. But using Laplace expansion of A' along the first column we see that

$$m \;=\; \sum_{i=1}^{r} (-1)^{i+1} a'_{i,1} \det(A'_{i,1})$$

It is clear that $\det(A'_{i,1}) \in \mathrm{Minor}_{r-1}(A)$ is an $(r-1)$-minor of A. Thus if $\mathrm{Minor}_{r-1}(A) = \{0\}$ then all these $\det(A'_{i,1}) = 0$ are zero and hence $m = \det(A') = 0$, as well. Therefore we have

$$\mathrm{Minor}_{r-1}(A) \;=\; \{0\} \quad\Longrightarrow\quad \mathrm{Minor}_r(A) \;=\; \{0\}$$

Also we find $m \in \mathrm{Lh}(\mathrm{Minor}_{r-1}(A)) \;=\; \mathfrak{f}_{r-1}(A)$. But as m was any r-minor of A this means

$\mathrm{Minor}_r(A) \subseteq \mathfrak{f}_{r-1}(A)$ and hence even

$$\mathfrak{f}_r(A) \quad \subseteq \quad \mathfrak{f}_{r-1}(A)$$

In fact we find even more: Let us finally prove $\mathrm{Minor}_r(A) \subseteq \mathfrak{f}_1(A)^r$ by induction on r. The case $r = 1$ is trivial, so by induction hypothesis we already have $\mathrm{Minor}_{r-1}(A) \in \mathfrak{f}_1(A)^{r-1}$. Looking at m above we note, that $a'_{i,1} \in \mathfrak{f}_1(A)$ and $\det(A'_{i,1}) \in \mathrm{Minor}_{r-1}(A)$. By induction hypothesis this is $\det(A'_{i,1}) \subseteq \mathfrak{f}_1(A)^{r-1}$ such that

$$m \;\in\; \mathfrak{f}_1(A) \cdot \mathfrak{f}_1(A)^{r-1} \;=\; \mathfrak{f}_1(A)^r$$

As $m \in \mathrm{Minor}_r(A)$ has been an arbitrary minor of A, this of course implies $\mathrm{Minor}_r(A) \subseteq \mathfrak{f}_1(A)^r$ and hence $\mathfrak{f}_r(A) \subseteq \mathfrak{f}_1(A)^r$.

(iv) Since the fitting ideal $\mathfrak{f}_r(A)$ is generated by the set $\mathrm{Minor}_r(A)$ of r-minors of A we can cite proposition (3.22.(iv)) to see

$$\begin{aligned} \mathrm{ann}\,(\mathfrak{f}_r(A)) &= \mathrm{ann}\,(\mathrm{Minor}_r(A)) \\ &= \bigcap \{\, \mathrm{ann}(m) \mid m \in \mathrm{Minor}_r(A) \,\} \\ &= \{\, a \in R \mid \forall\, m \in \mathrm{Minor}_r(A) \,:\, am = 0 \,\} \end{aligned}$$

And as by (ii) we have $\mathfrak{f}_r(A) \subseteq \mathfrak{f}_{r-1}(A)$ then annihilators of these ideals clearly satisfy the converse inclusion

$$\mathrm{ann}\,(\mathfrak{f}_{r-1}(A)) \;\subseteq\; \mathrm{ann}\,(\mathfrak{f}_r(A))$$

(v) If $A' = A[\alpha \mid \beta]$ is a submatrix of A, then $\mathrm{Minor}_r(A') \subseteq \mathrm{Minor}_r(A)$ is obvious, for any $r \in \mathbb{N}$. If now $r = \text{m-rank}(A')$ then by definition there is some $m \in \mathrm{Minor}_r(A')$ such that $m \neq 0$. But then $0 \neq m \in \mathrm{Minor}_r(A)$, as well. And as the minorial rank of A has been defined to be the *maximal* number r with this property we have

$$\text{m-rank}(A') \;=\; r \;\leq\; \text{m-rank}(A)$$

Also $\mathrm{Minor}_r(A') \subseteq \mathrm{Minor}_r(A)$ implies $\mathfrak{f}_r(A') \subseteq \mathfrak{f}_r(A)$ and hence the annihilator ideals satisfy $\mathrm{ann}(\mathfrak{f}_r(A)) \subseteq \mathrm{ann}(\mathfrak{f}_r(A'))$ the opposite inclusion. If now $r = \text{f-rank}(A')$ then $\mathrm{ann}(\mathfrak{f}_r(A')) = 0$ and due to the inclusion $\mathrm{ann}(\mathfrak{f}_r(A)) = 0$. And as the Fitting rank of A has been defined to be the *maximal* number r with this property we have

$$\text{f-rank}(A') \;=\; r \;\leq\; \text{f-rank}(A)$$

(vi) Let us first assume $A \in \mathrm{mat}_r(R)$ is a square matrix with $\text{f-rank}(A) = r$. Then we have to show $\text{r-rank}(A) = \text{c-rank}(A) = r$. By assumption

$$0 \;=\; \mathrm{ann}(\mathfrak{f}_r(A)) \;=\; \mathrm{ann}(\det(A))$$

Let now $A_j := \mathrm{col}_j(A)$ be the j-th column of A and consider some $a_j \in R$ such that the following

linear relation holds true

$$\sum_{j=1}^{n} a_j A_j \;=\; 0$$

We will prove, that in this case we already have $a_1 = 0$. In complete analogy we could prove $a_j = 0$ for any $j \in 1 \ldots r$, but specialize to the case $j = 1$ for ease of notation. To do this simply compute

$$\begin{aligned} a_1 \det(A) &= a_1 \det(A_1, A_2, \ldots, A_n) \;=\; \det(a_1 A_1, A_2, \ldots, A_n) \\ &= \det\left(\sum_{j=2}^{n} -a_j A_j, A_2, \ldots, A_n\right) \\ &= \sum_{j=2}^{n} -a_j \det(A_j, A_2, \ldots, A_n) \end{aligned}$$

As any determinant in the last term contains A_j twice, it vanishes. That is we have $a_1 \det(A) = 0$, but as $\operatorname{ann}(\det(A)) = 0$ this implies $a_1 = 0$. That is the columns A_1 to A_n of A are linearly independent, c-rank$(A) = r$. And as this has been proved for any matrix A, we can apply it to A^*: By (i) we have f-rank(A^*) = f-rank$(A) = r$ and hence we find r-rank(A) = c-rank$(A^*) = r$, as well.

For the general statement let $A' := A[\alpha \mid \beta] \in \mathrm{mat}_r(R)$. By assumption we have $\operatorname{ann}(\det(A')) = 0$ such that by the above we find r-rank$(A') = r$ and c-rank$(A') = r$. But as the rank of the submatrix A' cannot exceed the rank of A - this is (4.72.(iii)) - we find c-rank$(A) \geq$ c-rank$(A') = r$ and r-rank$(A) \geq$ r-rank$(A') = r$.

(vii) Let $r :=$ m-rank(AB) and suppose $r >$ m-rank(A). This would mean $\det(A[\alpha \mid \beta]) = 0$ for any $\alpha \in \mathrm{Asc}(r,k)$ and any $\beta \in \mathrm{Asc}(r,m)$. Likewise if $r >$ m-rank(B) then $\det(B[\beta \mid \gamma]) = 0$ for any $\beta \in \mathrm{Asc}(r,m)$ and any $\gamma \in \mathrm{Asc}(r,n)$. Now take a look at the formula of Cauchy-Binet

$$\det\big(AB[\alpha \mid \gamma]\big) \;=\; \sum_{\beta \in \mathrm{Asc}(r,m)} \det\big(A[\alpha \mid \beta]\big) \det\big(B[\beta \mid \gamma]\big)$$

But by assumption $r =$ m-rank(AB) there are some α and γ such that $\det(AB[\alpha \mid \gamma]) \neq 0$. Thus neither all the $\det(A[\alpha \mid \beta])$ nor all the $\det(B[\beta \mid \gamma])$ may all be zero. In particular this means $r \leq$ m-rank(A) and $r \leq$ m-rank(B).

(viii) First of all we note, that all these statements are false in case $m < n$: By definition we have f-rank$(A) \leq m < n$ and c-rank$(A) \leq m < n$ is true by (4.72.(i)). In this case we also have $\mathrm{kn}(A) \neq 0$, since

$$R^n \;\cong_{\mathsf{m}}\; R^n \big/ \mathrm{kn}(A) \;\cong_{\mathsf{m}}\; \mathrm{im}(A) \;\subseteq\; R^m$$

Clearly R^n contains n linearly independent elements [namely $e_j \in R^n$ the Euclidean base vectors]. But as R^m is generated by $m < n$ elements [namely the Euclidean base vectors $e_i \in R^m$] any n elements of R^m are linearly dependent, according to (3.99.(i)). But this contradicts the injective homomorphism $R^n \hookrightarrow R^m$ above. Thus throughout this proof we may assume $n \leq m$.

Let us begin with $\mathrm{kn}(A) = 0 \iff$ c-rank$(A) = n$. Denote the column vectors of A by $A_j :=$

$\mathrm{col}_j(A)$ where $j \in 1 \ldots n$ and suppose there was some relation of the form

$$x_1 A_1 + x_2 A_2 + \cdots + x_n A_n \;=\; 0 \;\in\; R^m$$

Note that $Ax = A_1 x_1 + A_n x_n$ is precisely that sum. Thus if we have c-rank$(A) = n$, then the A_j are linearly independent, such that $Ax = 0$ implies $x = 0$, which is just a reformulation of $\mathrm{kn}(A) = 0$. And if c-rank$(A) < n$ then there is some $x \in R^n$ with $x \neq 0$ but $Ax = 0$ which in turn means $x \in \mathrm{kn}(A)$ such that is this case $\mathrm{kn}(A) \neq 0$.

The hard part is the implication $\mathrm{kn}(A) = 0 \implies$ f-rank$(A) = n$, which we will do now. To do this we will use induction on n: The case $n = 1$ is quite obvious: We need to show $\mathrm{ann}(\mathrm{Minor}_1(A)) = 0$. In this case A is a single column vector $A = (c_1\, c_2\, \ldots\, c_m)^*$ only and hence $\mathrm{Minor}_1(A) = \{\, c_1, \ldots, c_m \,\}$ If we had $a \in \mathrm{ann}(\mathrm{Minor}_1(A))$ for some $a \neq 0$ then $a(c_1, c_2, \ldots, c_m) = 0 \in R^m$. That is the column vector of A would be linearly dependent (itself) in contradiction to c-rank$(A) = 1$. Thus we conclude f-rank$(A) = 1$, as well.

The clever part is the induction step: Suppose we have the implication c-rank$(A') = n-1 \implies$ f-rank$(A') = n-1$ for any $A' \in \mathrm{mat}_{q,n-1}(R)$ with $n - 1 \leq q$. Then we need to show this property for $A \in \mathrm{mat}_{m,n}(R)$ with $n \leq m$. That is we need $\mathrm{ann}(\mathrm{Minor}_n(A)) = 0$. Again we assume the opposite - there was some $a \neq 0$ with $a \in \mathrm{ann}(\mathrm{Minor}_n(R))$. Then for any $\alpha \in \mathrm{Asc}(n, m)$ let us denote the submatrix

$$A_\alpha \;:=\; A[\alpha \mid \mathbb{1}] \;\in\; \mathrm{mat}_n(A)$$

By (15.1) we know that all the coefficients of $AA^\#_\alpha$ are either 0 or $\pm m$ for some n-minor $m \in \mathrm{Minor}_n(A)$ of A. In particular

$$A\big(aA^\#_\alpha\big) \;=\; aAA^\#_\alpha \;=\; 0 \;\in \mathrm{mat}_{m,n}(R)$$

That is $A\, a\, \mathrm{col}_j(A^\#_\alpha) = 0 \in R^m$ for any $j \in 1 \ldots n$. But by assumption $\mathrm{kn}(A) = 0$ this means $a\, \mathrm{col}_j(A^\#_\alpha) = 0 \in R^n$ and as this is true for any j we find the annihilation

$$\forall\, \alpha \in \mathrm{Asc}(n, m) \;:\; aA^\#_\alpha \;=\; 0 \;\in\; \mathrm{mat}_n(R)$$

But clearly the coefficients of $A^\#_\alpha$ are $(n-1)$-minors of A and as α runs along all ascending chains of indices we have

$$\mathrm{Minor}_{n-1}(A) \;=\; \left\{\, a^\#_{\alpha(i),j} \mid \alpha \in \mathrm{Asc}(n, m),\, i, j \in 1 \ldots n \,\right\}$$

Since a annihilates all these coefficients we have $a \in \mathrm{ann}(\mathrm{Minor}_{n-1}(A))$ already. But if we look at the matrix

$$A' \;:=\; \begin{pmatrix} | & | & & | \\ \mathrm{col}_1(A) & \mathrm{col}_2(A) & \ldots & \mathrm{col}_{n-1}(A) \\ | & | & & | \end{pmatrix} \;\in\; \mathrm{mat}_{m,n-1}(R)$$

we have c-rank$(A') = n - 1$ and hence $\mathrm{kn}(A') = 0$ such that by induction hypothesis we have f-rank$(A') = n - 1$ [and $n - 1 \leq n \leq m$] again. That is $\mathrm{ann}(\mathrm{Minor}_{n-1}(A')) = 0$, but as the minors

of A' trivially are minors of A [that is $\mathrm{Minor}_{n-1}(A') \subseteq \mathrm{Minor}_{n-1}(A)$] we have

$$0 \neq a \;\in\; \mathrm{ann}(\mathrm{Minor}_{n-1}(A)) \;\subseteq\; \mathrm{ann}(\mathrm{Minor}_{n-1}(A')) \;=\; 0$$

That is we have arrived at a contradiction, which means there is no $a \neq 0$ with $a \in \mathrm{ann}(\mathrm{Minor}_n(A))$ such that $\text{f-rank}(A) = n$. So at long last we have arrived at the implication

$$\text{c-rank}(A) \;=\; n \quad\Longrightarrow\quad \text{f-rank}(A) \;=\; n$$

We finally have to show $\text{f-rank}(A) = n \implies \mathrm{kn}(A) = 0$ to complete the equivalence. This proof is easy again: As before let us denote $A_\alpha := A[\alpha \mid \mathbb{1}]$ again, for any $\alpha \in \mathrm{Asc}(n,m)$. Suppose we had some $x \in R^n$ with $x \neq 0$ and $Ax = 0$. As any A_α has the same rows as A (only a subset of these) this also means $A_\alpha x = 0$. But then

$$\det(A_\alpha)\, x \;=\; A_\alpha^\# A_\alpha\, x \;=\; A_\alpha^\# 0 \;=\; 0 \;\in\; R^n$$

Since there is some $k \in 1\ldots n$ with $x_k \neq 0$ this means $x_k \det(A_\alpha) = 0$. But as this is true for any $\alpha \in \mathrm{Asc}(n,m)$ we have $x_k m = 0$ for any $m \in \mathrm{Minor}_n(A)$ and hence $x_k \in \mathrm{ann}(\mathrm{Minor}_n(A))$. In particular we would have $\text{f-rank}(A) < n$ in contradiction to the assumption. And this means $Ax = 0 \implies x = 0$ such that $\mathrm{kn}(A) = 0$.

□

Proof of (4.86):
The theorem has three separate parts: The better the base ring R is, the more equalities we get for the rank of a matrix. We start with an arbitrary **commutative ring** $R \neq 0$. The first, easy step is to prove that generally $\text{f-rank}(A) \leq \text{m-rank}(A)$. But if $\mathrm{Minor}_r(A) = \{0\}$ then (as all $a \in R$ satisfy $a \cdot 0 = 0$) clearly $\mathrm{ann}(\mathfrak{f}_r(A)) = R \neq 0$. By negation this is the implication

$$\mathrm{ann}(\mathfrak{f}_r(A)) = 0 \quad\Longrightarrow\quad \mathrm{Minor}_r(A) \neq \{0\}$$

Thus if $r = \text{f-rank}(A)$ then this means $\mathrm{ann}(\mathfrak{f}_r(A)) = 0$ such that $\mathrm{Minor}_r(A) \neq \{0\}$. But as $\text{m-rank}(A)$ was defined to be the maximal number r with $\mathrm{Minor}_r(A) \neq \{0\}$ we find $\text{f-rank}(A) \leq \text{m-rank}(A)$.

In the next part we need to prove $\text{c-rank}(A) \leq \text{f-rank}(A)$. Likewise take $\text{c-rank}(A) = r$ then there is some $\beta \in \mathrm{Asc}(r,n)$ such that the submatrix $A' := A[\mathbb{1} \mid \beta] \in \mathrm{mat}_{m,r}(R)$ has full rank $\text{c-rank}(A') = r$. But then we find $\text{f-rank}(A') = r$ according to (4.83.(vii)) and hence

$$\text{f-rank}(A) \;\geq\; \text{f-rank}(A') \;=\; r \;=\; \text{c-rank}(A)$$

by (4.83.(iv)). Note that thereby the requirement $r \leq m$ is always satisfied since $r = \text{c-rank}(A) \leq m$ according to (4.72.(i)). Thus we have proved $\text{c-rank}(A) \leq \text{f-rank}(A)$ for a general matrix A. Once this is done it is clear that the row-rank of A also is bound, since $\text{r-rank}(A) = \text{c-rank}(A^*) \leq \text{f-rank}(A^*) = \text{f-rank}(A)$, where we used (4.83.(i)).

For an **integral domain** R we have already seen $\text{c-rank}(A) = \text{r-rank}(A)$ in (4.72.(vi)) and the equality $\text{f-rank}(A) = \text{m-rank}(A)$ is easy to see: In an integral domain $\mathrm{Minor}_r(A) = \{0\}$ even is equivalent to

$\operatorname{ann}(\mathfrak{f}_r(A)) \neq 0$. By negation this is the equivalence of

$$\operatorname{Minor}_r(A) \neq \{0\} \iff \operatorname{ann}(\mathfrak{f}_r(A)) = 0$$

As the Fitting and the minorial rank of A have been defined to be the maximal number r with the respective property they have to be equal

$$\text{m-rank}(A) \;=\; \text{f-rank}(A)$$

So it suffices to show $\text{c-rank}(A) = \text{m-rank}(A)$, which we will do now: If $r = \text{m-rank}(A)$, then there are some $\alpha \in \operatorname{Asc}(r,m)$ and $\beta \in \operatorname{Asc}(r,n)$ with

$$\det\big(A[\alpha \mid \beta]\big) \;\neq\; 0$$

Let us define the projection $P_\alpha : R^m \to R^r$ by $P_\alpha(a) := a'$ where for $a = (a_1,\ldots,a_m)$ we let $a' := (a_{\alpha(1)},\ldots,a_{\alpha(r)})$. If we also abbreviate the columns of A by $c_j := \operatorname{col}_j(A)$ for any $j \in 1\ldots n$ then clearly

$$A[\alpha \mid \beta] \;=\; \begin{pmatrix} | & & | \\ P_\alpha(c_{\beta(1)}) & \ldots & P_\alpha(c_{\beta(r)}) \\ | & & | \end{pmatrix}$$

Since the determinant of this matrix is non-zero corollary (4.65.(ii)) tells us, that the $P_\alpha(c_{\beta(i)})$ are linearly independent. Now suppose there was an R-linear combination $a_1 c_{\beta(1)} + \cdots + a_r c_{\beta(r)} = 0$ in R^m, then

$$0 \;=\; P_\alpha\left(\sum_{i=1}^{r} a_i c_{\beta(i)}\right) \;=\; \sum_{i=1}^{r} a_i P_\alpha\left(c_{\beta(i)}\right)$$

But since these are R-linearly independent we have $a_i = 0$ for all $i \in 1\ldots r$ and this means the $c_{\beta(i)}$ themselves are R-linearly independent. In particular A has r many linearly independent rows and hence

$$\text{m-rank}(A) \;= r \;\leq\; \text{c-rank}(A)$$

Conversely let $r := \text{c-rank}(A)$, then there is some $\beta \in \operatorname{Asc}(r,n)$ such that the columns $\left\{ c_{\beta(1)},\ldots,c_{\beta(r)} \right\} \subseteq R^m$ are R-linearly independent. That is the submatrix A' of A

$$A' \;:=\; A[\mathbb{1} \mid \beta] \;=\; \begin{pmatrix} | & & | \\ c_{\beta(1)} & \ldots & c_{\beta(r)} \\ | & & | \end{pmatrix}$$

has $\text{c-rank}(A') = r$. But as $\text{r-rank}(A') = \text{c-rank}(A') = r$ this means, that there also is some $\alpha \in \operatorname{Asc}(r,m)$ such that $\left\{ \operatorname{row}_{\alpha(i)}(A') \mid i \in 1\ldots r \right\}$ is R-linearly independent. But this is

$$A[\alpha \mid \beta] \;=\; \begin{pmatrix} \text{---} & \operatorname{row}_{\alpha(1)}(A') & \text{---} \\ & \vdots & \\ \text{---} & \operatorname{row}_{\alpha(r)}(A') & \text{---} \end{pmatrix}$$

As the rows of $A[\alpha \mid \beta]$ are linearly independent corollary (4.65.(ii)) again intervenes to provide $\det(A[\alpha \mid \beta]) \neq 0$. That is we have found an $(r \times r)$-minor of A that is non-zero and hence

$$\text{c-rank}(A) \;\; = r \;\; \leq \;\; \text{m-rank}(A)$$

Finally, in case R even is a **field**, it is both an integral domain and a skew field. But (4.72.(vii)) tells us, that in a skew field the image-rank then equals the column rank $\text{i-rank}(A) = \text{c-rank}(A)$ and all the other equalities have already been shown in case of an integral domain. □

Proof of (4.88):
The proof of (i) is a non-algorithmical trick computation. However it is far from being trivial and hence presented here. Then (ii) is clear, simply apply (i) to the transpose matrix A^* of A.

(ii) We begin by proving the existence of such a representation of A by a divisibly ascending chain of scalar factors. This will be the major part of the proof, the representation of the scalar factors in terms of minors then is simple

- First of all we define - for any matrix $0 \neq A = (a_{i,j}) \in \text{mat}_{m\times n}R$

$$\nu(A) \;\; := \;\; \min\{\, \nu(a_{i,j}) \mid i \in 1 \ldots m,\, j \in 1 \ldots n,\, a_{i,j} \neq 0 \,\}$$

 Now we regard the set of all $\nu(B)$ where B is a matrix that is elementarily equivalent to A

$$\{\, \nu(B) \mid B \in \text{mat}_{m\times n}R,\, A \equiv B \,\} \;\; \subseteq \;\; \mathbb{N}$$

 As $\mathbb{N}$ is well-ordered this set has a minimum and we choose such a matrix M for which $\nu(M)$ is minimal.

- Suppose that the (i,j)-th entry $m_{i,j}$ of M takes the minimal value $\nu(M) = \nu(m_{i,j})$. Then we may rearrange M to shift $m_{i,j}$ to the position $(1,1)$ and we denote this rearranged matrix by

$$M' \;\; := \;\; P(1\,i)\, M\, P(1\,j)$$

 I.e. $\text{ent}_{1,1}M' = \text{ent}_{i,j}M = m_{i,j}$ and hence $\nu(M') = \nu(\text{ent}_{1,1}M')$. Thus we may equally well assume that $\nu(M) = \nu(m_{1,1})$

- We now claim that $m_{1,1}$ divides all the entries $m_{i,1}$ in the first column of M. To see this we use division with remainder

$$m_{i,1} \;\; = \;\; p_i m_{1,1} + r_i \quad \text{where} \quad 0 \;\leq\; \nu(r_i) \;<\; \nu(m_{1,1})$$

 Suppose $r_i \neq 0$ then we would obtain a matrix $B := T_{i,1}(-p_i)\, M$ being elementary equivalent to M and hence to A, too. Clearly the $(i,1)$-entry of B is given to be

$$[\text{row}_i B]_1 \;\; = \;\; [\text{row}_i M - p_i \text{row}_1 M]_1 \;\; = \;\; m_{i,1} - p_i m_{1,1} \;\; = \;\; r_i$$

 Therefore $\nu(B) \leq \nu(r_i) < \nu(m_{1,1}) = \nu(M)$, but M was chosen to be minimal, so this cannot occur.

- Analogously we see that $m_{1,1}$ divides all the entries $m_{1,j}$ in the first row of M. We use division with remainder again

$$m_{1,j} \;=\; q_j m_{1,1} + s_i \quad \text{where} \quad 0 \;\leq\; \nu(s_j) \;<\; \nu(m_{1,1})$$

Suppose $s_j \neq 0$ then we would obtain a matrix $B := M\,T_{1,j}(-q_j)$ that is elementary equivalent to A again. Clearly the $(1,j)$-entry of B is then given to be

$$\big[\mathrm{col}_j B\big]_1 \;=\; \big[\mathrm{col}_j M - q_j \mathrm{col}_1 M\big]_1 \;=\; m_{1,j} - q_j m_{1,1} \;=\; s_j$$

Therefore $\nu(B) \leq \nu(s_j) < \nu(m_{1,1}) = \nu(M)$, but M was chosen to be minimal, so this cannot occur.

- We now use elementary transpositions to replace the entries of the first column $m_{i,1} \mapsto r_i = 0$ and of the first row $m_{1,j} \mapsto s_j = 0$. And this obviously is accomplished by

$$N \;:=\; T_{2,1}(-p_2)\ldots T_{m,1}(-p_m)\,M\,T_{1,2}(-q_2)\ldots T_{1,n}(-q_n)$$

As we have seen this matrix N now is of the following form

$$N \;=\; \begin{pmatrix} m_{1,1} & 0 & \ldots & 0 \\ 0 & * & \ldots & * \\ \vdots & \vdots & & \vdots \\ 0 & * & \ldots & * \end{pmatrix}$$

Let us abbreviate $N = S\,M\,T$ where S and T denote the respective products of transposition matrices. Then we will have a look at the entries of N for

$$\begin{aligned} \mathrm{ent}_{i,j} N &= [\mathrm{col}_j S\,M\,T]_i \\ &= [\mathrm{col}_j S\,M - q_j \mathrm{col}_1 S\,M]_i \\ &= \mathrm{ent}_{i,j} S\,M - q_j \mathrm{ent}_{i,1} S\,M \\ &= m_{i,j} - p_i m_{1,j} \\ &= m_{i,j} - p_i q_j m_{1,1} \end{aligned}$$

- We finally prove that $m_{1,1} = n_{1,1}$ even divides any other entry $n_{i,j} = m_{i,j} - p_i q_j m_{1,1}$ (with $i \in 2\ldots m$ and $j \in 2\ldots n$) of N as well. First we use division with remainder once more

$$n_{i,j} \;=\; h_{i,j} n_{1,1} + k_{i,j} \quad \text{where} \quad 0 \;\leq\; \nu(k_{i,j}) \;<\; \nu(n_{1,1})$$

Now regard the matrix $N' := T_{i,1}(1)\,N$, clearly the i-th row of N' assumes the form

$$\mathrm{row}_i N' \;=\; \mathrm{row}_i N + \mathrm{row}_1 N \;=\; \begin{pmatrix} n_{1,1} & n_{i,2} & \ldots & n_{i,n} \end{pmatrix}$$

Thus defining $N'' := N'\,T_{1,j}(-h_{i,j})$ yields another matrix with

$$\mathrm{col}_j N'' \;=\; \mathrm{col}_j N' - h_{i,j}\mathrm{col}_1 N' \;=\; \begin{pmatrix} \vdots \\ k_{i,j} \\ \vdots \end{pmatrix}$$

Hence $\nu(N'') \leq \nu(k_{i,j}) < \nu(n_{1,1}) = \nu(M)$. But N'' is elementarily equivalent to N and hence to A and as M was chosen to minimal among these matrices we find $k_{i,j} = 0$ again.

- Thus we have decomposed N into a scalar block $(m_{1,1})$ and a scalar multiple of a block A_1 of the size $(m-1)\times(n-1)$

$$N \;=\; (m_{1,1}) \oplus (m_{1,1}\,A_1)$$

Thus we let $d_1 := m_{1,1}$ and recurse the entire process starting with A_1. Using induction we find after $m-1$ steps that A truly is equivalent to a matrix D of the claimed form.

- Until now we have shown that A is elementarily equivalent to D

$$A \;\equiv\; D \;=\; \begin{pmatrix} d_1 & & 0 & 0 & \dots & 0 \\ & \ddots & & \vdots & & \vdots \\ 0 & & d_m & 0 & \dots & 0 \end{pmatrix}$$

As the determinant of a submatrix of D always is a product of the coefficients of the submatrix (and hence of D) we find

$$\{0\} \cup \left\{ d_{\alpha(1)} \dots d_{\alpha(r)} \mid \alpha \in A(r,m) \right\} \;=\; \mathrm{Minor}_r D$$

Since the d_i form a divisibly ascending chain it is clear that the greatest common divisor of these elements is just $d_1 \dots d_r$. But by (ii) the gcd of the minors is invariant under elementary equivalence and therefore

$$d_1 \dots d_r \;\in\; \gcd(\mathrm{Minor}_r D) \;=\; \gcd(\mathrm{Minor}_r A)$$

□

Proof of (4.93):
The only thing we need to check here are the additional properties (4) and (5) of a sesqui-linear form s. But this is straightforward: Let $x, y, z \in M$ and $a \in R$, then we may compute

$$\begin{aligned} s(x \mid y+z) &= \varepsilon\big(s(y+z \mid x)\big) \;=\; \varepsilon\big(s(y \mid x) + s(z \mid x)\big) \\ &= \varepsilon\big(s(y \mid x)\big) + \varepsilon\big(s(z \mid x)\big) \;=\; s(x \mid y) + s(x \mid z) \\ s(x \mid ay) &= \varepsilon\big(s(ay \mid x)\big) \;=\; \varepsilon\big(as(y \mid x)\big) \\ &= \varepsilon(a) \cdot \varepsilon\big(s(y \mid x)\big) \;=\; \varepsilon(a) \cdot s(x \mid y) \end{aligned}$$

□

Proof of (4.92):
Consider $t = (t_1, \ldots, t_n)$, $w = (w_1, \ldots, w_n)$ and $z = (z_1, \ldots, z_n) \in \mathbb{C}^n$ where $t_k = r_k + is_k$, $w_k = u_k + iv_k$ and $z_k = x_k + iy_k$ respectively. Then the first few identities are straightforward computations:

$$\begin{aligned}
\langle t + w \mid z\rangle &= \sum_{k=1}^{n} (t_k + w_k)\overline{z}_k \;=\; \sum_{k=1}^{n} t_k\overline{z}_k + \sum_{k=1}^{n} w_k\overline{z}_k \\
&= \langle t \mid z\rangle + \langle w \mid z\rangle \\
\langle aw \mid z\rangle &= \sum_{k=1}^{n} (aw_k)\overline{z}_k \;=\; a\sum_{k=1}^{n} w_k\overline{z}_k \\
&= a\langle w \mid z\rangle \\
\langle z \mid w\rangle &= \sum_{k=1}^{n} z_k\overline{w}_k \;=\; \sum_{k=1}^{n} \overline{z}_k\overline{w}_k \;=\; \overline{\sum_{k=1}^{n} \overline{z}_k w_k} \\
&= \overline{\langle w \mid z\rangle}
\end{aligned}$$

That is we have verified the three properties of a sesqui-linear form with respect to the complex conjugation and hence we already get the other properties, by (4.93). Next we have $w_k\overline{z}_k = (u_k + iv_k)(x_k - iy_k) = (u_k x_k + v_k y_k) + i(u_k y_k - v_k x_k)$. And from this we get

$$\begin{aligned}
\langle w \mid z\rangle &= \sum_{k=1}^{n} w_k\overline{z}_k \\
&= \sum_{k=1}^{n} \big((u_k x_k + v_k y_k) + i(u_k y_k - v_k x_k)\big) \\
&= \langle u, x\rangle + \langle v, y\rangle + i\big(\langle u, y\rangle - \langle v, x\rangle\big)
\end{aligned}$$

Here we can evaluate the real and imaginary part of $\langle w \mid z\rangle$ to find the formulas we have given in the proposition. By the construction of the inner product we have

$$\langle z \mid z\rangle \;=\; \sum_{k=1}^{n} z_k\overline{z}_k \;=\; \sum_{k=1}^{n} |z_k|^2$$

Thus if we take $|z| := (|z_1|, \ldots, |z_n|) \in \mathbb{R}^n$ we see that $\langle z \mid z\rangle = \langle |z|, |z|\rangle$. But as the scalar product on $\mathbb{R}^n$ is positive definite we see that $\langle z \mid z\rangle \geq 0$ is positive and if $\langle z \mid z\rangle = 0$ then we get $|z_k| = 0$ and hence $z_k = 0$ for any $k \in 1 \ldots n$. Hence $\langle z \mid z\rangle = 0$ implies $z = 0$, which means that the inner product even is positive definite. It remains to regard $w \in \mathbb{C}^n$, $z \in \mathbb{C}^m$ and $A \in \mathrm{mat}_{m,n}(\mathbb{C})$, then we compute

$$\begin{aligned}
\langle A\,w \mid z\rangle &= \sum_{r=1}^{m} \left(\sum_{s=1}^{n} a_{r,s} w_s\right) \overline{z}_r \\
&= \sum_{s=1}^{n} w_s \left(\sum_{r=1}^{m} a_{r,s}\overline{z}_r\right) \\
&= \sum_{s=1}^{n} w_s \overline{\sum_{r=1}^{m} \overline{a}_{r,s} z_r} \\
&= \sum_{s=1}^{n} w_s \overline{\sum_{r=1}^{m} \mathrm{ent}_{s,r}(\overline{A}) z_r} \\
&= \langle w \mid \overline{A}\,z\rangle
\end{aligned}$$

□

Proof of (4.97):

(i) Consider a linear relation of the g_i, that is for some $a_i \in R$ we have

$$\sum_{i\in I} a_i m_i \;=\; 0$$

Then for any $j \in J$ we could apply the linear map $x \mapsto s(x \mid m_j)$ to find $a_j = 0$ and thereby the linear independence of the m_i

$$0 = s(0 \mid m_j) = s\left(\sum_{i\in I} a_i m_i \mid m_j\right) = \sum_{i\in I} a_i s(m_i \mid m_j) = \sum_{i\in I} a_i \delta_{i,j} = a_j$$

(ii) As $\{ m_i \mid i \in I \}$ is a basis of M for any $x \in M$ there are uniquely determined coefficients $x_i \in R$ such that x can be written as

$$x \;=\; \sum_{i\in I} x_i m_i$$

For any $j \in I$ now apply $x \mapsto s(x \mid m_j)$ to this equation. Then we find that the coefficient x_j is given to be $x_j = s(x \mid m_j)$

$$s(x \mid m_j) = s\left(\sum_{i\in I} x_i m_i \mid m_j\right) = \sum_{i\in I} x_i s(m_i \mid m_j) = \sum_{i\in I} x_i \delta_{i,j} = x_j$$

(iii) In case of $R = \mathbb{R}$ or $R = \mathbb{C}$ the function r is easy to see: For $x \in M$ just take the positive square root $r(x) := \sqrt{\langle x \mid x\rangle} = \| x \|$. But let us check that it is possible to construct r in the general setting:

Since s is positive definite we have $s(x \mid x) \in Q$ for any $x \in M$ with $x \neq 0$ where $Q := \{ a \cdot \varepsilon(a) \mid a \in R^* \}$. So take a look at the map $\nu : R^* \twoheadrightarrow Q : a \mapsto a \cdot \varepsilon(a)$. We obtain an equivalence relation on R^* by letting $a \sim b$ if and only if $\nu(a) = \nu(b)$. The equivalence classes under this relation are the fibers $[b] = q^{-1}(\{ b \cdot \varepsilon(b) \})$. By the axiom of choice there is a subset $P \subseteq R^*$ such that $\overline{\nu} : P \longleftrightarrow Q : a \mapsto a \cdot \varepsilon(a)$. Now take $r(x) := \overline{\nu}^{-1}(s(x \mid x))$. Then r is a well-defined function r that satisfies $r(x) \in P \subseteq R^*$ and $r(x) \cdot \varepsilon(r(x)) = \overline{\nu}(r(x)) = s(x \mid x)$.

Now that we have defined $r : Q \to R^*$ we also have $N(x) = r(x)^{-1}x$ for $x \neq 0$. Note that $\mathrm{Lh}\{ x \} = \mathrm{Lh}\{ N(x) \}$ since $r(x)$ is a unit of R.

We will now prove that the Gram-Schmidt-Orthogonalisation Process truly yields an ONB of M with respect to s. We will use induction on k to verify the following properties

(1) g_k is well-defined

(1) $\{ g_1, \ldots, g_k \}$ is an ortho-normal system

(3) $\mathrm{Lh}\{ g_1, \ldots, g_k \} = \mathrm{Lh}\{ m_1, \ldots, m_k \}$

Starting with $k = 1$ we have $g_1 = N(m_1)$. And as $\{ m_1, \ldots, m_n \}$ is a basis [in particular linearly independent] we have $m_1 \neq 0$. Thus g_1 is well-defined, $\mathrm{Lh}\{ g_1 \} = \mathrm{Lh}\{ m_1 \}$ and we have

$$s(g_1 \mid g_1) \;=\; s\big(r(m_1)^{-1}m_1 \mid r(m_1)^{-1}m_1\big)$$

$$\begin{aligned} &= r(m_1)^{-1} \cdot \varepsilon(r(m_1)^{-1}) s(m_1 \mid m_1) \\ &= \big(r(m_1) \cdot \varepsilon(r(m_1))\big)^{-1} s(m_1 \mid m_1) \;=\; 1 \end{aligned}$$

For the induction step we may suppose the above statements (1), (2) and (3) for $\{ g_1, \ldots, g_{k-1} \}$. As $x \mapsto s(x \mid g_i)$ is linear, so is

$$P \;:\; M \to M \;:\; x \mapsto \sum_{i=1}^{k-1} s(x \mid g_i) g_i$$

And by induction hypothesis we have $\mathrm{im}(P) = \mathrm{Lh}\{ m_1, \ldots, m_{k-1} \}$. And as $\{ m_1, \ldots, m_n \}$ is a basis we therefore have $m_k \notin \mathrm{im}(P)$. In particular $q_k := m_k - P(m_k) \neq 0$ such that $a_k := r(q_k)$ and thereby $g_k = N(q_k) = a_k^{-1} q_k$ are well defined. Thereby $g_k \in \mathrm{im}(P) + Rm_k$ and conversely $m_k = P(m_k) + q_k \in \mathrm{im}(P) + Rg_k$ such that we also have property (3). It remains to prove (2): By induction hypothesis we already know $s(g_i \mid g_j) = \delta_{i,j}$ for any $i, j \in 1 \ldots k-1$. Now for any $j < k$ we compute

$$\begin{aligned} s(g_k \mid g_j) &= s\left(a_k^{-1} \big(m_k - P(m_k)\big) \mid g_j \right) \\ &= a_k^{-1} \big(s(m_k \mid g_j) - s(P(m_k) \mid g_j) \big) \\ &= a_k^{-1} \left(s(m_k \mid g_j) - \sum_{i=1}^{k-1} s(m_k \mid g_i)\, s(g_i \mid g_j) \right) \\ &= a_k^{-1} \left(s(m_k \mid g_j) - \sum_{i=1}^{k-1} s(m_k \mid g_i)\, \delta_{i,j} \right) \\ &= a_k^{-1} \big(s(m_k \mid g_j) - s(m_k \mid g_j) \big) \;=\; 0 \end{aligned}$$

Note that with $g(g_k \mid g_j) = 0$ we also have $s(g_j \mid g_k) = 0$ as s is symmetric up to ε and this is a homomorphism of rings. For $j = k$:

$$\begin{aligned} s(g_k \mid g_k) &= s\big(a_k^{-1} q_k \mid a_k^{-1} q_k\big) \\ &= a_k^{-1}\, \varepsilon\big(a_k^{-1}\big) s\big(q_k \mid q_k\big) \\ &= \big(a_k\, \varepsilon(a_k)\big)^{-1} s\big(q_k \mid q_k\big) \;=\; 1 \end{aligned}$$

The latter, as $a_k = r(q_k)$ and $r(q_k)\varepsilon(r(q_k)) = s(q_k \mid q_k)$ such that the inverse of $a_k \varepsilon(a_k)$ cancels $s(q_k \mid q_k)$. Altogether the induction is complete and thereby $\{ g_1, \ldots, g_n \}$ is an ortho-normal system again, that generates M. By (i) we know that any ortho-normal system is linear independent and hence $\{ g_1, \ldots, g_n \}$ is a basis of M.

□

Proof of (4.98):
It is clear that $U^\perp$ is a subspace of V as it is the intersection of the kernels of $x \mapsto s(x \mid u)$ which are subspaces of V. Also it is easy to see that $U \cap U^\perp = 0$. Suppose $u \in U \cap U^\perp$ then u lies in the kernel of $x \mapsto s(x \mid u)$ and hence $s(u \mid u) = 0$ Suppose we had $u \neq 0$, then $0 = s(u \mid u) \in \{ a\varepsilon(a) \mid a \in F^* \} \subseteq F^* = F \setminus \{0\}$. By that contradiction we have $u = 0$.
Next we prove $V = U + U^\perp$. To do this choose a basis $\{ v_1, \ldots, v_r \}$ of U and append it to a basis

$\{ v_1, \ldots, v_r, \ldots, v_n \}$ of V. Using the Gram-Schmidt-algorithm (4.97.(ii)) we can turn this basis into an ONB $\{ g_1, \ldots, g_r, \ldots, g_n \}$ of V with respect to ε. Let

$$\begin{aligned} U &= \mathrm{Lh}\{ v_1, \ldots, v_r \} = \mathrm{Lh}\{ g_1, \ldots, g_r \} \\ U' &:= \mathrm{Lh}\{ g_{r+1}, \ldots, g_n \} \end{aligned}$$

We will now prove that $U' \subseteq U^\perp$: For any $j \in (r+1) \ldots n$ and any $i \in 1 \ldots r$ we have $s(g_j \mid g_i) = 0$. As the g_i generate U this implies $s(g_j \mid u) = 0$ for any $u \in U$ and any $j \in (r+1) \ldots n$. But as the g_j generate U' we have $U' \subseteq U^\perp$.
But it is also clear, that $V = U + U'$, if we consider any $x \in V$, then [as $\{ g_1, \ldots, g_n \}$ is a basis of V] there are coefficients $x_k \in F$ such that x can be written in the form

$$x = \sum_{k=1}^{n} x_k v_k = \sum_{i=1}^{r} x_i v_i + \sum_{j=r+1}^{n} x_j v_j \in U + U'$$

Thus we have $V = U + U' \subseteq U + U^\perp \subseteq V$ and hence $V = U + U^\perp$. But we have already proved $U \cap U^\perp = 0$ such that $V = U \oplus U^\perp$ is the inner direct sum. Applying this argument to $U^\perp$ we find $V = U^\perp \oplus (U^\perp)^\perp$. But as $U^\perp = \mathrm{Lh}\{ g_{r+1}, \ldots, g_n \}$ it follows that $(U^\perp)^\perp = \mathrm{Lh}\{ g_1, \ldots, u_r \} = U$.
Let us finish the proof by showing $U' = U^\perp$: We have already seen $U' \subseteq U^\perp$ and $V = U \oplus U^\perp$ also $V = U \oplus U'$ is clear by the definiton of U'. Thus consider any $x \in U^\perp$ and write $x = u + u' \in U + U'$. Then $u' \subseteq U' \subseteq U^\perp$. But as $x = 0 + x \in U + U^\perp$ and the decompositions in $U \oplus U^\perp$ are unique we have $u = 0$ and $u' = x$. In particular $x = u' \in U'$ such that $U^\perp \subseteq U'$ as well. □

Proof of (4.107):

(i) Clearly $P^\top \leq_{\mathsf{m}} M$ is a sub-module of M, as it is the intersection of kernels of a β-linear map and these are sub-modules. Also it is clear that $P \mapsto P^\top$ is order reversing $P_1 \subseteq P_2 \implies P_2^\top \subseteq P_2^\top$ as $P^\top$ is defined by an intersection over $p \in P$. If now $p \in P$ then for any $x \in P^\top$ we have $b(p, x) = 0$. And as this is true for any $x \in P^\top$ we see $p \in (P^\top)^\perp$ such that $P \subseteq (P^\top)^\perp$. Due to the symmetry of the definition the same is true for $Q \mapsto Q^\perp$. Thus $(P \mapsto P^\top, Q \mapsto Q^\perp)$ satisfies property (b) of a Galois connection.

(ii) Consider some $u, v \in L$ and $x, y \in M$ such that $(u + M^\perp, x + L^\top) = (v + M^\perp, y + L^\top)$. That is $v - u \in M^\perp$ and $y - x \in L^\top$. And by definition this implies $b(v - u, y) = 0$ and $b(u, y - x) = 0$ for any $u \in L$ and any $y \in M$. And thereby we find that $\overline{b}$ truly is well-defined (and the linearity in both arguments is trivial), since

$$\begin{aligned} b(v, y) &= b(v - u, y) + b(u, y) = b(u, y) \\ &= b(u, y - x) + b(u, x) = b(u, x) \end{aligned}$$

Also it is clear, that $\overline{b}$ is non-degenerate: Suppose there was some $u + M^\perp \in L/M^\perp$ such that for any $x + L^\top \in M/L^\top$ we had $0 = \overline{b}(u + M^\perp, x + L^\top) = b(u, x)$, then by definition this means $u \in M^\perp$ and hence $u + M^\perp = 0 \in L/M^\perp$. In complete analogy we also find $(M/L^\top)^\perp = 0$ such that $\overline{b}$ is non-degenerate.

(iii) As for any $i \in I$ we have $P_i \subseteq \sum_i P_i$ and $P \mapsto P^\top$ is order-reversing we already have $(\sum_i P_i)^\top \subseteq$

$P_i^\top$ for any $i \in I$. And this is the "$\subseteq$" part of the equality. For the converse inclusion we consider any $x \in M$ with $x \in \bigcap_i P_i^\top$. This means that for any $i \in I$ and any $p_i \in P_i$ we have $b(p_i, x) = 0$. If now $u \in \sum_i P_i$ is any element of the sum of the P_i then (by definition) there is a finite subset $\Omega \subseteq I$ such that $u = \sum_i p_i$ for some $p_i \in P_i$ where the sum runs over $i \in \Omega$. But then we get

$$b(u,x) \;=\; b\left(\sum_{i\in\Omega} p_i, x\right) \;=\; \sum_{i\in\Omega} b(p_i,x) \;=\; \sum_{i\in\Omega} 0 \;=\; 0$$

That is $b(u,x) = 0$ for any $u \in \sum_i P_i$. But by definition this is nothing but $x \in (\sum_i P_i)^\top$ and thereby $\bigcap_i P_i^\top \subseteq (\sum_i P_i)^\top$ as x has been arbitrary. Due to the symmetry the argument it also is clear, that this is true for any family of sumbodules $(Q_j) \subseteq \mathrm{Subm}(M)$.

(iv) Consider any $0 \neq x \in L$ and any $0 \neq y \in M$. If $a \in \mathrm{ann}(x)$ then $ax = 0$ and hence $0 = b(0,y) = b(ax,y) = \alpha(a)b(x,y) = \beta(a)b(x,y) = b(x,ay)$. As $x \neq 0$ but b is integral this implies $ay = 0$ which is $a \in \mathrm{ann}(y)$ again. Hence we have $\mathrm{ann}(x) \subseteq \mathrm{ann}(y)$ and the equality is clear, due to the symmetry of the argument.

It remains to prove, that $\mathrm{ann}(x) \trianglelefteq_{\mathrm{i}} R$ is a prime ideal. First of all we have $x \neq 0$ such that $1 \notin \mathrm{ann}(x)$ and hence $\mathrm{ann}(x) \neq R$. Now consider any two $a, r \in R$ such that $ar \in \mathrm{ann}(x)$ but $r \notin \mathrm{ann}(x)$, then we have to prove $a \in \mathrm{ann}(x)$: Choose any $0 \neq y \in M$, then $0 = b(0,y) = b(arx,y) = \alpha(a)b(rx,y) = \beta(a)b(rx,y) = b(rx,ay)$. But as $r \notin \mathrm{ann}(x)$ we have $rx \neq 0$ and as b is integral this implies $a \in \mathrm{ann}(y) = \mathrm{ann}(x)$. Therefore $\mathrm{ann}(x) \in \mathrm{Spec}(R)$ is a prime ideal.

□

Proof of (4.101):

(i) First of all $\{ m'_1, \ldots, m'_n \}$ is linearly independent: suppose we have a linear relation (for some $a_i \in R$) between the m'_i of the form

$$\sum_{i=1}^{n} a_i\, m'_i \;=\; 0$$

But from this we get $a_j = 0$ for any $j \in 1 \ldots n$ (which is the linear independence, as desired) by evaluating this at $m_j \in M$

$$0 \;=\; \sum_{i=1}^{n} a_i\, m'_i(m_j) \;=\; \sum_{i=1}^{n} a_i\, \delta_{i,j} \;=\; a_j$$

But this set also generates M': Given any $f \in M'$ we let $f_i := f(m_i)$ (hence $f_i \in R$). For any $x = \sum_i x_i m_i \in M$ we then get

$$f(x) \;= f\left(\sum_{i=1}^{n} x_i\, m_i\right) = \sum_{i=1}^{n} x_i\, f_i \;=\; \sum_{i=1}^{n} f_i\, m'_i(x)$$

As this is true for any $x \in M$ we have $f = \sum_i f_i m'_i$ which is contained in the linear hull of the m'_i. Together $\{ m'_1, \ldots, m'_n \}$ is a basis of M'.

(ii) Consider any $f \in M'$ and expand it as $f = \sum_i f_i m'_i$. Then for any $k \in 1 \ldots n$ we find $\beta(m_k)(f) =$

$m''_k(f)$ by computing

$$\begin{aligned}\beta(m_k)\left(\sum_{i=1}^n f_i m'_i\right) &= \sum_{i=1}^n f_i \beta(m_k)(m'_i) = \sum_{i=1}^n f_i m'_i(m_k)\\ &= \sum_{i=1}^n f_i \delta_{i,k} = \sum_{i=1}^n f_i m''_k(m'_i) = m''_k\left(\sum_{i=1}^n f_i m'_i\right)\end{aligned}$$

(iii) Let us first suppose M is free and pick up a basis $\{ m_i \mid i \in I \}$ of M. For any $j \in I$ let us the define $m'_j \in M'$ as with the dual basis

$$m'_j : M \to R : \sum_{i=1}^n a_i m_i \mapsto a_j$$

Then for any $x = \sum_i x_i m_i$ we get $\beta(x)(m'_j) = m'_j(x) = x_j$. Thus $\beta(x) = 0$ implies $x_j = 0$ for any $j \in I$ which means $x = 0$. And as $\mathrm{kn}(\beta) = 0$ we see that β is injective.

If the basis of M is finite $\{ m_1, \ldots, m_n \}$ then by (i) we can take to the dual basis $\{ m'_1, \ldots, m'_n \}$ which is $m'_j(m_i) = \delta_{i,j}$. Using (i) again we can also look at the dual basis of the dual basis $\{ m''_1, \ldots, m''_n \}$ which is $m''_j(m'_i) = \delta_{i,j}$. But thereby we find $\beta(m_i)(m'_j) = m'_j(m_i) = \delta_{i,j} = m''_i(m'_j)$ such that $\beta(m_i)$ and m''_i agree on $\{ m'_1, \ldots, m'_n \}$. But as this generates M' (it even is a basis) this means $\beta(m_i) = m''_i$ such that $M'' = \mathrm{Lh}\{ m''_1, \ldots, m''_n \} \subseteq \mathrm{im}(\beta) \subseteq M''$. But $\mathrm{im}(\beta) = M''$ is the surjectivity of β that we needed.

(iv) For (a) $\implies$ (c) we start with any $x \in M$ such that $f(x) = 0$ for any $f \in M'$. That is $\beta(x)(f) = f(x) = 0$ for any $f \in M'$ which means $\beta(x) = 0 \in M''$. But as β is injective we have $\mathrm{kn}(\beta) = 0$ such that $x = 0$. For (c) $\implies$ (b) we first note that δ is bilinear (by remark (4.100.(iii))) and hence a duality. Now (c) is property (2) of the dual pair. So we have to prove property (3): for any $f \in M'$ we need the implication $(\forall\, x \in M : f(x) = 0) \implies f = 0$. But this is trivial, $f(x) = 0$ for any $x \in M$ means that $f = 0$ is the zero map. It remains (b) $\implies$ (a): If suffices to show $\mathrm{kn}(\beta) = 0$. Thus consider any $x \in M$ with $\beta(x) = 0$, that is $\beta(x)(f) = 0$ for any $f \in M'$. This is $f(x) = \beta(x)(f) = 0$ such that $x = 0$ by property (2) of (M, M').

(v) Property (1) is identical, but we will prove that in this case (2) and (2') resp. (3) and (3') are equivalent: For property (2) this is plain to see $\forall\, f \in \mathrm{im}(\delta) : f(x) = 0$ is just a reformulation of $\forall\, x \in N : \delta_x(u) = 0$. But as $\delta_x(u) = \delta(u, x)$ this is just property (2) again. Let us turn to the implication (3) $\implies$ (3') next: By assumption we have $\forall\, u \in M : \delta_x(u) = 0 \implies x = 0$. In terms of maps this is $\delta_x = 0 \implies x = 0$. Now suppose we had $\delta_x = \delta_y$ then $0 = \delta_y - \delta_x = \delta_{y-x}$ such that $x - y = 0$ and hence $x = y$. And this is the injectivity of $x \mapsto \delta_x$. Conversely (3') $\implies$ (3): Suppose there was some $x \in N$ such that $\forall\, u \in M : \delta_x(u) = 0$. In terms of maps this is $\delta_x = 0$. But as δ is a duality we have $\delta_0 = 0$ already, so by injectivity we get $x = 0$.

(vi) Clearly $S(y) : x \mapsto s(x \mid y)$ is well-defined, by properties (1) and (2) of a sesqui-linear map. Therefore S is well-defined. Also $y \mapsto S(y)$ is ε-linear, by properties (4) and (5) of a sesqui-linear map. For the injectivity of S we consider any two $y, z \in M$ such that $S(y) = S(z)$. Then $0 = S(z - y)$, that is for any $x \in M$ we have $0 = S(z - y)(x) = s(x \mid z - y)$. In particular for

$x = z - y$ we have $0 = s(x \mid x)$. But as s is poritive definite we have $0 = s(x \mid x) \in R^*$ a contradiction. This means $z - y = 0$ and hence $y = z$ which is the injectivity of S.

For the surjectivity of S we pick up an ONB $\{ g_1, \ldots, g_n \}$ of M according to (4.97.(iii)), which is possible, since M is free and finitely generated. Let $\{ g'_1, \ldots, g'_n \}$ be the respective dual basis. Then we claim $S(g_i) = g'_i$ for any $i \in 1 \ldots n$. To do this consider any $x \in M$, as the g_i are a basis of M we get

$$x \;=\; \sum_{i=1}^{n} x_i g_i \quad \text{where} \quad x_i \;=\; s(x \mid g_j)$$

according to (4.97.(ii)). But by definition of the dual base we also have $g'_i(x) = x_i = s(x \mid g_i) = S(g_i)(x)$. As this is true for any x we see $g'_i = S(g_i)$. As the g'_i generate M' we can write any $f \in M'$ as

$$f \;=\; \sum_{i=1}^{n} f_i g'_i$$

for some $f_i \in R$. As ε is surjective we can choose some $a_i \in R$ such that $\varepsilon(a_i) = f_i$. Then we find the surjectivity of S, as

$$S\left(\sum_{i=1}^{n} a_i g_i \right) \;=\; \sum_{i=1}^{n} \varepsilon(a_i)\, S(g_i) \;=\; \sum_{i=1}^{n} f_i g'_i \;=\; f$$

□

Proof of (4.104):

(i) Let $\mathcal{M} = (m_1, \ldots, m_n)$ be the ONB given and recall that the adjoint endomorphism φ' is determined by the following property, for any $x, y \in M$

$$s\big(\varphi(x) \mid y\big) \;=\; s\big(x \mid \varphi'(y)\big)$$

We specifically chose $x = m_i$ and $y = m_k$ for any $i, k \in 1 \ldots n$, then - by construction of the matrix representation - we find the entries of A and A', since

$$\begin{aligned} s\big(\varphi(m_i) \mid m_k\big) \;&=\; s\left(\sum_{j=1}^{n} [A]_{i,j} m_j \mid m_k \right) \;=\; \sum_{j=1}^{n} [A]_{i,j}\, s\big(m_j \mid m_k\big) \;=\; [A]_{i,k} \\ s\big(m_i \mid \varphi'(m_k)\big) \;&=\; s\left(m_i \mid \sum_{j=1}^{n} [A']_{k,j} m_j \right) \;=\; \sum_{j=1}^{n} \varepsilon\big([A']_{k,j}\big) s\big(m_i \mid m_j\big) \;=\; \varepsilon\big([A']_{k,i}\big) \end{aligned}$$

As these are identical, that is $[A^*]_{k,i} = [A]_{i,k} = \varepsilon([A']_{k,i})$ for any $i, k \in 1 \ldots n$ such that $A^* = \varepsilon(A')$. In other words, as ε is invertible, we have $A' = \varepsilon^{-1}(A^*)$, as claimed.

(ii) The implication (a) $\implies$ (b) has already been proved in (4.103.(iii)). And for (b) $\implies$ (c) we recall, that M is a finitely generated free R-module, that is M has a basis $\{ m_1, \ldots, m_n \}$. By Gram-Schmidt-Orthonormalsation (4.97.(iii)) we find an ONB $\{ g_1, \ldots, g_n \}$ of M. Apply any order to this set and call the ordered ONB $\mathcal{G}$. Then (b) provides $A^* = \varepsilon(A)$ for this ONB and hence we have (c). Finally for (c) $\implies$ (a) we have to prove $\varphi' = \varphi$. Yet by (i) we know $A' = \varepsilon^{-1}(A^*)$ and

by assumption $A^* = \varepsilon(A)$ this is

$$A' \;=\; \varepsilon^{-1}\big(A^*\big) \;=\; \varepsilon^{-1}\big(\varepsilon(A)\big) \;=\; A$$

That is $A' = A$ and as $\varphi \mapsto A = [\varphi]_{\mathcal{M}}$ is an isomorphism of R-algebras, this implies $\varphi' = \varphi$. Hence we have come full-circle.

(iii) For (a) $\implies$ (b) we have $\varphi'\varphi = \varphi\varphi'$ and are given any ordered ONB $\mathcal{M}$ of M. As $\varphi \mapsto A = [\varphi]_{\mathcal{M}}$ is an R-algebra isomorphism, using (i) we immediately get

$$\begin{aligned}\big[\varphi'\varphi\big] \;&=\; [\varphi'][\varphi] \;=\; \varepsilon^{-1}\big(A^*\big)\, A\\ \big[\varphi\varphi'\big] \;&=\; [\varphi][\varphi'] \;=\; A\,\varepsilon^{-1}\big(A^*\big)\end{aligned}$$

As $[\varphi'\varphi] = [\varphi\varphi']$ are identical, by (a), we find the identity of the matrices claimed in (b), too. As in (ii) above, (b) implies (c), as there is an (ordered) ONB of M. As for (c) $\implies$ (a), This is just the reverse direction of (a) $\implies$ (b): We can conclude $\varphi'\varphi = \varphi\varphi'$ from the identity of the matrices.

□

Proof of (4.103):

(ii) Suppose $\mathcal{M} = \big\{\, m_1, \ldots, m_p \,\big\}$ is an ONB of M, that is $\mathcal{M}$ is a basis of M such that satisfies $s(m_i, m_j) = \delta_{i,j}$. There is such a basis, since s is positive definite and hence we may use Gram-Schmidt (4.97). Thus if $u \in M^\perp$ then we consider the representation $u = \sum_i u_i m_i$ in this basis and compute

$$0 \;=\; s\big(u \mid m_j\big) \;=\; s\left(\sum_{i=1}^{p} u_i m_i \mid m_j\right) \;=\; \sum_{i=1}^{p} u_i s\big(m_i \mid m_j\big) \;=\; u_j$$

Hence $u \in M^\perp$ implies $u = 0$ and this is $M^\perp = 0$. The same is true for t and hence $N^\perp = 0$, as well.

(i) Clearly $N := R^n$ has the ONB $\big\{\, e_1, \ldots, e_n \,\big\}$ with respect to b_n. That is we have $b_n(e_i, e_j) = \delta_{i,j}$ and hence my use (ii) to find $(R^n)^\perp = 0$ and likewise $(R^m)^\perp = 0$. Then we compute

$$\begin{aligned}\big(\operatorname{im}(A)\big)^\perp \;&=\; \big\{\, u \in R^m \mid \forall\, v \in \operatorname{im}(A) \;:\; \langle u, v\rangle \;=\; 0 \,\big\}\\ &=\; \big\{\, u \in R^m \mid \forall\, y \in R^n \;:\; \langle u, Ay\rangle \;=\; 0 \,\big\}\\ &=\; \big\{\, u \in R^m \mid \forall\, y \in R^n \;:\; \langle A^*u, y\rangle \;=\; 0 \,\big\}\\ &=\; \Big\{\, u \in R^m \mid A^*u \;\in\; \big(R^n\big)^\perp \;=\; 0 \,\Big\} \;=\; \operatorname{kn}\big(A^*\big)\\ \big(\operatorname{im}(A^*)\big)^\perp \;&=\; \big\{\, x \in R^n \mid \forall\, y \in \operatorname{im}(A^*) \;:\; \langle x, y\rangle \;=\; 0 \,\big\}\\ &=\; \big\{\, x \in R^n \mid \forall\, v \in R^m \;:\; \langle x, A^*v\rangle \;=\; 0 \,\big\}\\ &=\; \big\{\, x \in R^n \mid \forall\, v \in R^m \;:\; \langle Ax, v\rangle \;=\; 0 \,\big\}\\ &=\; \Big\{\, x \in R^n \mid Ax \;\in\; \big(R^m\big)^\perp \;=\; 0 \,\Big\} \;=\; \operatorname{kn}\big(A\big)\end{aligned}$$

(iii) Choose ordered ONB $\mathcal{M} = (m_1, \ldots, m_p)$ of M with respect to s and $\mathcal{N} = (n_1, \ldots, n_q)$ of N with respect to t again. And denote the basis representation of φ with respect to these bases by

$A = (a_{j,i}) := [\varphi] \in \mathrm{mat}_{q,p}(R)$, that is $\varphi(m_i) = \sum_j a_{j,i}\, n_j$. Now define $A' = (a'_{i,j}) \in \mathrm{mat}_{p,q}(R)$ by $a'_{i,j} := \varepsilon^{-1}(a_{j,i})$. That is $A' = \varepsilon^{-1}(A^*)$. Then we define $\varphi' : N \to M$ to be the homomorphism which has the representation $A' = [\varphi']$ in these bases, that is $\varphi'(n_j) = \sum_i a'_{i,j}\, m_i$. We claim that φ' is the (one and only) adjoint of φ. That is, given any $u \in M$ and $y \in N$ we need to show $s(u \mid \varphi'(y)) = t(\varphi(u) \mid y)$. If we also represent $[u] = (u_1, \ldots, u_p) \in R^p$ and $[y] = (y_1, \ldots, y_q) \in R^q$ in the respective basis that this boils down to a straightforward computation:

$$\begin{aligned}
s\big(u \mid \varphi'(y)\big) &= s\left(\sum_{i=1}^{p} u_i m_i \mid \sum_{j=1}^{q} y_j \varphi'(n_j)\right) \\
&= \sum_{i=1}^{p}\sum_{j=1}^{q} u_i \varepsilon(y_j)\, s\left(m_i \mid \varphi'(n_j)\right) \\
&= \sum_{i=1}^{p}\sum_{j=1}^{q} u_i \varepsilon(y_j)\, s\left(m_i \mid \sum_{k=1}^{p} a'_{j,k} m_k\right) \\
&= \sum_{i=1}^{p}\sum_{j=1}^{q} u_i \varepsilon(y_j) \sum_{k=1}^{p} \varepsilon(a'_{j,k})\, s(m_i \mid m_k) \\
&= \sum_{i=1}^{p}\sum_{j=1}^{q} u_i \varepsilon(y_j) \sum_{k=1}^{p} \varepsilon\varepsilon^{-1}(a_{k,j})\delta_{i,k} \\
&= \sum_{i=1}^{p}\sum_{j=1}^{q} u_i \varepsilon(y_j) a_{i,j} \\
t\big(\varphi(u) \mid y\big) &= t\left(\sum_{i=1}^{p} u_i \varphi(m_i) \mid \sum_{j=1}^{q} y_j n_j\right) \\
&= \sum_{i=1}^{p}\sum_{j=1}^{q} u_i \varepsilon(y_j)\, t\left(\varphi(m_i) \mid n_j\right) \\
&= \sum_{i=1}^{p}\sum_{j=1}^{q} u_i \varepsilon(y_j)\, t\left(\sum_{k=1}^{q} a_{i,k} n_k \mid n_j\right) \\
&= \sum_{i=1}^{p}\sum_{j=1}^{q} u_i \varepsilon(y_j) \sum_{k=1}^{q} a_{i,k}\, t\left(n_k \mid n_j\right) \\
&= \sum_{i=1}^{p}\sum_{j=1}^{q} u_i \varepsilon(y_j) \sum_{k=1}^{q} a_{i,k}\delta_{k,j} \\
&= \sum_{i=1}^{p}\sum_{j=1}^{q} u_i \varepsilon(y_j) a_{i,j} \\
&= s\big(u \mid \varphi'(y)\big)
\end{aligned}$$

(iii) If φ' is the adjoint homomorphism of φ then by definition we have $t(\varphi(u) \mid y) = s(u \mid \varphi'(y))$. But as both s and t are sesqui-linear forms with respect to ε (the positive definiteness of s or t is not needed)

$$t\big(x \mid \varphi(v)\big) \;=\; \varepsilon\left(t\big(\varphi(v) \mid x\big)\right) \;=\; \varepsilon\left(s\big(v \mid \varphi'(x)\big)\right) \;=\; s\big(\varphi'(x) \mid v\big)$$

(iv) Note that by (ii) we have $M^\perp = 0$ and $N^\perp = 0$. Also note that φ' satisfies both identities of (iii)

Then we simply use the same computation as in (i) before:

$$\begin{aligned}
\big(\mathrm{im}\,(\varphi)\,\big)^{\perp} &= \{\, x \in N \mid \forall\, y \in \mathrm{im}(\varphi) \;:\; t(x \mid y) \,=\, 0 \,\} \\
&= \{\, x \in N \mid \forall\, v \in M \;:\; t(x \mid \varphi(v)) \,=\, 0 \,\} \\
&= \big\{\, x \in N \mid \forall\, v \in M \;:\; s(\varphi'(x) \mid v) \,=\, 0 \,\big\} \\
&= \Big\{\, x \in N \mid \varphi'(x) \,\in\, M^{\perp} \,=\, 0 \,\Big\} \,=\, \mathrm{kn}\big(\varphi'\big) \\
\big(\mathrm{im}\,(A^*)\,\big)^{\perp} &= \big\{\, u \in M \mid \forall\, v \in \mathrm{im}(\varphi') \;:\; s(u \mid v) \,=\, 0 \,\big\} \\
&= \big\{\, u \in M \mid \forall\, y \in N \;:\; s(u \mid \varphi'(y)) \,=\, 0 \,\big\} \\
&= \{\, u \in M \mid \forall\, y \in N \;:\; t(\varphi(u) \mid y) \,=\, 0 \,\} \\
&= \Big\{\, u \in M \mid \varphi(u) \,\in\, \big(N\big)^{\perp} \,=\, 0 \,\Big\} \,=\, \mathrm{kn}\big(\varphi\big)
\end{aligned}$$

□

Proof of (4.110):
The isomorphy of the dual space $(M \oplus N)'$ is just a special case of (3.37). Nevertheless we will give a proof here: First note, that $\pi_M \iota_M : x \mapsto x$ is the identity, whereas $\pi_N \iota_M : x \mapsto 0$ is the zero-map. We also find the following map $\iota_M \pi_M : (x,y) \mapsto (x,0)$. If we start with $h \in (M \oplus N)'$ then

$$h \;\mapsto\; \big(h\iota_M, h\iota_N\big) \;\mapsto\; h\iota_M\pi_M + h\iota_N\pi_N$$

But $h(x,y) = h(x,0) + h(0,y)$, as h is R-linear, so this is h again. Conversely if we start with $(f,g) \in M' \oplus N'$ then this is mapped to

$$(f,g) \;\mapsto\; h := f\pi_M + g\pi_N \;\mapsto\; \big(h\iota_M, h\iota_N\big)$$

Hereby $h\iota_M = f\pi_M\iota_M + g\pi_N\iota_M = f\mathbb{1}_M + g\,0 = f$ and likewise $h\iota_N = g$ again. Thus we have seen that these maps truly are mutually inverse.
Now we turn to the isomorphy of the bidual $(M \oplus N)''$. If we start with $\omega \in (M \oplus N)''$ then this element is mapped to

$$\omega \;\mapsto\; (\omega_M, \omega_N) \;\mapsto\; \big(h \mapsto \omega_M\big(h\iota_M\big) + \omega_N\big(h\iota_N\big)\big)$$

where $\omega_M(f) = \omega(f\pi_M)$ and $\omega_N(g) = \omega(g\pi_N)$. For $f = h\iota_M$ this is $\omega_M(f) = \omega(h\iota_M\pi_M)$ where $h\iota_M\pi_M(x,y) = h(x,0)$. Likewise $h\iota_N\pi_N(x,y) = h(0,y)$ such that the sum of these is $h(x,y)$. This means $h = \omega_M(h\iota_M) + \omega_N(h\iota_N)$ which is the first part. For the second part we start with $\omega_M \in M''$ and $\omega_N \in N''$ such that (ω_M, ω_N) is mapped to ω with

$$\omega(h) \;=\; \omega_M\big(h\iota_M\big) + \omega_N\big(h\iota_N\big)$$

In turn ω is mapped to $f \mapsto \omega(f\pi_M)$ and $g \mapsto \omega(g\pi_N)$ separately. So we need to show $\omega(f\pi_M) = \omega_M(f)$ and $\omega(g\pi_N) = \omega_N(g)$. But watch what ω does to $f\pi_M$

$$\omega\big(f\pi_M\big) \;=\; \omega_M\big(f\pi_M\iota_M\big) + \omega_N\big(f\pi_M\iota_N\big) \;=\; \omega_M(f) + \omega_N(0) \;=\; \omega_M(f)$$

Similarly we find $\omega(g\pi_N) = \omega_N(g)$ such that $(\omega_M, \omega_N) \mapsto \omega \mapsto (\omega_M, \omega_N)$ closes the circle. Together

we have shown the isomorphy of the bidual.
It remains to prove the commutativity of the diagram, that is for any $(x,y) \in M \oplus N$ we need to show $\Theta\beta(x,y) = (\beta_M(x), \beta_N(y))$. Let us abbreviate $\omega := \beta(x,y)$, $\omega_M := \beta_M(x)$ and $\omega_N := \beta_N(y)$, then we need to show $\Theta(\omega) = \omega_M \times \omega_N$. By definition of Θ the M-part of this is $\omega(f\pi_M) = \omega_M(f)$ for any $x \in M$. But then

$$\begin{aligned} \omega(f\pi_M) &= \beta(x,y)(f\pi_M) = f\pi_M(x,y) = f(x) \\ \omega_M(f) &= \beta_M(x)(f) = f(x) \end{aligned}$$

which is $\omega(f\pi_M) = \omega_M(f)$ as needed. Likewise we see $\omega(g\pi_N) = \omega_N(g)$ for any $g \in N'$ which seals the commutativity of the diagram. □

Proof of (4.109):

(i) Consider any $f = \sum_j b_j m'_j \in M'$ and any $p = \sum_i p_i a_i m_i \in P$. Then it is clear, that $f(m_i) = \sum_j b_j m'_j(m_i) = b_i$ and thereby

$$f(p) = \sum_{i=1}^{r} p_i a_i f(m_i) = \sum_{i=1}^{r} p_i a_i b_i$$

Thus if $f \in P^\top$ then $f(p) = 0$ for any $p \in P$ and thereby $a_i bi = 0$ for any $i \in 1 \ldots r$. But as R is an integral domain and $a_i \neq 0$ this implies $b_i = 0$ such that $f \in \mathrm{Lh}\{ m'_{r+1}, \ldots, m'_n \}$. Conversely if $f \in \mathrm{Lh}\{ m'_{r+1}, \ldots, m'_n \}$ then for the same reasoning we have $f(p) = 0$ for any $p \in P$ and hence $f \in P^\top$. Thus we have proved

$$P^\top = \delta(P \mid \perp) = \mathrm{Lh}\{ m'_{r+1}, \ldots, m'_n \}$$

Let us now take a look at $P^{\top\perp} = \delta(\perp \mid P^\top)$ which is defined to be $P^{\top\perp} = \{ x \in M \mid \forall f \in P^\top : f(x) = 0 \}$. If now $f = \sum_j b_j m'_j \in P^\top$ and $x = \sum_k x_k m_k \in M$ then in complete analogy we have

$$f(x) = \sum_{k=1}^{n} x_k f(m_k) = \sum_{j=r+1}^{n} x_j b_j$$

Thus if $x \in \mathrm{Lh}\{ m_1, \ldots, m_r \}$ then $f(x) = 0$ for any $f \in P^\top$ and hence $x \in P^{\top\perp}$. Conversely if $f(x) = 0$ for any $f \in P^{\top\perp}$ then necessarily $x_j = 0$ for any $j \in (r+1) \ldots n$ and hence $x \in \mathrm{Lh}\{ m_1, \ldots, m_r \}$. Thus we also have

$$P^{\top\perp} = \delta(\perp \mid P^\top) = \mathrm{Lh}\{ m_1, \ldots, m_r \}$$

And $\mathrm{Lh}\{ m_1, \ldots, m_r \} = \mathrm{Hull}(P)$ is obvious: By definition any $a_i m_i$ is contained in $\mathrm{Hull}(P)$ (for $i \in 1 \ldots r$) and as these generate P we have $\mathrm{Lh}\{ m_1, \ldots, m_r \} \subseteq \mathrm{Hull}(P)$. Conversely if $x = \sum_k x_k m_k \in M$ such that $ax \in P$ for some $a \in R \setminus \{0\}$, then

$$ax = \sum_{k=1}^{n} a x_k m_k \in P = \mathrm{Lh}\{ a_1 m_1, \ldots, a_r m_r \}$$

As the m_k are a basis of M we may compare coefficients and find $a_i \mid ax_i$ for any $i \in 1 \ldots r$ and

$ax_j = 0$ for $j \in (r+1)\ldots n$. As R is an integral domain and $a \neq 0$ this means $x_j = 0$ and hence $x \in \mathsf{Lh}\{\, m_1, \ldots, m_r \,\}$. Thus we have finally established

$$\mathsf{Lh}\{\, m_1, \ldots, m_r \,\} \;=\; \mathsf{Hull}(P)$$

(ii) As P is a vector space over a field (3.65) tells us, that P is free. Let $\{\, m_1, \ldots, m_r \,\}$ be a basis of P. By (3.64.(v)) we can extend this to a basis $\{\, m_1, \ldots, m_n \,\}$ of M. The identities of $P^\top$ and $P^{\top\perp}$ are just a special case of (i), then.

(iii) Since M is free and finitely generated the natural map $\beta : M \to M''$ is an isomorphism, according to (4.101.(iii)). In particular we have $\beta(M) = M''$ and by definition $x''(f) = f(x)$ for any $x \in M$ and $f \in M'$. But thereby we can just compute

$$\begin{aligned} F^\top &= \{\, \omega \in M'' \mid \forall\, f \in F \,:\, \omega(f) = 0 \,\} \\ &= \{\, x'' \in \beta(M) \mid \forall\, f \in F \,:\, x''(f) = 0 \,\} \\ &= \beta\left(\{\, x \in M \mid \forall\, f \in F \,:\, f(x) = 0 \,\}\right) \\ &= \beta\big(F^\perp\big) \end{aligned}$$

Likewise for $P \leq_{\mathsf{m}} M$ any $\omega \in \beta(P)$ is of the form $\omega = x''$ for some $x \in P$ and thereby $\omega(f) = x''(f) = f(x)$. Thus we find

$$\begin{aligned} \beta(P)^\perp &= \{\, f \in M' \mid \forall\, \omega \in \beta(P) \,:\, \omega(f) = 0 \,\} \\ &= \{\, f \in M' \mid \forall\, x \in P \,:\, f(x) = 0 \,\} \;=\; P^\top \end{aligned}$$

(iv) The implication (a) $\Longrightarrow$ (b) is clear: Just let $Q := \mathsf{Lh}\{\, m_{r+1}, \ldots, m_n \,\}$ then it is clear that $M = P \oplus Q$. For (b) $\Longrightarrow$ (d) we are given $x \in \mathsf{Hull}(P)$, that is $ax \in P$ for some $\in R$ with $a \neq 0$. Write out $x = p + q$ for some $p \in P$ and $q \in Q$, then $ax = ap + aq \in P$. As $M = P \oplus Q$ this means $aq = 0$. But as R is an integral domain (even a PID) and M is free, M also is torsion-free. Thus $aq = 0$ and $a \neq 0$ imply $q = 0$ such that $x = p + q = p \in P$. Thus we have proved $\mathsf{Hull}(P) \subseteq P$ and the converse inclusion is generally true. For the implication (d) $\Longrightarrow$ (e) we note that by assumption and (i) we have $P = \mathsf{Hull}(P) = P^{\top\perp}$. And (e) $\Longrightarrow$ (c) is trivial, as we may just take $F := P^\top \leq_{\mathsf{m}} M'$. It only remains to prove (c) $\Longrightarrow$ (a): So by assumption we have

$$P \;=\; F^\perp \;=\; \{\, x \in M \mid \forall\, f \in F \,:\, f(x) = 0 \,\}$$

Since M is free and finitely generated M' is such, as well, by (4.101.(i)). Since R is a PID (5.28.(iv)) tells us that there are a basis $\{\, f_1, \ldots, f_n \,\}$ of M' and factors $a_1, \ldots, a_r \in R$ such that $\{\, a_1 f_1, \ldots, a_r f_r \,\}$ is a basis of F. Then by (i) we get

$$\begin{aligned} F^\top &= \{\, \omega \in M'' \mid \forall\, f \in F \,:\, \omega(f) = 0 \,\} \\ &= \mathsf{Lh}\{\, f'_{r+1}, \ldots, f'_n \,\} \end{aligned}$$

Again the natural map $\beta : M \xrightarrow{\sim} M''$ is an isomorphism, by (4.101.(iii)). Thus we may take $m_k := \beta^{-1}(f'_k) \in M$ that is $f'_k = m''_k$ for any $k \in 1\ldots n$. Then $\{\, m_1, \ldots, m_n \,\}$ is a basis of M and

by (iii)

$$\begin{aligned}\beta(P) &= \beta\big(F^{\perp}\big) = F^{\top}\\ &= \mathsf{Lh}\{\, f'_{r+1},\ldots,f'_n \,\}\\ &= \mathsf{Lh}\{\, \beta(m_{r+1}),\ldots,\beta(m_n) \,\}\\ &= \beta\big(\mathsf{Lh}\{\, m_{r+1},\ldots,m_n \,\}\big)\end{aligned}$$

As β is injective (even an isomorphism) this implies the equality of $P = \mathsf{Lh}\{\, m_{r+1},\ldots,m_n \,\}$. So by renumbering the basis $\{\, m_1,\ldots,m_n \,\}$ of M we have proved the claim of (a).

(v) For an arbitrary commutative ring we have seen the Galois connection between the sub-modules of M and M' as a special case of (4.107.(i)). And by (0.22) it is a general truth of Galois connections that these interlock the images of the respective maps, that is

$$\begin{array}{ccc}\mathsf{Orc}(M) & \longleftrightarrow & \mathsf{Orc}(M')\\ P & \mapsto & P^{\top}\\ F^{\perp} & \hookleftarrow & F\end{array}$$

where $\mathsf{Orc}(M) := \big\{\, F^{\perp} \mid F \leq_{\mathfrak{m}} M' \,\big\} \subseteq \mathsf{Subm}(M)$ and $\mathsf{Orc}(M') := \big\{\, P^{\top} \mid P \leq_{\mathfrak{m}} M \,\big\} \subseteq \mathsf{Subm}(M')$. But in (iv) we have seen, that $P \in \mathsf{Orc}(M)$ is equivalent to P being a complemented sub-module

$$\mathsf{Orc}(M) = \mathsf{Subc}(M)$$

But as M' is a finitely generated module over a PID R, as well, we can also apply (iv) to a sub-module $F \leq_{\mathfrak{m}} M'$ of M'. That is F is a complemented sub-module of M' if and only if $F = \Omega^{\perp}$ for some $\Omega \leq_{\mathfrak{m}} M''$. But letting $P := \beta^{-1}(\Omega)$ this is $\Omega^{\perp} = \beta(P)^{\perp} = P^{\top}$ due to (iii). Thus we see that $F \in \mathsf{Subc}(M')$ is equivalent to $F \in \mathsf{Orc}(M')$ and thereby we also have

$$\mathsf{Orc}(M') = \mathsf{Subc}(M')$$

□

Proof of (4.111):

(i) Note that $\Theta\beta = \beta_M \times \beta_N$ for some bijective map Θ according to (4.110). Thus if both β_M and β_N are injective then β has to be, as well. Conversely, if β is injective then $\Theta\beta$ is injective, as well and this means both β_M and β_N are injective.

Likewise if β_M and β_N are surjective, then $\beta = \Theta^{-1}(\beta_M \times \beta_N)$ is surjective as well. And if β is surjective then $\Theta\beta$ is surjective, as well and this means both β_M and β_N are surjective.

(ii) This is just a special case of (i): $M \oplus N$ was called *reflexive* iff the natural map β is bijective. And by (i) this is equivalent to β_M and β_N being bijective. But this is when we say M and N are reflexive.

(iii) If P is projective, then there is another R-module Q and a free R-module F such that $F = P \oplus Q$. Since F is free we know that β_F is injective, due to (4.101.(ii)). But then β_P is injective, as well,

according to (i).

Likewise if P if projective and finitely generated, then F can be taken to be finitely generated, too by (??). Thus (4.101.(ii)) tells us, that β_F even is bijective, such that β_P is bijective, by (i). An this means that P is reflexive.

□

Proof of (4.120):

(i) Let us first prove that $\mathrm{Ch}(X)$ is convex: Consider any $x = \sum_i a_i x_i$ and $y = \sum_j b_j y_j$ in $\mathrm{Ch}(X)$. That is x_i and $y_j \in X$ and a_i, $b_j \in \mathbb{R}^+$ where $\sum_i a_i = 1$ and $\sum_j b_j = 1$. If we are now given any a, $b \in \mathbb{R}^+$ such that $a + b = 1$, then

$$ax + by \;=\; \sum_{i=1}^{m} aa_i x_i + \sum_{j=1}^{n} bb_j y_j$$

Thereby aa_i and $bb_j \in \mathbb{R}^+$ and we find that the arbitrary element $ax + by$ of the line segment is contained in $\mathrm{Ch}(X)$ again, since

$$\sum_{i=1}^{m} aa_i + \sum_{j=1}^{n} bb_j \;=\; a\sum_{i=1}^{m} a_i + b\sum_{j=1}^{n} b_j \;=\; a + b \;=\; 1$$

If now $x \in X$ is any fixed element, then we need to prove the identity for $\mathrm{Ch}(X)$. Given $a_k \in \mathbb{R}^+$ with $\sum_k a_k \leq 1$ we let $a_0 := 1 - \sum_k a_k \geq 0$ and $x_0 := x$, then we see that

$$\begin{aligned} x + \sum_{k=1}^{n} a_k(x_k - x) \;&=\; \left(1 - \sum_{k=1}^{n} a_k\right) x + \sum_{k=1}^{n} a_k x_k \\ &=\; a_0 x_0 + \sum_{k=1}^{n} a_k x_k \;\in\; \mathrm{Ch}(X) \end{aligned}$$

is contained in $\mathrm{Ch}(X)$. Conversely consider $z = \sum_k a_k x_k \in \mathrm{Ch}(X)$, that is $\sum_k a_k = 1$. If $x \notin \{x_1, \ldots, x_n\}$ then we find

$$z \;=\; x - \left(\sum_{k=1}^{n} a_k\right) x + \sum_{k=1}^{n} a_k x_k \;=\; x + \sum_{k=1}^{n} a_k(x_k - x)$$

And if $x \in \{x_1, \ldots, x_n\}$ then we may assume $x = x_1$ without loss of generality. And thereby we find another representation of z of the form desired

$$\begin{aligned} z \;&=\; a_1 x + \sum_{k=2}^{n} a_k x_k \\ &=\; a_1 x + \sum_{k=2}^{n} a_k(x_k - x) + \sum_{k=2}^{n} a_k x \\ &=\; \left(\sum_{k=1}^{n} a_k\right) x + \sum_{k=2}^{n} a_k(x_k - x) \\ &=\; x + \sum_{k=2}^{n} a_k(x_k - x) \end{aligned}$$

(ii) Consider any $x, y \in \bigcap_i C_i$ and any $a, b \in \mathbb{R}^+$ such that $a + b = 1$. As $x, y \in C_i$ and C_i is convex, we find $ax + by \in C_i$. But as this is true for any $i \in I$ we have $ax + by \in \bigcap_i C_i$ again.

(iii) The inclusion "$\subseteq$" is easy to see: Of course we have $X \subseteq \mathrm{Ch}(X)$, as for any $x \in X$ we have $x = 1\dot{x} \in \mathrm{Ch}(X)$. But by (i) we also know that $\mathrm{Ch}(X)$ is convex. Thus $C = \mathrm{Ch}(X)$ meets the conditions of the set on the left hand side and hence we have "$\subseteq$".

For the converse inclusion "$\supseteq$" we need to show $\mathrm{Ch}(X) \subseteq C$ for any convex subset $C \subseteq V$ with $X \subseteq C$. Thus consider any $z = \sum_k a_k x_k \in \mathrm{Ch}(X)$, then we will prove $z \in C$ by induction on n: In case $n = 1$ we have $z = a_1 x_1$ for some $a_1 = 1$ and $x_1 \in X$, that is $z = x_1 \in X \subseteq C$. For the induction step $n + 1$ we first note that a_{n+1} would mean $z = a_{n+1} x_{n+1}$ so we are done by the case $n = 1$ already. Next suppose we had $a_{n+1} = 0$. Then we could omit x_{n+1} in $z = a_1 x_1 + \ldots a_n x_n + a_{n+1} x_{n+1}$ such that the sum would run over the first n elements only and we can already use the induction hypothesis to find $z = a_1 x_1 + \ldots a_n x_n \in C$. Thus we may assume $b := a_{n+1} > 0$ and let $a := a_1 + \cdots + a_n$. Then $0 < a = 1 - b < 1$ and therefore we may define $y := x_{n+1}$ and

$$x \;:=\; \sum_{k=1}^{n} \frac{a_k}{a} x_k \;\in\; V$$

As $\sum_k a_k/a = (\sum_k a_k)/a = a/a = 1$ we have $x \in \mathrm{Ch}(X)$ and thereby $x \in C$ by induction hypothesis. Also $y \in X \subseteq C$ by assumption on C. But as C is a convex set and $a + b = 1$ this implies $ax + by \in C$ again. But it is clear that this is z

$$ax + by \;=\; a \sum_{k=1} \frac{a_k}{a} x_k + a_{n+1} x_{n+1} \;=\; \sum_{k=1}^{n+1} \frac{a_k}{a} x_k \;=\; z$$

□

Proof of (4.122):

(i) As $\mathbb{F}$ is a field and the scalar, resp. inner product is a positive definite sesqui-linear form on $\mathbb{F}^n$ we can choose an ONB of $\mathbb{F}^n$ with $U = \mathrm{Lh}\{ g_1, \ldots, g_r \}$ according to (4.98). If now $u \in U$ is any point in U, then we have a basis representation

$$u \;=\; \sum_{k=1}^{r} c_k g_k \;\in\; U$$

We now wish to find the $u \in U$ such that the distance $\| u - x \|$ is minimal. But as the square $\mathbb{R}^+ \to \mathbb{R}^+ : a \mapsto a^2$ preserves order (that is $a < b \iff a^2 < b^2$ it suffices to minimize the following function

$$d(u) \;:=\; \|u - x\|^2$$

As $\mathbb{R} \subseteq \mathbb{C}$ and the inner product agrees with the scalar product for real vectors it suffices to regard $\mathbb{F} = \mathbb{C}$ only. Then

$$\begin{aligned} d(u) &= \langle u - x \mid u - x \rangle \;=\; \langle u \mid u \rangle - \langle u \mid x \rangle - \langle x \mid u \rangle + \langle x \mid x \rangle \\ &= \langle u \mid u \rangle - \big(\overline{\langle x \mid u \rangle} + \langle x \mid u \rangle \big) + \langle x \mid x \rangle \\ &= \langle u \mid u \rangle - 2\mathrm{re}\big(\langle x \mid u \rangle \big) + \langle x \mid x \rangle \end{aligned}$$

Now let $c_k = a_k + ib_k$ and $w_k = u_k + iv_k = \langle x \mid u\rangle$, then we can continue to evaluate this expression by parts

$$\begin{aligned}
\langle u \mid u\rangle &= \langle \sum_{j=1}^{r} c_j g_j \mid \sum_{k=1}^{r} c_k g_k\rangle \\
&= \sum_{j=1}^{r}\sum_{k=1}^{r} c_j \overline{c}_k \langle g_j \mid g_k\rangle \\
&= \sum_{k=1}^{r} c_k \overline{c}_k \;=\; \sum_{k=1}^{r} \left(a_k^2 + b_k^2\right) \\
\langle x \mid u\rangle &= \langle x \mid \sum_{k=1}^{r} c_k g_k\rangle \;=\; \sum_{k=1}^{r} \overline{c}_k \langle x \mid g_k\rangle \;=\; \sum_{k=1}^{r} \overline{c}_k w_k \\
&= \sum_{k=1}^{r} \left(a_k u_k + b_k v_k + i a_k v_k - i b_k u_k\right)
\end{aligned}$$

Thus if we aggregate $a = (a_1, \ldots, a_r)$ resp. $b = (b_1, \ldots, b_r) \in \mathbb{R}^r$ then $d(u) = d(a, b)$ really is a function of the form $d : \mathbb{R}^{2r} \to \mathbb{R}$

$$d(a,b) \;=\; \sum_{k=1}^{r} \left(a_k^2 + b_k^2\right) - 2\sum_{k=1}^{r} \left(a_k u_k + b_k v_k\right) + \|x\|^2$$

In fact d is a quadratic form so it has a uniquely determined minimum, but let us apply some calculus: If (a, b) is a minimum then all the partial derivatives vanish e.g. [Barner, Flohr, Analysis II, Kapitel 14.4]

$$\begin{aligned}
0 \;=\; \frac{\partial}{\partial a_j} f &= -2u_j + 2a_j \\
0 \;=\; \frac{\partial}{\partial b_j} f &= -2v_j + 2b_j
\end{aligned}$$

That is $c_j = a_j + ib_j = u_j + iv_j = w_j = \langle x \mid g_j\rangle$ which means, that the point $u \in U$ of least distance to x has the coefficients $c_k = \langle x \mid g_j\rangle$. In particular it is uniquely determined. And it truly is a minimum, as the Hesse matrix of d is $2 \cdot \mathbb{1}_{2r}$ which is positive definite.

(ii) We need to find the minimum of the function $S \to \mathbb{R}^+ : t \mapsto \| t - x \|$. But as $S = s + U$ where $U = S - s \;\leq_{\mathrm{v}}\; \mathbb{F}^n$ is a subspace of $\mathbb{F}^n$ we can reformulate this to find the minimum of the function

$$d(u) \;=\; \|(s + u) - x\|^2 \;=\; \|(u - (x - s)\|^2$$

where $u \in U$. In (i) we have seen that the point $q \in U$ for which this distance is minimal has the coefficients $c_k = \langle x - s \mid g_k\rangle$, that is

$$q \;=\; \sum_{k=1}^{r} \langle x - s \mid g_k\rangle\, g_k \;\in\; U$$

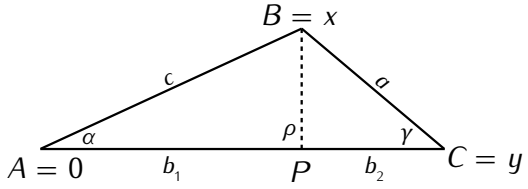
Thus $p = s + q$ is the point in S that minimizes $\|t - x\|$ for $t \in S$. In other words: $p = s + u$ is the orthogonal projection of x to S.

(iii) This is just the special case $r = 1$ of (ii): Since $u \neq 0$ we may define $g := u/\|u\|$. Then clearly $\langle g \mid g \rangle = 1$ such that $\{ g \}$ is an ONB of $U = S - s = \mathbb{F}u$. And hence we find

$$p \;=\; s + \langle x - s \mid g \rangle\, g \;=\; s + \langle x - s \mid \frac{u}{\|u\|} \rangle\, \frac{u}{\|u\|} \;=\; s + \frac{\langle x - s \mid u \rangle}{\|u\|^2} u$$

□

Proof of (4.123):



In elementary geometry you have to be extra-careful to distinguish between formal arguments and intuitive insights (that may not convince someone who doesn't share the insight). As we aim to be as rigorous as possible the proof might require more effort than expected. We will rely on the sine rule

$$\frac{\sin(\alpha)}{a} \;=\; \frac{\sin(\beta)}{b} \;=\; \frac{\sin(\gamma)}{c}$$

and prove this along the way. If $x = 0$ or $y = 0$ then we have $0 = 0$ so there is nothing to prove. Otherwise we start with $A = 0$, $B = x \neq 0$ and $C = y \neq 0$ and define $S := \mathbb{R}y \subseteq \mathbb{R}^n$. Then S is a line in $\mathbb{R}^n$ and we may use (4.122.(iii)) to find the projection $p \in \mathbb{R}^n$ of x onto S. By said proposition this is given to be

$$p \;=\; \frac{\langle x, y \rangle}{\|y\|^2} y \quad\Longrightarrow\quad \|p\| = \frac{|\langle x, y \rangle|}{\|y\|^2}\, \|y\| = \frac{|\langle x, y \rangle|}{\|y\|}$$

However we will need to distinguish two cases: $\alpha \leq \pi/2$ first and $\alpha > \pi/2$ second. In the first case the triangle looks like

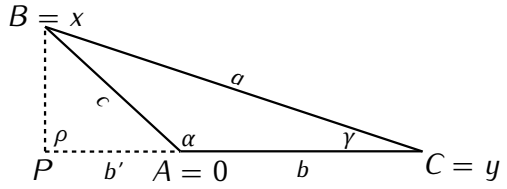
- Let us first prove the sine rule $c \cdot \sin(\alpha) = a \cdot \sin(\gamma)$: If we choose P such that the angle $\varrho = \pi/2$ is right, then we may use the definition of sine to already find

$$c \cdot \sin(\alpha) \;=\; d \;=\; a \cdot \sin(\gamma)$$

- Note that by construction $p \in \mathbb{R}^n$ is the one point $p \in S$ for which the distance d is minimal. Let us argue, that in this case $\varrho = \pi/2$ is a right angle: By the sine rule applied to ABp we have

$$d \cdot \sin(\varrho) \;=\; c \cdot \sin(\alpha) \quad\Longrightarrow\quad \sin(\varrho) \;=\; \frac{c \cdot \sin(\alpha)}{d}$$

 As $c \cdot \sin(\alpha)$ is fixed and d is as small as it can be, $\sin(\varrho)$ is as large, as it can be, which is $\sin(\varrho) = 1$. And this is the case for a right angle $\varrho = \pi/2$, which also yields $P = p$.



- Then we can use $\|p\|$ and the definition of cosine to compute the angle

$$\cos(\alpha) \;=\; \frac{b_1}{c} \;=\; \frac{\|p\|}{\|x\|} \;=\; \frac{|\langle x, y \rangle|}{\|x\| \cdot \|y\|}$$

As $\alpha \leq \pi/2$ we have it, that P lies in the positive direction of y, when looking from $A = 0$. That is $p = ay$ for some $a > 0$. And as $a = \langle x, y\rangle$ we have $|\langle x, y\rangle| = \langle x, y\rangle$ such that finally

$$\cos(\alpha) \;=\; \frac{\langle x, y\rangle}{\|x\| \cdot \|y\|}$$

So we now turn our attention to the case $\alpha \geq \pi/2$, in this second case the triangle looks a little different

- Again we start by proving the sine rule $c \cdot \sin(\alpha) = a \cdot \sin(\gamma)$ in that case, too: Choose P such that the angle $\varrho = \pi/2$ is right, then by the definition of sine again

 $$c \cdot \sin(\alpha') \;=\; d \;=\; a \cdot \sin(\gamma)$$

 But $\alpha' = \pi - \alpha$ and hence it is clear from the symmetry of the circle in the definition of sine, that $\sin(\alpha') = \sin(\pi - \alpha) = \sin(\alpha)$ such that the sine rule is complete.

- Applying the sine rule to ABp again, we find $P = p$, as before. The proof has been independent of the shape of the triangle.

- This time P lies in the negative direction of y, when looking from A. That is $P = ay$ for some $\langle x, y\rangle = a < 0$ such that $|\langle x, y\rangle| = -\langle x, y\rangle$. And cosine computes the complementary angle $\alpha' = \pi - \alpha$ only

 $$\cos(\alpha') \;=\; \frac{b'}{c} \;=\; \frac{\|p\|}{\|x\|} \;=\; \frac{|\langle x, y\rangle|}{\|x\| \cdot \|y\|}$$

 But from the symmetry of the circle in the definition of cosine it also is clear that $\cos(\alpha') = \cos(\pi - \alpha) = -\cos(\alpha)$ such that we arrive at the same formula, as the minus sign can be scratched

 $$-\cos(\alpha) \;=\; \cos(\alpha') \;=\; \frac{|\langle x, y\rangle|}{\|x\| \cdot \|y\|} \;=\; -\frac{\langle x, y\rangle}{\|x\| \cdot \|y\|}$$

□

Proof of (4.126):
First of all it is straightforward to see, that $\langle a, b\rangle = \langle a, a \wedge x\rangle = 0$ from the definition of the scalar and wedge product:

$$\begin{aligned}
\langle a, a \wedge x\rangle &= a_1(a_2x_3 - a_3x_2) + a_2(a_3x_1 - a_1x_3) + a_3(a_1x_2 - a_2x_1) \\
&= a_1a_2x_3 - a_1a_3x_2 + a_2a_3x_1 - a_1a_2x_3 + a_1a_3x_2 - a_2a_3x_1 \\
&= 0
\end{aligned}$$

Generally we have $a \wedge x = b$ if and only if $b_1 = a_2x_3 - a_3x_2$ and $b_2 = a_3x_1 - a_1x_3$ and $b_3 = a_1x_2 - a_2x_1$. Let us reformulate the third and second equations into $a_1x_2 = b_3 + a_2x_1$ and $a_1x_3 = -b_2 + a_3x_1$

respectively. Then we find, that

$$a_1 x \;=\; \begin{pmatrix} a_1 x_1 \\ a_1 x_2 \\ a_1 x_3 \end{pmatrix} \;=\; \begin{pmatrix} 0 \\ b_3 \\ -b_2 \end{pmatrix} + x_1 \begin{pmatrix} a_1 \\ a_2 \\ a_3 \end{pmatrix}$$

This already is the first equation $a_1 x = (0, b_3, -b_1) + x_1 a$ of the claim and in complete analogy we see the other two identities $a_2 x = (-b_3, 0, b_1) + x_2 a$ and $a_3 x = (b_2, -b_1, 0) + x_3 a$. If now $a_1 \in R^*$ is invertible, then we get

$$x \;=\; a_1^{-1} \begin{pmatrix} 0 \\ b_3 \\ -b_2 \end{pmatrix} + (a_1^{-1} x_1) \begin{pmatrix} a_1 \\ a_2 \\ a_3 \end{pmatrix} \;\in\; \begin{pmatrix} 0 \\ a_1^{-1} b_3 \\ -a_1^{-1} b_2 \end{pmatrix} + Ra$$

Thus we have proved the inclusion $L \subseteq (0, a_1^{-1} b_3, -a_1^{-1} b_1) + Ra$ for the set of solutions $L := \{\, x \in R^3 \mid a \wedge x = b \,\}$. Again, in complete analogy to this case we also find $L \subseteq (-a_2^{-1} b_3, 0, a_2^{-1} b_1) + Ra$ whenever $a_2 \in R^*$ and $L \subseteq (a_3^{-1} b_2, -a_3^{-1} b_1, 0) + Ra$ supposed $a_3 \in R^*$ respectively. It remains to prove the converse inclusions: So let us assume $\langle a, b \rangle = 0$ and $a_1 \in R^*$ and pick up any $u \in R$. Then for $x = (0, a_1^{-1} b_3, -a_1^{-1} b_1) + ua$ we need to show $a \wedge x = b$. First of all it is clear that $a \wedge (b + c) = a \wedge b + a \wedge c$ and $a \wedge a = 0$ such that

$$a \wedge x \;=\; a \wedge \begin{pmatrix} 0 \\ a_1^{-1} b_3 \\ -a_1^{-1} b_2 \end{pmatrix} + u(a \wedge a) \;=\; a \wedge \begin{pmatrix} 0 \\ a_1^{-1} b_3 \\ -a_1^{-1} b_2 \end{pmatrix}$$

And evaluating this expression by the definition of the wedge product finally yields $a \wedge x = b$, using $a_2 b_2 + a_3 b_3 = -a_1 b_1$ in the following computation

$$\begin{aligned} a \wedge x \;&=\; \begin{pmatrix} -a_2 a_1^{-1} b_2 - a_3 a_1^{-1} b_3 \\ a_3 \cdot 0 + a_1 a_1^{-1} b_2 \\ a_1 a_1^{-1} b_3 - a_2 \cdot 0 \end{pmatrix} \;=\; \begin{pmatrix} -a_1^{-1}(a_2 b_2 + a_3 b_3) \\ b_2 \\ b_3 \end{pmatrix} \\ &=\; \begin{pmatrix} -a_1^{-1}(-a_1 b_1) \\ b_2 \\ b_3 \end{pmatrix} \;=\; \begin{pmatrix} b_1 \\ b_2 \\ b_3 \end{pmatrix} \;=\; b \end{aligned}$$

In complete analogy we can prove $a \wedge x = b$ for the like cases, in which we have $\langle a, b \rangle = 0$ and $a_2 \in R^*$ or $a_3 \in R^*$ respectively. □

Proof of (4.128):
Properties (1) to (3) and (5) are immediate from the definition of the wedge product. Property (4) is immediate from (6) as $\langle x \wedge y, x \rangle = \det(x, y, x) = 0$ and $\langle x \wedge y, y \rangle = \det(x, y, y) = 0$. So we start with (6) which is a straightforward computation: Let $n := x \wedge y$ that is $n_1 = x_2 y_3 - x_3 y_2$, $n_2 = x_3 y_1 - x_1 y_3$ and $n_3 = x_1 y_2 - x_2 y_1$ then

$$\begin{aligned} \langle x \wedge y, z \rangle \;&=\; n_1 z_1 + n_2 z_2 + n_3 z_3 \\ &=\; x_2 y_3 z_1 - x_3 y_2 z_1 + x_3 y_1 z_2 \\ &\quad\; - x_1 y_3 z_2 + x_1 y_2 z_3 - x_2 y_1 z_3 \end{aligned}$$

$$
\begin{aligned}
&= x_1y_2z_3 + x_2y_3z_1 + x_3y_1z_2 \\
&\quad -x_2y_1z_3 - x_3y_2z_1 - x_1y_3z_2 \\
&= \det(x\ y\ z)
\end{aligned}
$$

We will show (7) by another direct computation, let $n := x \wedge y$ again, then

$$
\begin{aligned}
(x \wedge y) \wedge z &= \begin{pmatrix} n_2z_3 - n_3z_2 \\ n_3z_1 - n_1z_3 \\ n_1z_2 - n_2z_1 \end{pmatrix} \\
&= \begin{pmatrix} x_3y_1z_3 - x_1y_3z_3 - x_1y_2z_2 + x_2y_1z_2 \\ x_1y_2z_1 - x_2y_1z_1 - x_2y_3z_3 + x_3y_2z_3 \\ x_2y_3z_2 - x_3y_2z_2 - x_3y_1z_1 + x_1y_3z_1 \end{pmatrix} \\
\langle x,z\rangle y &= \begin{pmatrix} x_1z_1y_1 + x_2z_2y_1 + x_3z_3y_1 \\ x_1z_1y_2 + x_2z_2y_2 + x_3z_3y_2 \\ x_1z_1y_3 + x_2z_2y_3 + x_3z_3y_3 \end{pmatrix} \\
&= \begin{pmatrix} x_1y_1z_1 + x_2y_1z_2 + x_3y_1z_3 \\ x_1y_2z_1 + x_2y_2z_2 + x_3y_2z_3 \\ x_1y_3z_1 + x_2y_3z_2 + x_3y_3z_3 \end{pmatrix} \\
\langle y,z\rangle x &= \begin{pmatrix} y_1z_1x_1 + y_2z_2x_1 + y_3z_3x_1 \\ y_1z_1x_2 + y_2z_2x_2 + y_3z_3x_2 \\ y_1z_1x_3 + y_2z_2x_3 + y_3z_3x_3 \end{pmatrix} \\
&= \begin{pmatrix} x_1y_1z_1 + x_1y_2z_2 + y_1y_3z_3 \\ x_2y_1z_1 + x_2y_2z_2 + x_2y_3z_3 \\ x_3y_1z_1 + x_3y_2z_2 + x_3y_3z_3 \end{pmatrix}
\end{aligned}
$$

From these we find $(x \wedge y) \wedge z = \langle x,z\rangle y - \langle y,z\rangle x$ and thereby $x \wedge (y \wedge z) = -(y \wedge z) \wedge x = -\langle y,x\rangle z + \langle z,x\rangle y = \langle x,z\rangle y - \langle x,y\rangle z$. Now (8) is an immediate consequence of (7): Clearly the following terms sum up to zero:

$$
\begin{aligned}
x \wedge (y \wedge z) &= \langle x,z\rangle y - \langle x,y\rangle z \\
y \wedge (z \wedge x) &= \langle y,x\rangle z - \langle y,z\rangle y \\
z \wedge (x \wedge y) &= \langle z,y\rangle x - \langle z,x\rangle z
\end{aligned}
$$

For property (9) convince yourself that the k-th coefficient of $x \wedge y$ can be expressed in the following way: For $k \in 1\ldots3$ pick up $i, j \in 1\ldots3$ such that $i < j$ and $\{\, i,j,k \,\} = 1\ldots3$, then

$$
[x \wedge y]_k = (-1)^{k+1}(x_iy_j - x_jy_i)
$$

That is for $k = 1$ we have $(i,j) = (2,3)$, for $k = 2$ we have $(i,j) = (1,3)$ and for $k = 3$ we have $(i,j) = (1,2)$. Hence in the scalar product $\langle u \wedge v, x \wedge y\rangle$ the signs $(-1)^{k+1}$ cancel each other and the

sum $k = 1$ to 3 turns into the sum over $(i,j) \in (1\ldots3)^2$ with $i < j$

$$\begin{aligned}\langle u \wedge v, x \wedge y\rangle &= \sum_{k=1}^{3} [u \wedge v]_k \, [x \wedge y]_k \\ &= \sum_{i<j} (u_i v_j - u_j v_i)\,(x_i y_j - x_j y_i)\end{aligned}$$

So let us check what we find for $\langle u,x\rangle\langle v,y\rangle - \langle u,y\rangle\langle v,x\rangle$, if we evaluate this expression we see that for $i = j$ the terms in the difference cancel each other, such that we can split the sum into two parts again

$$\begin{aligned}&\langle u,x\rangle\langle v,y\rangle - \langle u,y\rangle\langle v,x\rangle \\ = \;& \left(\sum_{i=1}^{3} u_i x_i\right)\left(\sum_{j=1}^{3} v_j y_j\right) - \left(\sum_{i=1}^{3} u_i y_i\right)\left(\sum_{j=1}^{3} v_j x_j\right) \\ = \;& \sum_{i=1}^{3}\sum_{j=1}^{3} \left(u_i x_i v_j y_j - u_i y_i v_j x_j\right) \\ = \;& \sum_{i\neq j} u_i v_j \big(x_i y_j - y_i x_j\big) \\ = \;& \sum_{i<j} u_i v_j \big(x_i y_j - y_i x_j\big) + \sum_{i>j} u_i v_j \big(x_i y_j - y_i x_j\big)\end{aligned}$$

The bracket in the sum over $i > j$ is symmetric in i and j up to sign. Thus if we interchange i and j in this sum we pick up a minus:

$$\begin{aligned}&\langle u,x\rangle\langle v,y\rangle - \langle u,y\rangle\langle v,x\rangle \\ = \;& \sum_{i<j} u_i v_j \big(x_i y_j - y_i x_j\big) - \sum_{i<j} u_j v_i \big(x_i y_j - y_i x_j\big) \\ = \;& \sum_{i<j} \big(u_i v_j - u_j v_i\big)\big(x_i y_j - y_i x_j\big) \\ = \;& \langle u \wedge v, x \wedge y\rangle\end{aligned}$$

To prove property (10) we take a look at the matrix A having the columns x and y, that is $A = (x\,y) \in \mathrm{mat}_{3,2}(\mathbb{R})$. By definition of the column-rank we have c-rank$(A) = 2$ if and only if $\{\,x, y\,\}$ is linear independent. But as $\mathbb{R}$ is an integral domain (even a field) we have c-rank(A) = m-rank(A) due to (4.86) and the (2×2)-minors of A are given to be $m_1 = x_1y_2 - x_2y_1$, $m_2 = x_1y_3 - x_3y_1$ and $m_3 = x_2y_3 - x_3y_2$. That is the wedge product $x \wedge y = (m_3, m_2, m_1)$ contains precisely these minors. In particular we have m-rank$(A) = 2$ if and only if $x \wedge y \neq 0$.

For we next part we take a look at the cofactor matrix first. By it's definition for any $n \in R^3$ the i-th coefficient of $\mathrm{cof}(A)\,n$ is

$$[\mathrm{cof}(A)\,n]_i \;=\; \sum_{j=1}^{3} (-1)^{i+j} \det\big(A_{i,j}\big)\, n_j$$

Let $B := (0,x,y) \in \mathrm{mat}_3(R)$ be the matrix with the columns 0, x and y. Then $AB = (0, Ax, Ay)$ is the matrix with the columns 0, Ax and Ay. Also it is easy to see, that

$$\det\big(B_{1,1}\big) \;=\; x_2y_3 - x_3y_2 \;=\; [x \wedge y]_1$$

$$\begin{aligned}\det(B_{2,1}) &= x_1y_3 - x_3y_1 = -[x \wedge y]_2\\ \det(B_{3,1}) &= x_1y_2 - x_2y_1 = [x \wedge y]_3\end{aligned}$$

We will look at the components of $Ax \wedge Ay$ one by one: We may use property (5) to extract the first coefficient of $Ax \wedge Ay$ as a determinant

$$\begin{aligned}[Ax \wedge Ay]_1 &= \langle e_1, Ax \wedge Ay\rangle = \det(e_1, Ax, Ay)\\ &= 1 \cdot \det\begin{pmatrix}[Ax]_2 & [Ay]_2\\ [Ax]_3 & [Ay]_3\end{pmatrix} = \det\big((AB)_{1,1}\big)\end{aligned}$$

Let $n := x \wedge y$ again. We now apply the formula of Cauchy-Binet to AB, where we choose $\alpha = (2,3)$ and $\gamma = (2,3) \in \mathrm{Asc}(2,3)$. Then

$$\det\big((AB)_{1,1}\big) = \det\big(AB[\alpha \mid \gamma]\big) = \sum_{\beta \in \mathrm{Asc}(2,3)} \det\big(A[\alpha \mid \beta]\big)\det\big(B[\beta \mid \gamma]\big)$$

Note that the sum over $\beta \in \mathrm{Asc}(2,3)$ runs over $(1,2)$, $(1,3)$ and $(2,3)$ which are the complements of 3, 2 and 1 respectively, that is

$$\begin{aligned}[Ax \wedge Ay]_1 &= \det\big((AB)_{1,1}\big) = \sum_{j=1}^{3} \det\big(A_{1,j}\big)\det\big(B_{j,1}\big)\\ &= \det\big(A_{1,1}\big)\, n_1 - \det\big(A_{1,2}\big)\, n_2 + \det\big(A_{1,3}\big)\, n_3\\ &= [\mathrm{cof}(A)\, n]_1\end{aligned}$$

In the same way we are able to prove $[Ax \wedge Ay]_2 = -\det((AB)_{1,2})$ and by choosing $\alpha = (1,3)$ we get $\det((AB)_{1,2}) = -[\mathrm{cof}(A)\, n]_2$. And lastly (with $\alpha = (1,2)$) also $[Ax \wedge Ay]_3 = \det((AB)_{1,3})$ and $\det((AB)_{1,3}) = [\mathrm{cof}(A)\, n]_3$. As we have the equality for any component this finally is

$$Ax \wedge Ay = \mathrm{cof}(A)\, n = \mathrm{cof}(A)\, (x \wedge y)$$

Now we are up to the geometric properties of the wedge product: Let us denote the parallelogram spanned by x and y by $P := \mathrm{Ph}\{\, x, y\,\}$ and the parallelepiped spanned by x, y and z by $Q := \mathrm{Ph}\{\, x, y, z\,\}$. In order to prove $\|x \wedge y\| = \mathrm{Area}(P)$ we use property (9) of the wedge product with $u = x$ and $v = y$. If α is the angle between x and y then we use (4.123) to compute

$$\begin{aligned}\|x \wedge y\|^2 &= \langle x \wedge y, x \wedge y\rangle = \langle x, x\rangle \cdot \langle y, y\rangle - \langle x, y\rangle \cdot \langle y, x\rangle\\ &= \|x\|^2 \cdot \|y\|^2 - (\langle x, y\rangle)^2\\ &= \|x\|^2 \cdot \|y\|^2 - \|x\|^2 \cdot \|y\|^2 \cdot \cos(\alpha)^2\\ &= \|x\|^2 \cdot \|y\|^2 \cdot \big(1 - \cos(\alpha)^2\big)\\ &= \|x\|^2 \cdot \|y\|^2 \cdot \sin(\alpha)^2\end{aligned}$$

Note that for any $\alpha \in [0, \pi]$ the sine $\sin(\alpha) \geq 0$ is positive. Thus we may simply scratch the square from

this equation to find the formula of the area

$$\|x \wedge y\| \;=\; \|x\| \cdot \|y\| \cdot \sin(\alpha) \;=\; \text{Area}(P)$$

For the final formula of the volume, note that $x \wedge y$ is perpendicular to both x and y, according to property (4). That is $x \wedge y$ is perpendicular to the plane P lies in and thereby the angle between $x \wedge y$ and z is $\pi/2 - \beta$. Thus (4.123) again tells us

$$\begin{aligned}
\langle x \wedge y, z \rangle &= \|x \wedge y\| \cdot \|z\| \cdot \cos(\pi/2 - \beta) \\
&= \|x \wedge y\| \cdot \|z\| \cdot \sin(\beta) \\
&= \text{Area}(P) \cdot \|z\| \cdot \sin(\beta) \\
&= \text{Vol}(Q)
\end{aligned}$$

□

Proof of (4.130):
We find from the figure in (4.130), that the trapezoid $T = ABCD$ can be decomposed into two triangles ABD and BCD and hence its area is $\text{Area}(T) = \text{Area}(ABD) + \text{Area}(BCD)$. Let us denote $u := B - A$, $v := D - A$, $x := B - C$ and $y := D - C$. Then our assumption of a trapezoid amounts to $-y = C - D = t(B - A) = tu$ and therefore $x \wedge y = -tx \wedge u = tu \wedge x$. Also $u + x + y = B - A + C - B + D - C = D - A = v$ is clear and hence

$$\begin{aligned}
u \wedge v &= u \wedge (u + x + y) \;=\; u \wedge u + u \wedge x + u \wedge y \\
&= 0 + u \wedge x + 0 \;=\; u \wedge x
\end{aligned}$$

As $x \wedge y = tu \wedge x = tu \wedge v$ we find $\text{Area}(BCD) = (1/2) \;\| x \wedge y \| = (t/2) \;\| u \wedge v \|$ and therefore $\text{Area}(T) = \text{Area}(ABD) + \text{Area}(BCD) = (1 + t)/2 \;\|u \wedge v\|$. But we get the same result for

$$\begin{aligned}
\Big((B - A) + (C - D)\Big) \wedge (C - A) &= (u - y) \wedge (v - y) \\
&= u \wedge v - u \wedge y - y \wedge v + y \wedge y \\
&= u \wedge v + v \wedge y = u \wedge v + x \wedge y \\
&= (1 + t) u \wedge v
\end{aligned}$$

and hence the claim $\text{Area}(T) = (1 + t)/2 \;\|u \wedge v\| = (1/2) \;\|(u - y) \wedge (v - y)\|$. □

Proof of (4.131):
Let us denote $U := \text{Lh}\{\, u, v \,\}$ and $S := s + U$. Define $n := u \wedge v$ and $h := \langle n, s \rangle$ as in the theorem and denote $N := \big\{\, x \in \mathbb{R}^3 \mid \langle n, x \rangle = h \,\big\}$. Then we need to show $S = N$. The inclusion $S \subseteq N$ is easy: If $x \in S$, then x is of the form $x = s + au + bv$ for some a, $b \in \mathbb{R}$. But by (4.128.(3)) we have $\langle n, u \rangle = 0$ and $\langle n, v \rangle = 0$ such that

$$\langle n, x \rangle \;=\; \langle n, s + au + bv \rangle \;=\; \langle n, s \rangle + a \cdot \langle n, u \rangle + b \cdot \langle n, v \rangle \;=\; \langle n, s \rangle \;=\; h$$

which is $x \in N$ already. For the converse inclusion $N \subseteq S$ we look at the map $f : \mathbb{R}^3 \to \mathbb{R} : x \mapsto \langle n, x \rangle$. As $\{\, u, v \,\}$ is linear independent we have $n \neq 0$, due to property (10) of the wedge-product. Thus $f \neq 0$

and thereby $\dim(\mathrm{im}(f)) = 1$. The dimension formula (3.68.(iii)) then implies

$$\dim(\mathrm{kn}(f)) \;=\; \dim(\mathbb{R}^3) - \dim(\mathrm{im}(f)) \;=\; 3-1 \;=\; 2$$

So $P := \mathrm{kn}(f) = \{\, x \in \mathbb{R}^3 \mid \langle n, x\rangle = 0 \,\}$ is 2-dimensional. But as $f(u) = \langle n, u\rangle = 0$ and $f(v) = \langle n, v\rangle = 0$ we already have $U \subseteq P$. If there was some $p \in P \setminus U$, then $\{\, u, v, p \,\} \subseteq P$ were linearly independent which cannot be, as $\dim(P) = 2$. Thus we have $U = P$. We will finally show $N = s + P$. To see this consider any $x \in \mathbb{R}^3$, then $x \in N$ is equivalent, to $f(x) = \langle n, x\rangle = h = \langle n, s\rangle = f(s)$ which is equivalent to $f(x - s) = 0$ which is equivalent to $x - s \in P$ which finally is equivalent to $x \in s + P$. Thus we have $N = s + P$ and thereby $S = s + U = s + P = N$. □

Proof of (5.36):
If $a_j = \lambda$ then $\varphi(m_j) = a_j m_j$ turns into $\varphi(m_j) = \lambda m_j$ and hence $m_j \in \mathrm{Eig}_\varphi(\lambda)$. For the converse incluison we need to verify, that any $x \in \mathrm{Eig}_\varphi(\lambda)$ is a linear combination of those m_j such that $a_j = \lambda$. But as $\{\, m_1, \ldots, m_n \,\}$ is a basis we may write

$$x \;=\; \sum_{j=1}^{n} x_j m_j$$

for some $x_j \in R$. Now apply φ to x, on one side we have $\varphi(x) = \lambda x$, as $x \in \mathrm{Eig}_\varphi(\lambda)$. On the other side φ is R-linear and any $x_j m_j$ is mapped to $x_j a_j m_j$ by assumption on φ. That is we find the identity

$$\lambda x \;=\; \varphi(x) \quad\Longrightarrow\quad \sum_{j=1}^{n} \lambda x_j m_j \;=\; \sum_{j=1}^{n} x_j a_j m_j$$

Subtracting the sums, and using the fact, that the m_j are linearly independent, we get $(a_j - \lambda)x_j = 0$ for any $j \in 1 \ldots n$. As R is an integral domain we get $a_j = \lambda$ or $x_j = 0$ for any $j \in 1 \ldots n$. That is

$$x \;\in\; \mathrm{Lh}\{\, m_j \mid j \in 1 \ldots n,\, a_j = \lambda \,\}$$

as all the x_j with $a_j \neq \lambda$ have to be zero. As we started with an arbitrary $x \in \mathrm{Eig}_\varphi(\lambda)$ this also proves the converse inclusion and hence $\mathrm{Eig}_\varphi(\lambda)$ and $\mathrm{Lh}\{\, m_j \mid j \in 1 \ldots n,\, a_j = \lambda \,\}$ are identical. □

Proof of (5.37):

(i) Clearly the sum and intersection of the P_i are sub-modules of M, by (3.27.(ii)) and (3.10) respectively. It remains to prove the invariance under φ: (1) Consider any $x \in \sum_i P_i$ that is x is a finite sum of elements $x_i \in P_i$. Formally there is a finite subset $\Omega \subseteq I$ and $x_i \in P_i$ (where $i \in \Omega$) such that

$$x \;=\; \sum_{i\in\Omega} x_i \quad\Longrightarrow\quad \varphi(x) \;=\; \sum_{i\in\Omega} \varphi(x_i)$$

As $x_i \in P_i$ and P_i is φ-invariant, we have $\varphi(x_i) \in P_i$ again. And from this we see, that $\varphi(x)$ is contained in $\sum_i P_i$ again. (2) Consider any $x \in \bigcap_i P_i$ that is $x \in P_i$ for any $i \in I$. As P_i is φ-invariant we find $\varphi(x_i) \in P_i$ again (for any $i \in i$) and hence $\varphi(x) \in \bigcap_i P_i$ again.

(ii) Since R is commutative $x \mapsto \pi - \lambda\mathbb{1}$ is a linear map. And therefore $\mathrm{Eig}_\varphi(\lambda) \;\leq_{\mathtt{m}}\; M$ is a sub-module, since it is the kernel of this map $\varphi - \lambda\mathbb{1} \in \mathrm{end}(M)$. It remains to prove that $\mathrm{Eig}_\varphi(\lambda)$ also

is invariant under φ. To do this consider any $x \in \mathrm{Eig}_\varphi(\lambda)$, then we have $\varphi(x) = \lambda x \in \mathrm{Eig}_\varphi(\lambda)$ again, as $\mathrm{Eig}_\varphi(\lambda)$ is a sub-module.

Now, if M is torsion free, then we continue: By definition $ax \in \mathrm{Eig}_\varphi(\lambda)$ means $\varphi(ax) = \lambda ax$. On the other hand we have $\varphi(ax) = a\varphi(x)$ such that a $\varphi(x) = \lambda ax$. As R is commutative, this is $a(\varphi(x) - \lambda x) = 0$. Now, as M is torsion free, this implies $\varphi(x) = \lambda x$, which is $x \in \mathrm{Eig}_\varphi(\lambda)$ again.

(iii) Since M is free and finitely generated $d(\lambda) := \det(\varphi - \lambda \mathbb{1}_M)$ is well-defined. By definition of the spectrum $\lambda \in \mathrm{Spec}(\varphi)$ if and only if $\ker(\varphi - \lambda \mathbb{1}_M) \neq 0$. But since R is an integral domain (4.65.(ii)) tells us that this is the case if and only if $d(\lambda) = 0$.

(iv) We will prove the statement by induction on n: For $n = 1$ we consider some $a_1 x_1 = 0$. As $x_1 \neq 0$ by assumption and M is torsion-free we get $a_1 = 0$ and hence $\{ x_1 \}$ is linearly independent. For the induction step $n \to n+1$ we consider

$$\sum_{i=1}^{n+1} a_i x_i \;=\; 0 \quad\Longrightarrow\quad a_{n+1} x_{n+1} \;=\; -\sum_{i=1}^{n} a_i x_i$$

$$\begin{aligned}
\varphi(a_{n+1}x_{n+1}) &= a_{n+1}\varphi(x_{n+1}) \;=\; a_{n+1}\lambda_{n+1}x_{n+1} \\
&= \lambda_{n+1}a_{n+1}x_{n+1} \;=\; -\lambda_{n+1}\sum_{i=1}^{n} a_i x_i \\
&= -\sum_{i=1}^{n} a_i \lambda_{n+1} x_i \\
\varphi(a_{n+1}x_{n+1}) &= \varphi\left(-\sum_{i=1}^{n} a_i x_i\right) \;=\; -\sum_{i=1}^{n} a_i \varphi(x_i) \\
&= -\sum_{i=1}^{n} a_i \lambda_i x_i
\end{aligned}$$

Thus since we have found two separate expressions for $\varphi(a_{n+1}x_{n+1})$ these have to be equal. And thereby we arrive at a new equation

$$\Longrightarrow\quad -\sum_{i=1}^{n} a_i \lambda_{n+1} x_i \;=\; -\sum_{i=1}^{n} a_i \lambda_i x_i$$

$$\Longrightarrow\quad \sum_{i=1}^{n} a_i \left(\lambda_{n+1} - \lambda_i\right) x_i \;=\; 0$$

By induction hypothesis $\{ x_1, \ldots, x_n \}$ are linearly independent such that we conclude $a_i(\lambda_{n+1} - \lambda_i) = 0$ for any $i \in 1 \ldots n$. But since the λ_i are pairwise distinct we have $\lambda_{n+1} - \lambda_i \neq 0$ and as R is an integral domain this implies $a_i = 0$ for any $i \in 1 \ldots n$. But from this we also see $a_{n+1}x_{n+1} = 0$ and as $x_{n+1} \neq 0$ we conclude $a_{n+1} = 0$, as well. That is $x_1, \ldots, x_n, x_{n+1}$ is linearly independent.

(v) Consider any finite collection of elements $u_{i,j} \in U_i$ where $i \in 1 \ldots n$ and $j \in 1 \ldots m(i)$. If now $a_{i,j} \in R$ are any scalars, then we claimed

$$\sum_{i=1}^{n} \sum_{j=1}^{m(j)} a_{i,j}\, u_{i,j} \;=\; 0 \quad\Longrightarrow\quad \forall\, i \in 1 \ldots n, \forall\, j \in 1 \ldots m(i) \;:\; a_{i,j} \;=\; 0$$

To see this let $u_i := \sum_j a_{i,j}\, u_{i,j}$, as any $u_{i,j} \in U_i \subseteq \mathrm{Eig}_{\lambda_i}(\varphi)$ and the eigenspaces are sub-module of M by (ii) we find that $u_i \in \mathrm{Eig}_{\lambda_i}(\varphi)$. Suppose $u_i \neq 0$ for some $i \in 1 \dots n$, as $u_1 + \dots + u_n = 0$ by assumption this would imply $1 = 0$ due (iv). But as $R \neq 0$ this is not the case. Therefore we have $u_i = 0$ for all $i \in 1 \dots n$. Now

$$u_i \;=\; \sum_{j=1} a_{i,j}\, u_{i,j} \;=\; 0 \quad \Longrightarrow \quad \forall\, j \in 1 \dots m(i) \;:\; a_{i,j} \;=\; 0$$

since all the U_i were supposed to be linearly independent. That is we have $a_{i,j} = 0$ for any $j \in 1 \dots m(i)$ and this for any $i \in 1 \dots n$.

□

Proof of (5.43):
Items (i), (ii), (iv) and (v) are clear, we only have to prove the remaining statements (ii), (iii) and (vi): But (iii) is covered in (4.58.(iii)) and this also yields $c_A(t)$ in (ii), as for $A = \mathrm{dia}(a_1, \dots, n_n)$ we find

$$c_A(t) \;=\; \prod_{j=1}^{n}(t - a_j) \;=\; \prod_{i=1}^{r}(t - \lambda_i)^{k(i)}$$

For the minimal polynomial m_A we assume R to be a noetherian integral domain. Note that, as A is a diagonal matrix, for any $f \in R[t]$ we have $f(A) = \mathrm{dia}(f(a_1), \dots, f(a_n))$. In particular

$$m_A(A) \;=\; \mathrm{dia}\left(\prod_{i=1}^{r}(a_1 - \lambda_i), \dots, \prod_{i=1}^{r}(a_n - \lambda_i)\right) \;=\; \mathrm{dia}(0, \dots, 0) \;=\; 0$$

Also m_A is monic by construction, so it only remains to prove property (3), which is $f(A) = 0$ implies $m_A \mid f$. The assumption $0 = f(A) = \mathrm{dia}(f(a_1), \dots, f(a_n))$ means $f(a_j) = 0$ for any $j \in 1 \dots n$. As $f(t) = q(t) \cdot (t - a_j) + f(a_j)$ (by division with remainder) we hence find $t - a_j \mid f$. In particular $t - \lambda_i \mid f$ for any $i \in 1 \dots r$. But then the $t - \lambda_i$ are pairwise non-associate prime elements of $R[t]$, that all divide f. In other words $\langle t - \lambda_i \mid f \rangle \geq 1$. And thereby (2.59.(vi)) implies

$$m_A \;=\; \prod_{i=1}^{r}(t - \lambda_i) \;\mid\; \prod_{i=1}^{r}(t - \lambda_i)^{\langle t - \lambda_i | f \rangle} \;\mid\; f$$

The proof of (vi) splits into two parts: First we need to show that the characteristic polynomial $c_C(t)$ of the companion matrix $C := \mathrm{comp}(f)$ truly is f again. This is not hard, using induction on the degree n of f: For $n = 1$ we have $f = t + a_0$ and $C = (-a_0)$ a (1×1)-matrix. For this it is clear, that

$$\det(t\mathbb{1}_1 - C) \;=\; \det(t + a_0) \;=\; t + a_0 \;=\; f(t)$$

For the induction step, we have to regard the polynomial $f(t) = t^{n+1} + a_n t^n + \dots + a_1 t + a_0$. To evaluate

the charactristic polynomial of $C = \mathrm{comp}(f)$ we then use Laplace expansion along the first row

$$\det(t\mathbb{1}_{n+1} - C) \;=\; \det\begin{pmatrix} t & 0 & 0 & \cdots & 0 & a_0 \\ -1 & t & 0 & \cdots & 0 & a_1 \\ 0 & -1 & t & & 0 & a_2 \\ \vdots & & -1 & \ddots & & \vdots \\ \vdots & & & \ddots & t & a_{n-1} \\ 0 & 0 & 0 & & -1 & t + a_n \end{pmatrix} \;=\; t \cdot D_1 + (-1)^{n+1+1} a_0 \cdot D_{n+1}$$

Here we still have to take a closer look at the determinants D_1 and D_{n+1} of $n \times n$-matrices: Define the monic polynomial $f_1(t) := t^n + a_n t^{n-1} + \ldots a_2 t + a_1$ and let $C_1 := \mathrm{comp}(f_1)$, then we find

$$D_1 \;:=\; \det\begin{pmatrix} t & 0 & \cdots & 0 & a_1 \\ -1 & t & \cdots & 0 & a_2 \\ \vdots & -1 & \ddots & & \vdots \\ \vdots & & \ddots & t & a_{n-1} \\ 0 & 0 & & -1 & t + a_n \end{pmatrix} \;=\; \det(t\mathbb{1}_n - C_1)$$

$$D_{n+1} \;:=\; \begin{pmatrix} -1 & t & & 0 & 0 \\ 0 & -1 & \ddots & & 0 \\ \vdots & 0 & \ddots & \ddots & \vdots \\ \vdots & & & -1 & t \\ 0 & 0 & & 0 & -1 \end{pmatrix} \;=\; (-1)^n$$

Here $D_{n+1} = (-1)^n$ is obvious, as it is derived from an upper triangular matrix. And by induction hypothesis we have $D_1 = f_1(t)$ such that the above determinant of $t\mathbb{1}_{n+1} - C$ turns into

$$\det(t\mathbb{1}_{n+1} - C) \;=\; t \cdot f_1(t) + (-1)^{2n+2} a_0 \;=\; t \cdot f_1(t) + a_0 \;=\; f(t)$$

Thus we have completed the induction and found $c_C(t) = f(t)$. It remains to prove, that this also is the minimal polynomial $m_C(t) = f(t)$. However the proof of this needs some more advances in the theory - namely the Cayley-Hamilton theorem and (5.57). However we give the proof here, but abstain from using this property: First of all we have $f(C) = c_C(C) = 0$ by (5.44.(ii)). Let us now denote the endomorphism $\varphi : R^n \to R^n : x \mapsto Cx$. In the Euclidean basis $\mathcal{E}$ of R^n we then have $[\varphi]_\mathcal{E} = C = \mathrm{comp}(f)$. So by (5.57.(iii)) we find the following isomorphism of $R[t]$-modules

$$R[t] \Big/ fR[t] \;\xrightarrow{\sim}\; (R^n)_\varphi \;:\; g + fR[t] \;\mapsto\; ge_1$$

In particular: If $g \in R[t]$ is any polynomial satisfying $g(C) = 0$ then of course $0 = g(C)(e_1) = ge_1$. Due to the injectivety of the map this means $g + fR[t] = 0 + fR[t]$ and hence $f \mid g$. Therefore f satisfies the properties of the minimal polynomial and as this is unique, we have $f = m_C$. □

Proof of (5.44):

(i) Recall the explicit definition of the determinant of a square matrix A, as a sum over all permutations

of n and the respective products

$$\det(A) \;:=\; \sum_{\sigma\in S_n} \operatorname{sgn}(\sigma)\prod_{i=1}^{n} a_{i,\sigma(i)}$$

We will now cluster this sum: For any permutation $\sigma \in S_n$ let us denote the *fixed set* of σ by $\operatorname{fix}(\sigma) := \{\, i \in 1\ldots n \mid \sigma(i) = i \,\}$. Using this we can partition S_n into

$$S_n \;=\; \bigcup_{f=0}^{n} \bigcup_{\substack{F\subseteq 1\ldots n\\ \#F=f}} \{\, \sigma \in S_n \mid \operatorname{fix}(\sigma) = F \,\}$$

For any $i \in F = \operatorname{fix}(\sigma)$ we have $\sigma(i) = i$ by construction. Thus this partition enables us to rewrite the determinant into the form

$$\det(A) \;=\; \sum_{f=0}^{n}\sum_{\#F=f}\sum_{\operatorname{fix}(\sigma)=F} \operatorname{sgn}(\sigma)\prod_{i=1}^{n}\begin{cases} a_{i,i} \text{ if } i \in F \\ a_{i,\sigma(i)} \text{ if } i \notin F \end{cases}$$

If $i \notin F = \operatorname{fix}(\sigma)$ then $a_{i,\sigma(i)}$ is off the diagonal of A, so if we apply this to $\det(t\mathbb{1}_n - A)$ we find the following expression

$$c_A(t) \;=\; \sum_{f=0}^{n}\sum_{\#F=f}\sum_{\operatorname{fix}(\sigma)=F} \operatorname{sgn}(\sigma)\prod_{i=1}^{n}\begin{cases} t - a_{i,i} \text{ if } i \in F \\ -a_{i,\sigma(i)} \text{ if } i \notin F \end{cases}$$

We will prove that this expression can be reformulates as the equality

$$c_A(t) \;=\; \sum_{r=0}^{n}(-1)^{n-r}t^r \sum_{\alpha\in \operatorname{Asc}(n-r,n)} \det\big(A[\alpha \mid \alpha]\big)$$

As R is commutative, the product can be decomposed into two separate parts: Note that the product of the $(t - a_{i,i})$ can be rewritten as a polynomial in t. Thereby the coefficient of t^{f-k} is the elementary symmetric polynomial evaluated in the $a_{i,i}$ where $i \in F \subseteq 1\ldots n$. Let us denote $\operatorname{Asc}(k,F) := \{\, \gamma : 1\ldots k \to F \mid \gamma(1) < \gamma(2) < \cdots < \gamma(k) \,\}$ then these products can be rewritten as

$$\begin{aligned} \prod_{i\notin F}\big(-a_{i,\sigma(i)}\big) &= (-1)^{n-f}\prod_{i\notin F} a_{i,\sigma(i)} \\ \prod_{i\in F}(t - a_{i,i}) &= \sum_{k=0}^{f}(-1)^k t^{f-k} \sum_{\gamma\in\operatorname{Asc}(k,F)}\prod_{j=1}^{k} a_{\gamma(j),\gamma(j)} \end{aligned}$$

Since $\gamma(j) \in F$ for any $j \in 1\ldots k$ we have $\sigma(\gamma(j)) = \gamma(j)$. Thus if we denote $\overline{F} := (1\ldots n) \setminus F$ and $\overline{F} \cup \gamma := \overline{F} \cup \gamma(1\ldots k)$ then combining these two equations we find

$$\prod_{i=1}^{n}\begin{cases} t - a_{i,i} \text{ if } i \in F \\ -a_{i,\sigma(i)} \text{ if } i \notin F \end{cases}$$

$$= \sum_{k=0}^{f} (-1)^{n-f+k} t^{f-k} \sum_{\gamma \in \mathrm{Asc}(k,F)} \prod_{i \in \overline{F} \cup \gamma} a_{i,\sigma(i)}$$

Altogether we can rewrite the characteristic polynomial of A as $c_A(t) =$

$$\sum_{f=0}^{n} \sum_{\#F=f} \sum_{\mathrm{fix}(\sigma)=F} \mathrm{sgn}(\sigma) \sum_{k=0}^{f} (-1)^{n-f+k} t^{f-k} \sum_{\gamma \in \mathrm{Asc}(k,F)} \prod_{i \in \overline{F} \cup \gamma} a_{i,\sigma(i)}$$

We can pull the summation symbol $\sum_k$ in front, right behind $\sum_f$ by the associativity property of the addition, such that the summation runs over all indexes (f,k), where $f, k \in 0 \dots n$ and $k \leq f$. However we can rearrange this index set to the set (r,k), where $r, k \in 0 \dots n$ and $k \leq n-r$. The bijection of these is $(f,k) \mapsto (f-k,k)$ with inverse $(r,k) \mapsto (r+k,k)$. Therefore $c_A(t) =$

$$\sum_{r=0}^{n} (-1)^{n-r} t^r \sum_{k=0}^{n-r} \sum_{\#F=k+r} \sum_{\mathrm{fix}(\sigma)=F} \mathrm{sgn}(\sigma) \sum_{\gamma \in \mathrm{Asc}(k,F)} \prod_{i \in \overline{F} \cup \gamma} a_{i,\sigma(i)}$$

In case $r = n$ we have $k = 0$ and since $\#F = n$ necessarily $F = 1 \dots n$. Thus $\sigma = \mathbb{1}_n$ since this is the only permutation, that fixes the entire set $1 \dots n$. Therefore the case $i \notin F$ is void such that the coefficient of t^n equals 1. In any other case $r < n$ we have to show

$$\begin{aligned} & \sum_{k=0}^{n-r} \sum_{\#F=k+r} \sum_{\mathrm{fix}(\sigma)=F} \mathrm{sgn}(\sigma) \sum_{\gamma \in \mathrm{Asc}(k,F)} \prod_{i \in \overline{F} \cup \gamma} a_{i,\sigma(i)} \\ = & \sum_{\alpha \in \mathrm{Asc}(n-r,n)} \det\big(A[\alpha \mid \alpha]\big) \end{aligned}$$

But this is not too far away: Let us apply the above partition of S_{n-r} to the expression $\det(A[\alpha \mid \alpha])$, then we have the equality

$$\begin{aligned} & \sum_{\alpha \in \mathrm{Asc}(n-r,n)} \det\big(A[\alpha \mid \alpha]\big) \\ = & \sum_{\alpha \in \mathrm{Asc}(n-r,n)} \sum_{f=0}^{n-r} \sum_{\#F=f} \sum_{\mathrm{fix}(\varrho)=F} \mathrm{sgn}(\varrho) \prod_{i=1}^{n-r} \begin{cases} a_{\alpha(i),\alpha(i)} & \text{if } i \in F \\ a_{\alpha(i),\alpha\varrho(i)} & \text{if } i \notin F \end{cases} \end{aligned}$$

Rearranging a little we can pull out the summation symbol $\sum_f$ up front and push the summation $\sum_\alpha$ behind $\mathrm{sgn}(\varrho)$. Then we see that both expressions start with a summation from 0 to $n-r$. Thus if we take the same summation index $f = k$ it suffices to show the equality of

$$\begin{aligned} & \sum_{\#F=k+r} \sum_{\mathrm{fix}(\sigma)=F} \mathrm{sgn}(\sigma) \sum_{\gamma \in \mathrm{Asc}(k,F)} \prod_{i \in \overline{F} \cup \gamma} a_{i,\sigma(i)} \\ = & \sum_{\#F=f} \sum_{\mathrm{fix}(\varrho)=F} \mathrm{sgn}(\varrho) \sum_{\alpha \in \mathrm{Asc}(n-r,n)} \prod_{i=1}^{n-r} \begin{cases} a_{\alpha(i),\alpha(i)} & \text{if } i \in F \\ a_{\alpha(i),\alpha\varrho(i)} & \text{if } i \notin F \end{cases} \end{aligned}$$

Note that in these terms both products encompass $n-r$ entries of A. For $\det(A[\alpha \mid \alpha])$ this is obvious and for $c_A(t)$ note that $\#F = k+r$ such that $\#\overline{F} = n-k-k$ and as $\#\gamma(1 \dots k) = k$ and $\gamma(1 \dots k) \subseteq F$ this means $\#(\overline{F} \cap \gamma) = n-k+r+k = n-r$. Let us take a closer look at these

products

$$\prod_{i=1}^{n-r}\begin{cases} a_{\alpha(i),\alpha(i)} \text{ if } i \in F \\ a_{\alpha(i),\alpha\varrho(i)} \text{ if } i \notin F \end{cases} = \prod_{i\in F} a_{\alpha(i),\alpha(i)} \prod_{i\notin F} a_{\alpha(i),\alpha\varrho(i)}$$
$$\prod_{i\in\overline{F}\cup\gamma} a_{i,\sigma(i)} = \prod_{j\in\gamma(1\ldots k)} a_{j,j} \prod_{j\notin F} a_{j,\sigma(j)}$$

We are being a little sloppy, as in the upper term $F \subseteq I := 1\ldots(n-r)$ differs from $F \subseteq J := 1\ldots n$ in the lower term. Let us rename these sets F_I and F_J respectively. Then $\alpha : I \hookrightarrow J$ and $\varrho \in S_I$ such that we may consider $\sigma := \alpha\varrho\alpha^{-1}$. We can regard $\sigma \in S_I$ if we take $\sigma(j) := j$ for any $j \in 1\ldots n \setminus \alpha(I)$. With this continuation we find

$$\mathrm{fix}(\sigma) = \alpha(\mathrm{fix}(\varrho))\overline{\alpha(I)}$$

Prob If $j \notin \alpha(I)$ then $j \in \mathrm{fix}(\sigma)$ by construction and if $j = \alpha(i)$ then $j = \sigma(j) = \alpha\varrho\alpha^{-1}(j)$ if and only if $\alpha^{-1}(j) = \varrho\alpha^{-1}(j)$ which is $i = \varrho(i)$ or in other words $i \in \mathrm{fix}(\varrho)$ such that $j \in \alpha(\mathrm{fix}(\varrho))$.

Altogether, if we use the bijection $F_I \mapsto F_J := \alpha(F_I) \cup \overline{\alpha(I)}$ we turn the subset $F_I \subseteq 1\ldots(n-r)$ with f elements into a subset $F_J \subseteq 1\ldots n$ with $f+r$ elements. And if $F_I = \mathrm{fix}(\varrho)$ then for $\varrho \mapsto \sigma = \alpha\varrho\alpha^{-1}$ we find $\mathrm{fix}(\sigma) = F_J$. Thereby it is clear that $\mathrm{sgn}(\sigma) = \mathrm{sgn}(\varrho)$ as conjugation does not change the cyclic structure of ϱ. All we have to do is define $\gamma \in \mathrm{Asc}(k, F_J)$ to be the one ascending chain of indexes with $\gamma(1\ldots k) = \alpha(F_I)$. As F_I has $f = k$ elements and $\alpha(F_I) \subseteq F_J$, this is well defined. Thus we have translated the lower term into the upper term using $F_I \mapsto F_J$, $\varrho \mapsto \sigma$ and $\alpha \mapsto \gamma$. But from this construction it is clear that the products match each other

$$\prod_{j\in\gamma(1\ldots k)} a_{j,j} = \prod_{i\in F_I} a_{\alpha(i),\alpha(i)}$$
$$\prod_{j\notin F_J} a_{j,\sigma(j)} = \prod_{i\notin F_I} a_{\alpha(i),\alpha\varrho(i)}$$

(ii) Let $B := (t\mathbb{1}_n - A)^{\#} \in \mathrm{mat}_n(R[t])$ be the adjugate matrix of $t\mathbb{1}_n - A$, then (as $R[t]$ is a commutative ring) we have seen in (4.63.(iii)) that

$$(t\mathbb{1}_n - A)B = \det(t\mathbb{1}_n - A)\mathbb{1}_n = c_A(t)\mathbb{1}_n$$

That is we have n^2 equations in the polynomial ring $R[t]$ encoded in a single equation for $n \times n$ matrices over $R[t]$. And by construction the degree of all these polynomial equations is n. Let us now write

$$B = (t\mathbb{1}_n - A)^{\#} = \sum_{k=0}^{n-1} t^k B_k$$

for sufficient $B_k \in \mathrm{mat}_n(R)$, then the above equation takes the form

$$c_A(t)\mathbb{1}_n = (t\mathbb{1}_n - A)\sum_{k=0}^{n-1} t^k B_k = \sum_{k=0}^{n-1} t^{k+1} B_k - \sum_{k=0}^{n-1} t^k A B_k$$
$$= t^n B_{n-1} + \sum_{k=1}^{n-1} t^k (B_{k-1} - AB_k) - AB_0$$

Comparing coefficients yields $c_A[n]\mathbb{1}_n = B_{n-1}$ and hence $B_{n-1} = \mathbb{1}_n$ as $c_A(t)$ is monic: $c_A[n] = 1$. Also $AB_0 = -c_A[0]\mathbb{1}_n = -(-1)^n \det(A)\mathbb{1}_n$. Also this is no wonder, as $B_0 = -A^\#$. Also for any $k \in 1 \ldots (n-1)$

$$c_A[k]\mathbb{1}_k \;=\; B_{k-1} - AB_k$$

Let us now multiply all these equations with A^k from the left, that is $B_{n-1}A^n = A^n$ and for any $k \in 1 \ldots n-1$ we get

$$c_A[k]A^k \;=\; A^k B_{k-1} - A^{k+1}B_k$$

Then $c_A(A) = \sum_k c_A[k]A^k$ can be replaced in every coefficient $c_A[k]A^k$ separately to find a telescopic sum, that vanishes identically

$$\begin{aligned}
c_A(A) &= \sum_{k=0}^{n} c_A[k]A^k \;=\; A^n + \sum_{k=1}^{n-1} c_A[k]A^k + c_A[0]\mathbb{1}_n \\
&= A^n + \sum_{k=1}^{n-1} (A^k B_{k-1} - A^{k+1}B_k) + c_A[0]\mathbb{1}_n \\
&= A^n + \sum_{k=1}^{n-1} A^k B_{k-1} - \sum_{k=2}^{n} A^k B_{k-1} + c_A[0]\mathbb{1}_n \\
&= A^n + AB_0 - A^n B_{n-1} + c_A[0]\mathbb{1}_n \\
&= A^n - c_A[0]A - A^n + c_A[0]\mathbb{1}_n \;=\; 0
\end{aligned}$$

(iii) Pick up an ordered basis $\mathcal{M}$ of M and let $A := [\varphi]_{\mathcal{M}}$ be the matrix representation of $\varphi \in \mathrm{end}(M)$. Then the characteristic polynomial of φ has been defined, as $c_\varphi(t) = c_A(t) \in R[t]$. As $\varphi \mapsto [\varphi]_{\mathcal{M}}$ is an isomorphism of R-algebras, according to (4.40), we find

$$\big[c_\varphi(\varphi)\big]_{\mathcal{M}} \;=\; c_\varphi\left([\varphi]_{\mathcal{M}}\right) \;=\; c_\varphi(A) \;=\; c_A(A) \;=\; 0$$

as we have just seen in (ii). Therefore $c_\varphi(\varphi) = 0 \in \mathrm{end}(M)$ is the zero-map, which had to be proved.

(iv) As M is finitely generated we find some $x_k \in M$ such that $M = \mathrm{Lh}\{\, x_1, \ldots, x_n \,\}$ where $n = \mathrm{rank}(M)$. Now, as $\varphi(x_j) \in M$ again, for any $j \in 1 \ldots n$ we also find some $a_{i,j} \in R$ such that

$$\varphi(x_j) \;=\; \sum_{i=1}^{n} a_{i,j} x_i$$

Let $A := (a_{i,j}) \in \mathrm{mat}_n(R)$ be the $n \times n$ matrix of those coefficients. Then it is clear that for any $x = \sum_j b_j x_j \in M$ we get

$$\begin{aligned}
\varphi(x) &= \sum_{j=1}^{n} b_j \varphi(x_j) \;=\; \sum_{j=1}^{n} b_j \sum_{i=1}^{n} a_{i,j} x_i \\
&= \sum_{i=1}^{n} \left(\sum_{i=1}^{n} a_{i,j} b_j \right) x_i \;=\; \sum_{i=1}^{n} [Ab]_i \, x_i
\end{aligned}$$

where we denoted $b = (b_1, \ldots, b_n) \in R^n$ the coefficient-vector of x. And likewise $\varphi^k(x) =$

$\sum_i [A^k b]_i \, x_i$. Now let $f(t) := \det(t\mathbb{1}_n - A)$ be the characteristic polynomial of A again. Then we have shown in (i) that $f(A) = 0$. And hence for any $x = \sum_j b_j \in M$ we find

$$\begin{aligned} c(\varphi)(x) &= \sum_{k=0}^{n} f[k]\varphi^k(x) = \sum_{k=0}^{n} f[k] \sum_{i=1}^{n} [A^k b]_i \, x_i \\ &= \sum_{i=1}^{n} \left(\sum_{k=0}^{n} f[k][A^k b]_i \right) x_i = \sum_{i=1}^{n} \left[\sum_{k=0}^{n} f[k] A^k b \right]_i x_i \\ &= \sum_{i=1}^{n} [f(A)b]_i \, x_i = \sum_{i=1}^{n} 0 \, x_i = 0 \end{aligned}$$

(v) Let $\{ m_1, \ldots, m_n \}$ be a generating set of M as an R-module. Then by assumption $\varphi(m_i) \in \varphi(M) \subseteq \mathfrak{a}M$ and therefore by (3.40.(ii)) there are some elements $a_{i,j} \in \mathfrak{a}$ such that

$$\varphi(m_i) = \sum_{j=1}^{n} a_{i,j} m_j$$

Let $A := (a_{i,j}) \in \mathrm{mat}_n(R)$ be the $(n \times n)$-matrix of these coefficients $c_A \in R[t]$ be the characteristic polynomial of A. By (i) we have $c_A[0] = \pm\det(A)$ which is an n-fold product of the elements $a_{i,j}$. In particular $c_A[0] \in \mathfrak{a}$ [even $c_A[0] \in \mathfrak{a}^n$]. Likewise $c_A[n-1] = -\mathrm{tr}(A)$ and hence $c_A[n-1] \in \mathfrak{a}$ as well. Generally $c_A[k] \in \mathfrak{a}$ [even $c_A[k] \in \mathfrak{a}^{n-k}$] is clear, by the general formula in (i).

Let $R[\varphi] = \{ f(\varphi) \mid f \in R[t] \}$ be the sub-ring of $\mathrm{end}(M)$ generated by φ and note that this is a commutative ring. Then the above equations can be reformulated - for any $i \in 1 \ldots n$ - into

$$\sum_{j=1}^{n} (\delta_{i,j}\varphi - a_{i,j}\mathbb{1}) m_j = 0$$

Thus, if we regard the $(n \times n)$-matrix $\Phi := (\delta_{i,j}\varphi - a_{i,j}\mathbb{1}) \in \mathrm{mat}_n(R[\varphi])$ then we find that $\Phi(m_1, \ldots, m_n) = (0, \ldots, 0) \in M^n$. In particular by (4.63.(iii)) we have

$$\det(\Phi) \begin{pmatrix} m_1 \\ \vdots \\ m_n \end{pmatrix} = \Phi^{\#}\Phi \begin{pmatrix} m_1 \\ \vdots \\ m_n \end{pmatrix} = \Phi^{\#} \begin{pmatrix} 0 \\ \vdots \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ \vdots \\ 0 \end{pmatrix}$$

That is $\det(\Phi) \in R[\varphi]$ annihilates any $m_i \in M$ and therefore $\det(\Phi) = 0 \in \mathrm{end}(M)$. But oviously $\det(\Phi) = c_A(\varphi)$ and as we have argued above $c_A(t) \in R[t]$ is a polynomial of the required form.

□

Proof of (3.44):

(i) Let us denote $J := \{ i \in I \mid m_i \notin \mathfrak{a}M \}$, then we have to prove that $\{ m_j + \mathfrak{a}M \mid j \in J \}$ is an $(R/\mathfrak{a})$-basis of $M/\mathfrak{a}M$. So we first have to check, that this set $(R/\mathfrak{a})$-linearly generates $M/\mathfrak{a}M$. Thus consider any $x + \mathfrak{a}M \in M/\mathfrak{a}M$, that is $x \in M$. As the m_i generate M there are some $a_i \in R$ (where $i \in I$ and only finitely many $a_i \neq 0$ are non-zero), such that $x = \sum_i a_i m_i$. And thereby we

already get

$$\begin{aligned} x + \mathfrak{a}M &= \sum_{i\in I} a_i m_i + \mathfrak{a}M = \sum_{i\in I} (a_i + \mathfrak{a})(m_i + \mathfrak{a}M) \\ &= \sum_{i\in J} (a_i + \mathfrak{a})(m_i + \mathfrak{a}M) \end{aligned}$$

where the latter equality holds, as any $i \in I \setminus J$ yields $x_i + \mathfrak{a}M = 0 + \mathfrak{a}M$. It remains to prove the $(R/\mathfrak{a})$-linear independence of this set. Thus suppose we are given any $b_j + \mathfrak{a} \in R/\mathfrak{a}$ (of which only finitely many are non-zero) such that

$$0 + \mathfrak{a}M = \sum_{j\in J} (b_j + \mathfrak{a})(m_j + \mathfrak{a}M) = \sum_{j\in J} b_j m_j + \mathfrak{a}M$$

In other terms that is $\sum_j b_j m_j \in \mathfrak{a}M$. But as $\{ m_i \mid i \in I \}$ generates M we may use (3.40.(ii)) to find some $a_i \in \mathfrak{a}$, of which only finitely many are non-zero, such that

$$\sum_{j\in J} b_j m_j = \sum_{i\in I} a_i m_i$$

As the m_i form an R-basis of M we may compare coefficients in these two representations, which yields $a_i = 0$ for any $i \in I \setminus J$ and $b_j = a_j \in \mathfrak{a}$ for any $j \in J$. Hence we have $b_j + \mathfrak{a} = 0$ for any $j \in J$ and this is the $(R/\mathfrak{a})$-linear independence of $\{ m_j + \mathfrak{a}M \mid j \in J \}$.

(i) It remains to prove that the $m_i + \mathfrak{a}M$ are pairwise distinct, too. First, if $\mathfrak{a} = R$, then $\mathfrak{a}M = M$ and hence $m_i \in \mathfrak{a}M$ for any $i \in I$. In this case the basis given is empty and there is nothing to prove. So let us now assume $\mathfrak{a} \neq 0$. If $m_i + \mathfrak{a}M = m_j + \mathfrak{a}M$ then we have $m_i - m_j \in \mathfrak{a}M$. Yet as $\{ m_i \mid i \in I \}$ generates M we may use (3.40.(ii)) again, to find some $a_k \in \mathfrak{a}$, of which only finitely many are non-zero, such that

$$m_i - m_j = \sum_{k\in I} a_k m_k$$

If we had $i \neq j$ then this would yield an equation of R-linear dependence, simply by moving $m_i - m_j$ on the left hand side and decomposing

$$(a_i - 1)m_i + (a_j + 1)m_j + \sum_{\substack{k\in I,\\ k\neq i,j}} a_k m_k = 0$$

As the m_i are R-linearly independent this implies all coefficients in this equation to be 0, in particular $1 = a_i \in \mathfrak{a}$. That is $\mathfrak{a} = R$ which cannot occur. Hence we necesserily have $i = j$.

(ii) (a) $\implies$ (b): let us choose a generating set $\{ m_1, \ldots, m_n \}$ of M with a minimal number n of elements. Suppose $n \geq 1$ then, as $m_1 \in M = \mathfrak{a}M$ we may invoke (3.40.(ii)) to find some $a_1, \ldots, a_n \in \mathfrak{a}$ such that $m_1 = a_1 m_1 + \cdots + a_n m_n$. Let us now write this equation in the form

$$(1 - a_1)m_1 = a_2 m_2 + \cdots + a_n m_n$$

As $a_1 \in \mathfrak{a} \in \operatorname{JAC}(R)$ we know by (2.8) that $1 - a_1 \in R^*$ is invertible. And hence m_1 is contained in

the linear hull of $\{ m_2, \ldots, m_n \}$ by

$$m_1 \;=\; \sum_{i=2}^{n} (1-a_1)^{-1} a_i \, m_i$$

That is even $\{ m_2, \ldots, m_n \}$ generates M in contradiction to the minimality of the number n of generators. So our assumption $n \geq 1$ has been false, that is $n = 0$ and hence $M = 0$.

$\neg$ (a) $\Longrightarrow$ $\neg$ (b): if $\mathfrak{a} \not\subseteq \operatorname{JAC}(R)$ then - by definition of the Jacobson radical - there is a maximal ideal $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} R$ of R such that $\mathfrak{a} \not\subseteq \mathfrak{m}$. And this again means that there is some $u \in \mathfrak{a}$ with $u \notin \mathfrak{m}$. Now, as $M := R/\mathfrak{m}$ is a field, and $u + \mathfrak{m} \neq 0 \in M$ there is some $v + \mathfrak{m} \in M$ such that $uv + \mathfrak{m} = (u + \mathfrak{m})(v + \mathfrak{m}) = 1 + \mathfrak{m}$. Clearly M also is finitely generated, by $\{ 1 + \mathfrak{m} \}$ as an R-module. Also

$$\begin{aligned} \mathfrak{a}M &= \{ ab + \mathfrak{m} \mid a \in \mathfrak{a},\ b \in R \} \\ &= \{ c + \mathfrak{m} \mid c \in R \} \;=\; M \end{aligned}$$

Hereby the central equality is due to the following reasoning: given $c \in R$ we may take $a := u$ and $b := vc$, that $ab + \mathfrak{m} = uvc + \mathfrak{m} = c + \mathfrak{m}$, and the converse inclusion is clear. Thus we have found a finitely generated R-module M with $\mathfrak{a}M = M$, but $M \neq 0$.

(ii) **Alternative Version:** the more advanced lemma of Dedekind allows to prove the implication (a) $\Longrightarrow$ (b) in a straightforward way: as M is finitely generated we find some $a \in \mathfrak{a}$ such that $(1-a)M = 0$, due to (v). Yet as $a \in \mathfrak{a} \subseteq \operatorname{JAC}(R)$ proposition (2.8) yields that $1 - a \in R^*$ is invertible. Hence $M = (1-a)M = 0$ is proved already.

(iii) By (3.40.(v)) we have know that $\mathfrak{a}(M/P)$ equals $(\mathfrak{a}M + P)/P$ and hence we have the following identities (by the assumptions on P)

$$\mathfrak{a}\left(M \Big/ P \right) \;=\; \mathfrak{a}M + P \Big/ P \;=\; M \Big/ P$$

Yet M/P is finitely generated and $\mathfrak{a} \subseteq \operatorname{JAC}(R)$ so by the lemma of Nakayama (ii) we get $M/P = 0$ and this is nothing but $M = P$.

(iv) If φ is surjective, then $\varphi/\mathfrak{a}$ clearly is surjective as well - see (3.40.(vi)) for details. So conversely assume $\varphi/\mathfrak{a}$ is surjective, that is for any $y \in N$ there is some $x \in M$ that

$$y + \mathfrak{a}N \;=\; \varphi \Big/ \mathfrak{a}(x + \mathfrak{a}M) \;=\; \varphi(x) + \mathfrak{a}N$$

That is $v := y - \varphi(x) \in \mathfrak{a}N$, such that $y = \varphi(x) + v$. As y has been arbitrary this means $N = \operatorname{im}(\varphi) + \mathfrak{a}N$. Yet as $N/\operatorname{im}(\varphi)$ is finitely generated and $\mathfrak{a} \subseteq \operatorname{JAC}(R)$ this implies $\operatorname{im}(\varphi) = N$ by (iii), which is nothing, but the surjectivity of φ.

(v) ($\diamondsuit$) If φ is bijective, then $\varphi/\mathfrak{m}$ is bijective for any ideal $\mathfrak{a} \subseteq R$, as we have seen in (3.40.(vii)). Conversely: as M is finitely generated, the zero-module $0 \leq_{\mathfrak{m}} M$ is cofinite and hence also $\operatorname{im}(\varphi) \leq_{\mathfrak{m}} M$ is cofinite. So by (iv) we already know, that φ is surjective, as $\varphi/\mathfrak{a}$ is surjective (even bijective). But a surjective endomorphism of a finitely generated R-module already is bijective by (5.44).

(vi) ($\diamondsuit$) Consider the identity-map $\mathbb{1} : M \to M : x \mapsto x$ on M. Clearly this is an R-linear map satisfying $\mathrm{im}(\mathbb{1}) \subseteq M = \mathfrak{a}M$. And as M is finitely generated the Cayley-Hamilton theorem (5.44) yields some polynomial $f = t^n + a_1 t^{n-1} + \cdots + a_n \in R[t]$ such that $f(\mathbb{1}) = 0$ and $a_k \in \mathfrak{a}^k$ for any $k \in 1 \ldots n$. Now compute

$$\begin{aligned} f(\mathbb{1}) &= \mathbb{1}^n + a_1\mathbb{1}^{n-1} + \cdots + a_{n-1}\mathbb{1} + a_n\mathbb{1} \\ &= (1 + a_1 + \cdots + a_n)\mathbb{1} \;=\; (1-a)\mathbb{1} \end{aligned}$$

where we let $a := -(a_1 \cdots + a_n) \in \mathfrak{a}$. Now $0 = \mathrm{im}(0) = \mathrm{im}(f(\mathbb{1})) = \mathrm{im}((1-a)\mathbb{1}) = (1-a)M$. That is the $a \in \mathfrak{a}$ we constructed using Cayley-Hamilton truly satisfies $(1-a)M = 0$.

□

Proof of (3.82):

(iii) In case of a skew-field S things are simple now: according to the dimension formula (3.68.(iii)) we know that

$$\dim(V) \;=\; \dim(\mathrm{kn}(\varphi)) + \dim(\mathrm{im}(\varphi))$$

This if φ is injective then we have $\mathrm{kn}(\varphi) = 0$ and hence $\dim(\mathrm{kn}(\varphi)) = 0$ which leaves $\dim(V) = \dim(\mathrm{im}(\varphi))$. Thus (as V is finite dimensional) by (3.64.(ix)) we find that $\mathrm{im}(\varphi) = V$ such that φ is surjective.

Conversely if φ is surjective, then $\mathrm{im}(\varphi) = V$ and hence $\dim(\mathrm{im}(\varphi)) = \dim(V)$, which leaves $\dim(\mathrm{kn}(\varphi) = 0$. Therefore $\mathrm{kn}(\varphi) = 0$ [if there was some $0 \neq x \in \mathrm{kn}(\varphi)$, then $\{ x \}$ would be a linearly independent set in $\mathrm{kn}(\varphi)$ and hence $\dim(\mathrm{kn}(\pi)) \geq 1$]. But of course this means that φ is injective.

So in any case we have seen surjective implies bijective and injective implies bijective. And the converse implications are trivial.

(ii) Any power of φ is an endomorphism again, so let us consider the following descending chain of sumbodules of M

$$\mathrm{im}(\varphi) \;\supseteq\; \mathrm{im}(\varphi^2) \;\supseteq\; \ldots \;\supseteq\; \mathrm{im}(\varphi^n) \;\supseteq\; \mathrm{im}(\varphi^{n+1}) \;\supseteq\; \ldots$$

As M is artinian this chain has to stabilize, that is there is some $n \in \mathbb{N}$ such that $\mathrm{im}(\varphi^n) = \mathrm{im}(\varphi^{n+1}) = \ldots$. Let us denote $\psi := \varphi^n$. Then $\psi : M \to M$ still is injective and if we denote $P := \mathrm{im}(\psi)$, then trivially $\psi : M \to P$ is surjective and hence an isomorphism of modules. Yet we also get

$$P \;=\; \mathrm{im}(\psi) \;=\; \mathrm{im}(\varphi^n) \;=\; \mathrm{im}(\varphi^{2n}) \;=\; \mathrm{im}(\psi^2) \;=\; \psi^2(M) \;=\; \psi(P)$$

From $\psi(P) = P$ we also find, that $\psi : P \xrightarrow{\sim} P$ is an automorphism on P. Now consider any $x \in M$ and let $y := \psi(x) \in P$. As $\psi : P \xrightarrow{\sim} P$ we find that $x = \psi^{-1}(y) \in P$. Hence $M \subseteq P \subseteq M$ such that $\psi : M \xrightarrow{\sim} M$ is an automorphism on M. Thus φ must have been bijective already, the inverse is given to be $\varphi^{n-1}\psi^{-1}$.

(i) **Dedekind-Proof**: We will first present a rather short proof using the lemma of Dedekind: Let us regard M as an $R[t]$-module by virtue of (5.53). Then by construction we get $tx = \varphi(x)$ for any

$x \in M$ hence, as φ is surjective, for any $y \in M$ there is some $x \in M$ with $tx = y$. Hence we get $tM = M$, in particular $\mathfrak{a}M = M$ for $\mathfrak{a} := tR[t] \trianglelefteq_{\mathfrak{i}} R[t]$. Now by then lemma of Dedekind (3.44.(vi)) there is some $g \in \mathfrak{a}$ such that $(1-g)M = 0$. As $g \in \mathfrak{a}$ there is some $f \in R[t]$ with $g(t) = tf(t)$. Let us define $\psi := g(\varphi) \in \mathrm{end}(M)$. Then $gx = g(\varphi)(x) = \psi(x)$ for any $x \in M$ and hence $(1-f)M = 0$ implies

$$0 \;=\; (1 - tg(t))x \;=\; x - t\psi(x) \;=\; x - \varphi(\psi(x))$$

$$0 \;=\; (1 - gt(t))x \;=\; x - g\varphi(x) \;=\; x - \psi(\varphi(x))$$

That is $\varphi(\psi(x)) = x$ and $\psi(\varphi(x)) = x$ for any $x \in M$. That is ψ is just the inverse map of φ and in particular φ is bijective.

(i) **Noether-Proof**: As the proof above requires the somewhat abstract Dedekind lemma, we would like to supply another proof that requires the theory of noetherian modules only. As M is finitely generated there are some $x_i \in M$ such that $M = \mathrm{Lh}(x_1, \ldots, x_n)$. Then, as $\varphi(x_j) \in M$ we can pick up some $p_{i,j} \in R$ such that

$$\varphi(x_j) \;=\; \sum_{i=1}^{n} p_{i,j} x_i$$

Step (A): we will now prove, that $M = \mathrm{Lh}(\varphi(x_1), \ldots, \varphi(x_n))$. That is we choose some $y \in M$ arbitarily. As φ is surjective there is some $x \in M$ such that $y = \varphi(x)$. And hence there are some $a_j \in R$ such that $x = \sum_j a_j x_j$. Now compute

$$y \;=\; \varphi(x) \;=\; \sum_{j=1}^{n} a_j \varphi(x_j) \;\in\; \mathrm{Lh}\Big(\varphi(x_1), \ldots, \varphi(x_n)\Big)$$

Step (B): as the $\varphi(x_j)$ generate M we can conversely choose some $q_{j,i} \in R$ such that the $x_i \in M$ can be written as

$$x_i \;=\; \sum_{j=1}^{n} q_{j,i} \varphi(x_j)$$

Remember all we have to prove is the injectivity of φ. And to do this it suffices to prove $\mathrm{kn}(\varphi) = 0$. Hence regard some $k \in M$ with $\varphi(k) = 0$. All we have to prove is $k = 0$, then the injectivity is established.

Step (C): write k as $k = \sum_i k_i x_i$ for some $k_i \in R$ and let A denote the $\mathbb{Z}$-algebra generated by all the $p_{i,j}$ $q_{i,j}$ and k_i

$$A \;:=\; \mathbb{Z}\left[\bigcup_{i=1}^{n}\bigcup_{j=1}^{n} \{\, p_{i,j}, q_{i,j}, k_i \,\}\right]$$

Then A is finitely generated and $\mathbb{Z}$ is notherian (even a PID) such that A is a noetherian sub-ring of R, by the Hilbert basis theorem (2.42). Also let N be the A-sub-module of M that is generated by the x_i. As N is a finitely generated module over the noetherian ring N is a noetherian A-module itself

$$N \;:=\; \mathrm{Lh}_A(x_1, \ldots, x_n)$$

Step (D): we will now prove that $\varphi : N \to M$ restricts to $\varphi : N \to N$. That is we will prove that

$\varphi(x) \in N$ for any $x \in N$. But this is easy to see: if $x \in N$ then $x = \sum_j a_j x_j$ for some $a_j \in N$. Hence

$$\varphi(x) \;=\; \sum_{j=1}^{n} a_j \varphi(x_j) \;=\; \sum_{j=1}^{n} a_j \sum_{i=1}^{n} p_{i,j} x_i \;=\; \sum_{i=1}^{n} \sum_{j=1}^{n} p_{i,j} a_j x_i$$

and this is contained in N again, as $p_{i,j} \in A$ as well. Also we will prove that $\varphi : N \twoheadrightarrow N$ is surjective, that is for any $y \in N$ there is some $x \in N$ such that $y = \varphi(x)$. If $y = \sum_i b_i x_i$ then let $x := \sum_i b_i \sum_j q_{i,j} \in A$

$$\varphi(x) \;=\; \sum_{i=1}^{n} b_i \sum_{j=1}^{n} q_{i,j} \varphi(x_j) \;=\; \sum_{i=1}^{n} b_i x_i \;=\; y$$

Step (E): as $\varphi : N \to N$ is surjective, so is $\varphi^k : N \to N$. Now let $K_i := \mathsf{kn}(\varphi^k) \;\leq_{\mathsf{m}}\; N$. Then it is clear, that the K_i form an ascending chain of sub-modules of N

$$K_0 \;\subseteq\; K_1 \;\subseteq\; K_2 \;\subseteq\; \ldots$$

But as N is noetherian this chain has to stabilize, that is there is some $s \in \mathbb{N}$ such that $K_{s+1} = K_s$. As φ^s is surjective and $k \in N$, there is some $z \in N$ such that $k = \varphi^s(z)$. But now $0 = \varphi(k) = \varphi(\varphi^s(z)) = \varphi^{s+1}(z)$ implies $z \in K_{s+1} = K_s$. That is $k = \varphi^s(z) = 0$ already. Hence we have finally arrived at $k = 0$ which is the injectivity of $\varphi : M \to M$.

□

Proof of (5.53):
It is clear that $(M_\varphi, +)$ is a commutative group, as we did neither change the base set $M_\varphi = M$ nor the addition $+$ on M. It remains to prove the properties (M) of an $R[t]$-module. Thus consider any f, $g \in R[t]$ and any x, $y \in M$. As φ is R-linear so are the compositions φ^k and hence we can compute

$$\begin{aligned}
1x &= t^0 x \;=\; \varphi^0(x) \;=\; \mathbb{1}_M(x) \;=\; x \\
f(x+y) &= \sum_{k=0}^{\infty} f[k]\varphi^k(x+y) \;=\; \sum_{k=0}^{\infty} f[k]\left(\varphi^k(x) + \varphi^k(y)\right) \\
&= \sum_{k=0}^{\infty} f[k]\varphi^k(x) + \sum_{k=0}^{\infty} f[k]\varphi^k(y) \;=\; fx + fy \\
(f+g)x &= \sum_{k=0}^{\infty} (f[k] + g[k])\varphi^k(x) \\
&= \sum_{k=0}^{\infty} f[k]\varphi^k(x) + \sum_{k=0}^{\infty} g[k]\varphi^k(x) \;=\; fx + gx \\
f(gx) &= \sum_{i=0}^{\infty} f[i]\varphi^i\left(\sum_{j=0}^{\infty} g[j]\varphi^j(x)\right) \\
&= \sum_{i=0}^{\infty} f[i] \sum_{j=0}^{\infty} g[j]\varphi^i\left(\varphi^j(x)\right) \\
&= \sum_{i=0}^{\infty} \sum_{j=0}^{\infty} f[i]g[j]\varphi^{i+j}(x) \\
&= \sum_{k=0}^{\infty} \left(\sum_{i+j=k} f[i]g[j]\right)\varphi^k(x) \;=\; (fg)x
\end{aligned}$$

□

Proof of (5.55):

(i) First of all the additive structures of M and M_μ are just the same, so whether P is a sub-module $P \leq_{\mathsf{m}} M$ resp. $P \leq_{\mathsf{m}} M_\mu$ depends on whether it is closed under scalar multiplications only. Yet, if $a \in R$ and $x \in M$ then we have

$$(at^0)x \;=\; a\mathbb{1}_M(x) \;=\; ax$$

regardless of μ. So if P is a sub-module of M_μ then it already is a sub-module of M. Also note, that for any $x \in P$ we then get

$$\mu(x) \;=\; tx \;\in\; P$$

such that $\mu(P) \subseteq P$ for any $P \leq_{\mathsf{m}} M_\mu$. And if conversely $P \leq_{\mathsf{m}} M$ with $\mu(P) \subseteq P$, then by induction it is clear, that $\mu^k(P) \subseteq P$ for any $k \in \mathbb{N}$. But then we find $fx \in P$ for any $f \in R[t]$ and $x \in P$, since

$$\left(\sum_{k=0}^{n} a_k t^k\right) x \;=\; \sum_{k=0}^{n} a_k \mu^k(x) \;\in\; P$$

That is such a P is closed under scalar multiplications of $R[t]$ (and closed under addition from the start) such that $P \leq_{\mathsf{m}} M_\mu$.

(ii) As the additive structures of M and M_μ resp. of N and N_ν are just the same the $R[t]$-linearity of $\varphi : M_\mu \to N_\nu$ only depends on whether it respects the scalar multiplication. As $(at^0)x = ax$ again, we see that any $R[t]$-linear map $\varphi : M_\mu \to N_\nu$ already is R-linear, as well, since $\varphi(ax) = \varphi((at^0)x) = (at^0)\varphi(x) = a\varphi(x)$. Also note

$$\varphi\big(\mu(x)\big) \;=\; \varphi(tx) \;=\; t\varphi(x) \;=\; \nu\big(\varphi(x)\big)$$

So the $R[t]$-linearity also implies the commutativity $\varphi\mu = \nu\varphi$. Conversely if $\varphi : M \to N$ is R-linear and commutes with μ and ν then by induction it is clear that $\varphi\mu^k = \nu^k\varphi$ for any $k \in \mathbb{N}$ [with $k = 0$ being the R-liearity itself]. And this yields the $R[t]$-linearity of φ

$$\begin{aligned}\varphi\left(\left(\sum_{k=0}^{n} a_k t^k\right) x\right) \;&=\; \varphi\left(\sum_{k=0}^{n} a_k \mu^k(x)\right) \;=\; \sum_{k=0}^{n} a_k \varphi\left(\mu^k(x)\right)\\ &=\; \sum_{k=0}^{n} a_k \nu^k\left(\varphi(x)\right) \;=\; \left(\sum_{k=0}^{n} a_k t^k\right)\varphi(x)\end{aligned}$$

(iii) If $\Phi : M_\mu \xrightarrow{\sim} M_\varepsilon$ is an isomorphism, then by (ii) we already know that $\Phi : M \to M$ is a homomorphism with $\Phi\mu = \varepsilon\Phi$. But as Φ is bijective $\Phi : M \to M$ is an automorphism and we find $\Phi\mu\Phi^{-1} = \varepsilon$ by applying Φ^{-1} from the right. Conversely if $\Phi : M \xrightarrow{\sim} M$ is an automorphism with $\varepsilon = \Phi\mu\Phi^{-1}$ then equivalently $\Phi\mu = \varepsilon\Phi$ such that by (ii) again $\Phi : M_\mu \to M_\varepsilon$ is a homomorphism. But as Φ is bijective, this even is an isomorphism of these modules.

□

Proof of (5.56):

(i) Consider any fx, $gx \in R[t]$, then $fx + gx = (f+g)x$ and as $f+g \in R[t]$ this means $fx+gx \in R[t]$. Also for any $a \in R[t]$ we have $a(fx) = (af)x$ again, by (5.53). And as $af \in R[t]$ this means, that we also have $a(fx) \in R[t]$. In particular, for any $a \in R$, $ax = (a\mathbf{1})x \in R[t]$ such that $Rx \subseteq R[t]x$. It remains to prove, that $R[t]x$ is φ-invariant. Yet by definition of the scalar multiplication on M_φ we have $\varphi(fx) = t(fx) = (tf)x \in R[t]x$ again.

(i) Let us now prove the explicit description of $R[t]x$: Clearly $\varphi^k(x) = t^k x \in R[t]x$, such that the linear hull of the $\varphi^k(x)$ is contained in $R[t]x$. Conversely consider any $fx \in R[t]x$, that is $f \in R[t]$. Let $n := \deg(f)$, then we find that fx is contained in the linear hull, since

$$fx \;=\; \left(\sum_{k=0}^{n} f[k]t^k\right) x \;=\; \sum_{k=0}^{n} f[k]\varphi^k(x)$$

(ii) By (i) we only have to prove $R[t]x \subseteq \mathrm{Lh}_R\{\, \varphi^k(x) \mid 0 \leq k < n \,\}$, hence consider any $gx \in R[t]x$, as f is monic we may use division with remainder to find q, $r \in R[t]$ such that $g = qf + r$ and $\deg(r) < n$ (where $r = 0$ is allowed). But as $fx = 0$ this also yields

$$gx \;=\; (qf+r)x \;=\; q(fx)+rx \;=\; rx$$

As $\deg(r) < n$ this implies that gx is contained in the linear hull of the $\varphi^k(x)$ where $0 \leq k < n$ as, analogous to the above, we may compute

$$gx \;=\; rx \;=\; \left(\sum_{k=0}^{n-1} r[k]t^k\right) x \;=\; \sum_{k=0}^{n-1} r[k]\varphi^k(x)$$

(iii) As $x \in P$ and P is φ-invariant, we have $\varphi(x) \in P$ again. By induction on $k \in \mathbb{N}$ it is clear, that $\varphi^k(x) \in P$ - for $k = 0$ we observe $\varphi^0(x) = \mathbb{1}(x) = x \in P$ by assumption. And as P is a sub-module, this implies that the linear hull of all the $\varphi^k(x)$ is contained in P. But by (i) this already is $R[t]x \subseteq P$.

In particular, if P is generated by $\{\, p_i \mid i \in I \,\}$, then we have $Rp_i \subseteq R[t]p_i \subseteq P$ and hence $P = \sum_i Rp_i \subseteq \sum_i R[t]p_i \subseteq P$ such that we have the equality of P and the sum over all $R[t]p_i$.

(iv) Choose any generating set $\{\, m_i \mid i \in I \,\}$ of M as an R-module. Then by (iii) $\{\, m_i \mid i \in I \,\}$ also is a generating set of M_φ as an $R[t]$-module. In particular we (generally) have

$$\mathrm{rank}_{R[t]}(M_\varphi) \;\leq\; \mathrm{rank}_R(M)$$

Now assume that M is finitely generated, then as we have just argued M_φ is finitely generated, as well. Then by (5.44.(iv)) there is a polynomial $f \in R[t]$ of $\deg(f) = \mathrm{rank}(M)$ such that $f(\varphi) = 0$. That is $fx = 0$ for any $x \in M$ and thereby $f \in \mathrm{ann}(M_\varphi)$. In particular $\mathrm{tor}(M_\varphi) = M_\varphi$, which means that M_φ is a torsion-module.

□

Proof of (8.39):
Fix any ordered basis of S as an R-module and let $A := [\lambda_x]$ resp. $B := [\lambda_y]$ be the basis representations

of λ_x and λ_y in this basis respectively. Then it is clear, that $\lambda_{ax}(s) = (ax)s = a(xs) = a\lambda_x(s)$ and from this we get $\lambda_{ax} = a\lambda_x$. In particular $[\lambda_{ax}] = [a\lambda_x] = a[\lambda_x]$ such that λ_{ax} has the matrix representation aA. Therefore $T_{S:R}(ax) = \mathrm{tr}(aA) = a\mathrm{tr}(A) = aT_{S:R}(x)$ and $N_{S:R}(ax) = \det(aA) = a^n\det(A) = a^n N_{S:R}(x)$, the latter as det is a multi-linear form.
In complete analogy we have $\lambda_{x+y}(s) = (x+y)s = xs + ys = \lambda_x(s) + \lambda_y(s)$ such that $\lambda_{x+y} = \lambda_x + \lambda_y$ and hence $[\lambda_{x+y}] = [\lambda_x + \lambda_y] = [\lambda_x] + [\lambda_y]$ which means, that λ_{x+y} has the matrix representation $A + B$. Therefore $T_{S:R}(x+y) = \mathrm{tr}(A+B) = \mathrm{tr}(A) + \mathrm{tr}(B) = T_{S:R}(x) + T_{S:R}(y)$. Also $\lambda_x(\lambda_y(s)) = x(ys) = (xy)s = \lambda_{xy}(s)$ such that $\lambda_x\lambda_y = \lambda_{xy}$. That is $[\lambda_{xy}] = [\lambda_x\lambda_y] = [\lambda_x][\lambda_y]$ and thereby we have found the matrix representation of λ_{xy} to be AB. Now by (4.55.(ii)) this implies

$$N_{S:R}(xy) \;=\; \det\big(\lambda_{xy}\big) \;=\; \det\big(AB\big) \;=\; \det(A)\det(B) \;=\; N_{S:R}(x)\,N_{S:R}(y)$$

By definition we have $c_x(t) = c_{\lambda_x}(t)$ and hence $c_x(\lambda_x) = 0 \in \mathrm{end}(S)$ by the Cayley-Hamilton theorem (5.44.(iii)). Yet for any $f \in R[t]$ we have $f(\lambda_x) = \lambda_{f(x)}$ and hence in particular $0 = c_x(\lambda_x) = \lambda_{c_x(x)}$ such that $c_x(x) = c_x(x)1_S = \lambda_{c_x(x)}(1_S) = 0(1_S) = 0_S$. That is $c_x(x) = 0$, as claimed. And by (5.44.(i)) we also find $T_{S:R}(x)$ and $N_{S:R}(x)$ as coefficients of $c_x(t)$, as claimed in the proposition. □

Proof of (5.42):

(i) Let $S := R[\varphi] = \mathrm{Lh}\{\,\varphi^k \mid k \in \mathbb{N}\,\} \subset \mathrm{end}(M)$ be the sub-module of $\mathrm{end}(M)$ generated by the powers of φ. Then clearly S is closed under multiplication of elements (i.e. composition of maps) and hence a ring - even a commutative ring. Let $\iota : R \hookrightarrow S$ be the canonical embedding $\iota(a) = a\mathbb{1}_M$ and $\sigma : \mathbb{N} \to S : k \mapsto \varphi^k$. Then ι is a monomorphism of rings and σ is a homomorphism of monoids. Hence by (7.14) $\sigma_\iota : f \mapsto f(\varphi)$ is a well-defined homomorphism of rings. And it is clear that $\mathrm{kn}(\sigma_\iota) = \{\,f \in R[t] \mid f(\varphi) = 0\,\} \trianglelefteq_{\mathrm{i}} R[t]$ is the null ideal of φ.

(iii) If m satisfies (a), then (1) and (2) of (b) are given already. So consider any $f \in R[t]$ such that $f \neq 0$ and $f(\varphi) = 0$. By assumption (a) we hence find some $g \in R[t]$ such that $f = gm$. In particular $g \neq 0$, as $f \neq 0$, which id $\deg(g) \geq 0$. But then $\deg(f) = \deg(gm) = \deg(g) + \deg(m)$, as R is an integral domain, and hence $\deg(f) \geq \deg(m)$.

If m satisfies (b) then (1) of (c) is given already and we need to show that m generates the null ideal of φ. As $m(\varphi) = 0$ we have $mR[t] \subseteq \{\,f \in R[t] \mid f(\varphi) = 0\,\}$. Conversely consider any $f \in R[t]$ with $f(\varphi) = 0$. As m is monic we may use division with remainder (2.67) to find some g, $r \in R[t]$ such that $f = gm + r$ and $r = 0$ or $\deg(r) < \deg(m)$. In particular

$$0 \;=\; f(\varphi) \;=\; g(\varphi)m(\varphi) + r(\varphi) \;=\; g(\varphi)\cdot 0 + r(\varphi) \;=\; r(\varphi)$$

That is $r(\varphi) = 0$ again. Suppose we had $r \neq 0$, then this would imply $\deg(m) \leq \deg(r) < \deg(m)$ by assumption (b), which is a contradiciton. Hence we have $r = 0$ and this is $f = gm \in mR[t]$.

In m satisfies (c) then (1) of (a) is given already. Also $m(\varphi) = 0$ is trivial, as $m \in mR[t] = \{\,f \in R[t] \mid f(\varphi) = 0\,\}$. So it remains to prove (3): Given $f \in R[t]$ with $f(\varphi) = 0$ we have $f \in mR[t]$ and hence $f = gm$ for some $g \in R[t]$, which already is $m \mid f$.

(ii) Suppose the null ideal $\mathfrak{z} := \{\,f \in R[t] \mid f(\varphi) = 0\,\}$ of φ is principal, that is there is some $g \in R[t]$ such that $gR[t] = \mathfrak{z}$. By the Cayley-Hamilton theorem (5.44.(iii)) we have $c_\varphi(\varphi) = 0$ and hence

$c_\varphi \in \mathfrak{z} = gR[t]$. That is there is some $f \in R[t]$ such that $c_\varphi = fg$. Yet the characteristic polynomial c_φ is monic and hence $1 = \ln(c_\varphi) = \mathrm{lc}(f) \cdot \mathrm{lc}(g)$, as R is an integral domain. That is the leading coefficient $a := \mathrm{lc}(g)$ is a unit of R and hence $m := a^{-1}g$ is a monic polynomial that generates the $\mathfrak{z}$. In particular m satisfies property (c) of (iii) and thereby $m = m_\varphi$.

(iv) Consider f, $g \in \mathfrak{v}_\varphi$, that is $0 = (fg)(\varphi) = f(\varphi)g(\varphi)$. As R is an integral domain, this means $f(\varphi) = 0$ or $g(\varphi) = 0$ such that $f \in \mathfrak{v}_\varphi$ or $g \in \mathfrak{v}_\varphi$. That makes $\mathfrak{v}_\varphi$ a prime ideal of $R[t]$. Now let m be the minimal polynomial of φ an let $m \mid fg$. By property (c) of m in (iii) this means $fg \in \mathfrak{v}_\varphi$ and as we have just seen, this implies f or $g \in \mathfrak{v}_\varphi$. By (c) again, this is nothing but $m \mid f$ or $m \mid g$, which makes m a prime element of $R[t]$.

(v) Consider any $p \in P \subseteq M$ then $m_\varphi(\varphi)(p) = 0(p) = 0$ and as this is true for any $p \in P$ we have $m_\varphi(\varphi \mid P) = 0$. By definition of a minimal polynomial of $\varphi \mid P$, this already means $m_{\varphi|P} \mid m_\varphi$.

□

Proof of (5.46):

(i) First of all $\varphi^k(x) = \lambda^k x$ is clear by induction on k: For $k = 0$ we have $\varphi^0(x) = \mathbb{1}_M(x) = x = \lambda^0 x$. Now for the induction step $\varphi^{k+1}(x) = \varphi(\varphi^k(x)) = \varphi(\lambda^k x) = \lambda^k \varphi(x) = \lambda^k \lambda x = \lambda^{k+1} x$. Using this we are able to simply compute

$$\begin{aligned} f(\varphi)(x) &= \left(\sum_{k=0}^{\infty} f[k]\varphi^k\right)(x) = \sum_{k=0}^{\infty} f[k]\big(\varphi^k(x)\big) \\ &= \sum_{k=0}^{\infty} f[k]\big(\lambda^k x\big) = \left(\sum_{k=0}^{\infty} f[k]\lambda^k\right) x = f(\lambda)\, x \end{aligned}$$

(ii) As E is a field V is free (it has a basis), according to (3.65). Also, as E is a field, the polynomial ring $E[t]$ is an Euclidean domain by (2.71.(iii)) and hence a PID, by (2.79.(iii)). Now regard

$$\mathfrak{z} := \mathrm{kn}\big(f \mapsto f(\varphi)\big) = \{\, f \in E[t] \mid f(\varphi) = 0 \,\}$$

which is an ideal in $E[t]$. By the Cayley-Hamilton theorem (5.44.(iii)) we have $c_\varphi(\varphi) = 0$, such that $\mathfrak{z} \neq 0$ is non-zero. As $E[t]$ is a PID, we can choose a generator $g \in E[t]$ of $\mathfrak{z}$. Let $a \in E$ be the leading coefficient of g, then $m := a^{-1}g \in E[t]$ is a monic generator $mF[t] = \mathfrak{z}$, too and hence we have gained the minimal polynomial $m_\varphi = m$ of φ.

(iii) *Proof without the Lemma of Gauss in case of an UFD*: Let R be an UFD and $E := \mathrm{QUOT}(R)$ be the quotient field of R. We consider $R \hookrightarrow E$ as a sub-ring of E, via $a \mapsto a/1$. Also let $c_\varphi \in R[t]$ be the characteristic polynomial of φ. By (ii) there also is a minimal polynomial $m_\varphi \in E[t]$ that is a monic generator of the ideal

$$m_\varphi E[t] = \{\, f \in E[t] \mid f(\varphi) = 0 \,\}$$

As $c_\varphi(\varphi) = 0$ by (5.44.(iii)) there is some $r_\varphi \in E[t]$ such that $c_\varphi = r_\varphi m_\varphi$. And as $c_\varphi \in R[t]$ is monic (7.29.(ix)) tells us that there are some α, $\beta \in E$ and monic polynomials $\widetilde{m}_\varphi$ and $\widetilde{r}_\varphi$ such that $m_\varphi = \alpha \widetilde{m}_\varphi$ and $r_\varphi = \beta \widetilde{m}_\varphi$ and

$$c_\varphi = \widetilde{r}_\varphi \widetilde{m}_\varphi$$

As both m_φ and $\widetilde{m}_\varphi$ are monic and $m_\varphi = \alpha\widetilde{m}_\varphi$ we find $\alpha = 1$ and hence $m_\varphi = \widetilde{m}_\varphi$. In particular $m_\varphi \in R[t]$. We will now prove that m_φ also is the minimal polynomial of φ over R: That is we consider some $f \in R[t]$, such that $f(\varphi) = 0$ and have to prove $m_\varphi \mid f$ in $R[t]$. As m_φ generates $\{ f \in E[t] \mid f(\varphi) = 0 \}$, there is some $g \in E[t]$ such that $f = g\, m_\varphi$. Yet m_φ is monic, in particular primitive. But in this situation we already get $g \in R[t]$, by (7.29.(x)) and hence $m_\varphi \mid f$ in $R[t]$.

(iii) *Proof of the general claim in case of a normal domain*: Suppose R is a normal domain and let $E := \text{QUOT}(E)$ be the quotient field of R. As before, (ii) tells us that there is a minimal polynomial m_φ of φ over E. That is m_φ is the monic generator of the ideal

$$m_\varphi E[t] \;=\; \{ f \in E[t] \mid f(\varphi) = 0 \}$$

By Cayley-Hamilton (5.44.(iii)) we also find a monic polynomial $c_\varphi \in R[t]$ such that $c_\varphi(\varphi) = 0$. In particular m_φ divides c_φ in $E[t]$. That is there is some $q \in E[t]$ such that

$$c_\varphi \;=\; q m_\varphi \;\in\; R[t]$$

As both m_φ and c_φ are monic q has to be monic, too. That is we have m_φ and $q \in E[t]$ monic polynomials, such that $qm_\varphi \in R[t]$. As R is a normal domain, this implies q, $m_\varphi \in R[t]$, according to the lemma of Gauss (8.34).

Now that we have established $m_\varphi \in R[t]$ let us check that it also is a minimal polynomial in $R[t]$. That is given any $f \in R[t]$ such that $f(\varphi) = 0$ we have to find some $g \in R[t]$ such that $f = gm_\varphi$. To do this we use division with remainder (2.67), as m_φ is monic, to write f as

$$f \;=\; g\, m_\varphi + r$$

for some g, $r \in R[t]$ with $r = 0$ or $\deg(r) < \deg(m_\varphi)$. From this we get $0 = f(\varphi) = g(\varphi)m_\varphi(\varphi) + r(\varphi) = g(\varphi) \cdot 0 + r(\varphi) = r(\varphi)$, as $m_\varphi(\varphi) = 0$. But as m_φ is the minimal polynomial in $E[t]$ this implies $m_\varphi \mid r$ in $E[t]$. That is $r = p\, m_\varphi$ for some $p \in E[t]$. Suppose we had $r \neq 0$, then $p \neq 0$ and hence $\deg(r) = \deg(p) + \deg(m_\varphi) \geq \deg(m_\varphi)$. But this contradicts $\deg(r) < \deg(m_\varphi)$, which only leaves $r = 0$. That is $f = g\, m_\varphi$ for some $g \in R[t]$, which had to be shown.

(iv) The equivalence (a) $\iff$ (d) has been proven in (5.37.(iii)). For the equivalence of (d) and (b) choose any ordered basis $\mathcal{M}$ of M and let $A := [\varphi]_{\mathcal{M}}$. Then the characteristic polynomial of φ has been defined to be the characteristic polynomial of A: $c_\varphi(t) = c_A(t) = \det(t\mathbb{1}_n - A)$. That is for any $\lambda \in R$ we have

$$c_\varphi(\lambda) \;=\; \det(\lambda\mathbb{1}_n - A)$$

Yet the determinant of $\varphi - \lambda\mathbb{1}_M$ has also been defined by choosing a basis representation and one of these is given to be $[\varphi - \lambda\mathbb{1}_M]_{\mathcal{M}} = A - \lambda\mathbb{1}_n$. Hence

$$\det(\varphi - \lambda\mathbb{1}_M) \;=\; \det(A - \lambda\mathbb{1}_n) \;=\; (-1)^n c_\varphi(\lambda)$$

and in particular, both expressions share the same roots. That is (b) is equivalent to (d), too. We now prove (c) $\implies$ (b): By the Cayley-Hamilton theorem (5.44.(iii)) we have $c_\varphi(\varphi) = 0$. By the definition of the minimal polynomial, this means $m_\varphi \mid c_\varphi$, that is $c_\varphi(t) = q(t) \cdot m_\varphi(t)$ for some

$q \in R[t]$. If now $\lambda \in R$ satisfies $m_\varphi(\lambda) = 0$, then we also get

$$c_\varphi(\lambda) \;=\; q(\lambda) \cdot m_\varphi(\lambda) \;=\; 0$$

Conversely, for (b) $\implies$ (c) we are given some $\lambda \in R$ such that $c_\varphi(\lambda) = 0$. As (b) is equivalent to (a) we can choose some $x \in M$, such that $x \neq 0$ and $\varphi(x) = \lambda x$. Then by (i) we compute

$$m_\varphi(\lambda)x \;=\; m_\varphi(\varphi)(x) \;=\; 0(x) \;=\; 0$$

where we used $m_\varphi(\varphi) = 0$, which is property (1) of the minimal polynomial. But as R is an integral domain and M is free, M also is torsion-free, due to (3.23.(ii)). Hence $m_\varphi(\lambda)x = 0$ implies $m_\varphi(\lambda) = 0$, as $x \neq 0$. And this is (c).

(v) Let $P := \mathrm{Eig}_\varphi(\lambda) \;\leq_{\mathsf{m}}\; M$, then by (5.37.(ii)) P is a φ-invariant, pure sub-module of M. As we noted there, since R is a PID, we get from (4.109.(ii)) that P is complemented, that is

$$M \;=\; P \oplus Q$$

for some sub-module $Q \;\leq_{\mathsf{m}}\; M$. Note that M is free and R is a PID, such that any sub-module $P \;\leq_{\mathsf{m}}\; M$ is free, too - according to (3.104) Likewise $Q \xrightarrow{\sim} M/P : q \mapsto q + P$ is an isomorphism and $Q \;\leq_{\mathsf{m}}\; M$ is free, such that M/P is free, too. Pick up an orered basis $\mathcal{P} = (p_1, \ldots, p_r)$ of P and an ordered basis $\mathcal{Q} = (q_1, \ldots, q_s)$ of Q. As $M = P \oplus Q$ we hence get an ordered basis $\mathcal{M} := (p_1, \ldots, p_r, q_1, \ldots, q_s)$ of M. As any $p_i \in P = \mathrm{Eig}_\varphi(\lambda)$ we have $\varphi(p_i) = \lambda p_i$ and hence the matrix representation of φ in this basis is a block-matrix of the form

$$A \;:=\; [\varphi]_{\mathcal{M}} \;=\; \begin{pmatrix} \lambda \mathbb{1}_r & B \\ 0 & D \end{pmatrix}$$

If we evaluate the characteristic polynomial of A the determinant of $t\mathbb{1}_n - A$ is the product of the determinant of $t\mathbb{1}_r - \lambda\mathbb{1}_r$ and of $t\mathbb{1}_s - D$. And thereby we find

$$(t-\lambda)^r \;=\; \det(t\mathbb{1}_r - \lambda\mathbb{1}_r) \;\mid\; \det(t\mathbb{1}_r - \lambda\mathbb{1}_r) \cdot \det(t\mathbb{1}_s - D) \;=\; \det(t\mathbb{1}_r - A) \;=\; c_A(t)$$

This means $r \leq \mathrm{AM}_\varphi(\lambda)$, the multiplicity can be even higher, as $t - \lambda$ may also divide $\det(t\mathbb{1}_s - D)$. As λ *is* an eigenvalue there is at least one eigenvector and hence $r \geq 1$. Also $r = \dim(P) = \mathrm{GM}_\varphi(\lambda)$, by construction, such that $1 \leq r = \mathrm{GM}_\varphi(\lambda) \leq \mathrm{AM}_\varphi(\lambda)$.

□

Proof of (5.57):

(i) (a) $\implies$ (b): By assumption $M_\varphi = R[t]\,x$ for any $y \in M$ there is some $g \in R[t]$ such that $y = gx$. That is

$$y \;=\; g(\varphi)(x) \;=\; \sum_{k=0}^{\infty} g[k]\varphi^k(x)$$

In particular the set $\{\, \varphi^k(x) \mid k \in \mathbb{N} \,\}$ generates M as an R-module. (b) $\implies$ (c): It suffices to show that any $\varphi^m(x)$ can be written as an R-linear combination over the set $\{\, \varphi^k(x) \mid 0 \leq k < n \,\}$. As

c_φ is monic we may use division with remainder (2.67) to find (not necessarily unique) polynomials q and $r \in R[t]$ such that $t^m = qc_\varphi + r$ and also $\deg(r) < \deg(c_\varphi) = n$. By the theorem of Cayley-Hamilton (5.44.(iii)) we have $\varphi^m = t^m(\varphi) = q(\varphi)c_\varphi(\varphi) + r(\varphi) = r(\varphi)$ and hence $\varphi^m(x) = r(\varphi)(x)$. But as $\deg(r) < n$ we see that $r(\varphi)(x)$ and hence $\varphi^m(x)$ is contained in $\mathrm{Lh}_R\{\, \varphi^k(x) \mid 0 \le k < n \,\}$. (c) $\implies$ (d): By assumption M is a free module of dimension n. As $\{\, \varphi^k(x) \mid 0 \le k < n \,\}$ also contains n elements and generates M we find that this even is a basis of M according to (3.99.(ii))

(ii) Let us denote $x_k := \varphi^{k-1}(x)$ for any $k \in 1 \ldots n$. Since $x \in M$ is a cyclic vector property (d) tells us, that $(x_1, x_2, \ldots, x_n)$ is an ordered basis of M. And we clearly have $\varphi(x_k) = \varphi(\varphi^{k-1}(x)) = \varphi^k(x) = x_{k+1}$ for any $1 \le k < n$. Also there are coefficients $a_k \in R$ where $0 \le k < n$ such that $\varphi(x_n)$ can be expressed as a linear combination

$$\varphi(x_n) \;=\; \sum_{k=1}^{n} a_k\, x_k$$

Note that $\varphi(x_n) = \varphi\varphi^{n-1}(x) = \varphi^n(x) = t^n x$ and let us define the polynomial $f \in R[t]$ of degree n by $f(t) = t^n - a_n t^{n-1} - \cdots - a_2 t - a_1$. That is f has the the coefficients $f[n] = 1$ and $f[k] = -a_{k+1}$ for $0 \le k < n$. In particular we get $fx = \varphi^n(x) - \sum_k a_k \varphi^{k-1}(x) = 0$. If now $C := \mathrm{comp}(f)$ then for $1 \le k < n$ it is clear that $Ce_k = e_{k+1}$. This matches the property $\varphi(x_k) = x_{k+1}$. We also have

$$Ce_n \;=\; \sum_{k=1}^{n}(-f[k-1])e_k \;=\; \sum_{k=1}^{n} a_k e_k$$

So $Ce_n \in R^n$ is precisely the basis representation of $\varphi(x_n)$. Altogether C is the matrix representation of φ in terms of $\mathcal{M}$.

(iii) Let us abbreviate the companion matrix of f by $C := \mathrm{comp}(f)$. In particular we have $\deg(f) = n$ as the size of C equals $\#\mathcal{M} = n$. Then by definition of the companion matrix we find

$$[\varphi(x_k)]_{\mathcal{M}} \;=\; [\varphi]_{\mathcal{M}}[x_k]_{\mathcal{M}} \;=\; Ce_k \;=\; e_{k+1} \;=\; [x_{k+1}]_{\mathcal{M}}$$

for any $1 \le k < n$. That is $\varphi(x_k) = x_{k+1}$ and by induction this yields $\varphi^k(x_1) = x_{k+1}$ for any $0 \le k < n$. For $k = n$ we compute

$$\begin{aligned}
[\varphi(x_n)]_{\mathcal{M}} \;&=\; [\varphi]_{\mathcal{M}}[x_n]_{\mathcal{M}} \;=\; Ce_n \;=\; \sum_{k=1}^{n}(-f[k-1])e_k \\
&=\; \sum_{k=0}^{n-1}(-f[k])e_{k+1} \;=\; \sum_{k=0}^{n-1}(-f[k])[\varphi^k(x_1)]_{\mathcal{M}} \\
&=\; \left[\sum_{k=0}^{n-1}(-f[k])\varphi^k(x_1)\right]_{\mathcal{M}}
\end{aligned}$$

Note that $\varphi(x_n) = \varphi(\varphi^{n-1}(x_1)) = \varphi^n(x_1)$ such that the above equation can also be written as

$$\varphi^n(x_1) \;=\; \varphi(x_n) \;=\; \sum_{k=0}^{n-1}(-f[k])\varphi^k(x_1)$$

In other words that is $fx_1 = f(\varphi)(x_1) = 0$. Also note that the x_k generate M so for any $y \in M$ there are coefficients $b_k \in R$ such that

$$y \;=\; \sum_{k=1}^{n} b_k x_k \;=\; \sum_{k=0}^{n-1} b_{k+1}\varphi^k(x_1)$$

Thus if we define $g(t) := b_1 + b_2 t + \cdots + b_n t^{n-1} \in R[t]$ then by construction we get $gx_1 = g(\varphi)(x_1) = y$. And as y was arbitrary this means that the following map is surjective

$$\varepsilon \;:\; R[t] \;\twoheadrightarrow\; M_\varphi \;:\; g \;\mapsto\; gx_1$$

But it also is $R[t]$-linear, since $\varepsilon(fg) = (fg)x_1 = f(gx_1) = f\varepsilon(g)$. As we have seen $f \in \mathrm{kn}(\varepsilon)$ since $fx_1 = 0$ such that the following map is a well defined homorphism of $R[t]$-modules

$$\bar{\varepsilon} \;:\; R[t]\Big/_{fR[t]} \;\twoheadrightarrow\; M_\varphi \;:\; g + fR[t] \;\mapsto\; gx_1$$

So it remains to prove that this map is injective. But if we let $u := t + fR[t]$ then as $\deg(f) = n$ it is clear, that $\{\, 1, u, \ldots, u^{n-1} \,\}$ generate $R[t]/fR[t]$ as an R-module. Thus any $g + fR[t]$ can be written as

$$g + fR[t] \;=\; \sum_{k=0}^{n-1} b_k u^k$$

for some $b_k \in R$. Now $\bar{\varepsilon}(u^k) = \bar{\varepsilon}(t^k + fR[t]) = t^k x_1 = \varphi^k(x_1) = x_{k+1}$. Hence $g + fR[t]$ is then mapped to

$$\bar{\varepsilon}(g + fR[t]) \;=\; \bar{\varepsilon}\left(\sum_{k=0}^{n-1} b_k u^k\right) \;=\; \sum_{k=0}^{n-1} b_k \bar{\varepsilon}(u^k) \;=\; \sum_{k=0}^{n-1} b_k x_{k+1}$$

If now $\bar{\varepsilon}(g + fR[t]) = 0$ then we can conclude $b_k = 0$ for any $0 \leq k < n$ since the x_k are a basis of M. Therefore $g + fR[t] = 0$ such that we have $\mathrm{kn}(\bar{\varepsilon}) = 0$, which is the injectivety of $\bar{\varepsilon}$.

(iv) (a) $\Longrightarrow$ (b) has been proved in (ii). (b) $\Longrightarrow$ (c) has been proved in (iii). Note that thereby the f in (c) is the same, as in (b). And for (c) $\Longrightarrow$ (a) this is easy to see: Let

$$\Phi \;:\; R[t]\Big/_{fR[t]} \;\xrightarrow{\sim}\; M_\varphi$$

be the isomorphism of $R[t]$-modules and let $x := \Phi(1 + fR[t]) \in M_\varphi$. As Φ is surjective, for any $y \in M_\varphi$ there is some $g \in R[t]$ such that $y = \Phi(g + fR[t]) = g\varphi(1 + fR[t]) = gx$. From this we see that $M_\varphi = R[t]x$ and hence $x \in M_\varphi$ is a cyclic vector.

That is we conclude (a) and hence (b) from the assumption $R[t]/fR[t] \xrightarrow{\sim} M_\varphi$. That is there is some polynomial $g \in R[t]$ such that $[\varphi] = \mathrm{comp}(g)$. But from this we can conclude $R[t]/gR[t] \xrightarrow{\sim} M_\varphi$ again. In particular $R[t]/fR[t] \cong_{\mathsf{m}} R[t]/gR[t]$ such that by (3.83.(ii)) we find $fR[t] = gR[t]$. That is $f \approx g$ and as f and g have also been assumed to be monic, we get $f = g$.

□

Proof of (5.58):

The existence of the invariant ideals has been proved in (5.32.(i)). Now for the properties of this: First of all $E[t]f_{i+1} = \mathrm{ann}(x_{i+1}) \subseteq \mathrm{ann}(x_i) = E[t]f_i$ implies $f_{i+1} \in E[t]f_i$ such that $f_i \mid f_{i+1}$ and this already

is (i). Also note that by (5.32.(i)) we also have $f_r E[t] = \mathrm{ann}(V_\varphi) = \{ f \in E[t] \mid \forall\, x \in V : fx = 0 \}$. By definition of the scalar multiplication in V_φ this is $f(\varphi)(x) = 0$ for any $x \in V$ which is equivalent to $f(\varphi)$. Altogether

$$f_r E[t] \;=\; \mathrm{ann}\big(V_\varphi\big) \;=\; \{ f \in E[t] \mid f(\varphi) = 0 \} \;=\; m_\varphi E[t]$$

That is $f_r \approx m_\varphi$ and as both f_r and m_φ are monic this implies $f_r = m_\varphi$ such that we also have established (ii). Next note, that due to $\mathrm{ann}(x_i) = f_i E[t]$ we generally have the following isomorphy of $E[t]$-modules

$$E[t] \Big/ {}_{f_i E[t]} \;\xrightarrow{\sim}\; : E[t]x_i \;:\; g + f_i E[t] \mapsto g x_i$$

as $f_i E[t] = \mathrm{ann}(x_i) = \mathrm{kn}(g \mapsto g x_i)$. As this isomorphism is E-linear, in particular, this also is an isomorphy of E-vector spaces. Therefore the dimension of $E[t]x_i$ is given to be

$$\dim_E\big(E[t]\, x_i\big) \;=\; \dim_E \Big(E[t] \Big/ {}_{f_i E[t]} \Big) \;=\; \deg(f_i) \;=\; n(i)$$

by (8.10.(i)). In the proof of (iii) and (iv) we reap the harvest of all the propositions above: By (5.56.(i)) any $E[t]x_i$ is φ-invariant. Hence the restriction $\varphi_i : E[t]x_i \to E[t]x_i$ of φ to $E[t]x_i$ is well-defined. Hereby x_i is a cyclic vector of $E[t]x_i$ by (5.57.(i)) and hence we have $[\varphi_i]_{\mathcal{M}_i} = \mathrm{comp}(f)$ for some monic polynomial f by (5.57.(iv)). Thereby $f = f_i$, as $E[t]/f_i E[t] \xrightarrow{\sim} E[t]x_i$ are isomorphic, as $E[t]$-modules and these polynomials are the same. Now we use (5.48.(iii)) to find statement (iii)

$$c_\varphi \;=\; \prod_{i=1}^{r} c_{\varphi_i}$$

As x_i is a cyclic vector for $E[t]x_i$ and this subspace has dimension $n(i)$ over E, we find that $\mathcal{V}_i$ truly is an ordered basis. By (5.57.(ii)) we then find $[\varphi_i]_{\mathcal{V}_i} = \mathrm{comp}(g_i)$ for some monic polynomial g_i of degree $n(i)$ with $g_i x_i = 0$ again. That is $g_i \in \mathrm{ann}(x_i) = f_i E[t]$, and as $\deg(f_i) = n_i$ this implies $f_i \approx g_i$ and as both are monic $g_i = f_i$ again. That is $[\varphi_i]_{\mathcal{V}_i} = \mathrm{comp}(f_i)$ and hence we find (iv)

$$[\varphi]_{\mathcal{V}} \;:\; \bigoplus_{i=1}^{r} [\varphi_i]_{\mathcal{V}_i} \;=\; \bigoplus_{i=1}^{r} \mathrm{comp}(f_i)$$

□

Proof of (5.60):
Statement (i) is just (3.146.(v)) and statement is just (3.160.(i)). Δ_φ is a well-defined homomorphism of R-modules, as it is $\Delta_\varphi = \lambda_t \otimes M + R[t] \otimes \varphi$. And π_φ comes from the R-bilinear map $(f, x) \mapsto fx$ by the universal property of the tensor product. Let us also verify the $R[t]$-linearity of these maps:

$$\begin{aligned}
\Delta_\varphi\big(g(f \otimes x)\big) \;&=\; \Delta_\varphi\big((gf) \otimes x\big) \;=\; (tgf) \otimes x + (gf) \otimes \varphi(x) \\
&=\; g\big((tf) \otimes x + f \otimes \varphi(x)\big) \;=\; g\, \Delta_\varphi\big(f \otimes x\big) \\
\pi_\varphi\big(g(f \otimes x)\big) \;&=\; \pi_\varphi\big((gf) \otimes x\big) \;=\; (gf)x \;=\; g(fx) \;=\; g\, \pi_\varphi\big(f \otimes x\big)
\end{aligned}$$

(iii) The surjectivity of π_φ is clear: Given any $x \in M$ this is contained in the image, as $\pi_\varphi(\mathbf{1} \otimes x) = \mathbf{1}x = \mathbb{1}(x) = x$. Next we prove the injectivity of Δ_φ: By (i) any element of $M_{R[t]}$ can be written as

a finite sum of $t^k \otimes x_k$ uniquely. Now suppose

$$\begin{aligned} 0 &= \Delta_\varphi\left(\sum_{k=0}^{d} t^k \otimes x_k\right) = \sum_{k=0}^{d} \left(t^{k+1} \otimes x_k - t^k \otimes \varphi(x_k)\right) \\ &= \sum_{k=1}^{d+1} t^k \otimes x_{k-1} - \sum_{k=0}^{d} t^k \otimes \varphi(x_k) = t^{d+1} \otimes x_d + \sum_{k=1}^{d} t^k \otimes \left(x_{k-1} - \varphi(x_k)\right) - \mathbf{1} \otimes \varphi(x_0) \end{aligned}$$

As $0 = \sum_k t^k \otimes 0$ as well and the x_k are uniquely determined we find $x_d = 0$ by comparing the tensor-companion of t^{d+1} and for any $k \in 1 \dots n$ also $x_{k-1} = \varphi(x_k)$ by comparing the tensor-companions of t^k. That is $x_{d-1} = \varphi(x_d) = \varphi(0) = 0$ and so on, such that we get $x_k = 0$ for any $k \in 0 \dots d$. That is $\mathsf{kn}(\Delta_\varphi) = 0$ and hence Δ_φ is injective.

(iii) Let us check $\mathsf{im}(\Delta_\varphi) \subseteq \mathsf{kn}(\pi_\varphi)$ next: That is we have to verify $\pi_\varphi \Delta_\varphi = 0$ and for this it suffices to regard elements of the form $t^k \otimes x$, as these generate $M_{R[t]}$. So let us compute

$$\begin{aligned} \pi_\varphi \Delta_\varphi\left(t^k \otimes x\right) &= \pi_\varphi\left(t^{k+1} \otimes x - t^k \otimes \varphi(x)\right) \\ &= t^{k+1}x - t^k\varphi(x) = \varphi^{k+1}(x) - \varphi^k\left(\varphi(x)\right) = 0 \end{aligned}$$

(iii) The exactness of the chain is established, once we prove $\mathsf{kn}(\pi_\varphi) \subseteq \mathsf{im}(\Delta_\varphi)$: To do this let us first prove that for any $k \geq 1$ and any $x \in M$ we have $t^k \otimes x - \mathbf{1} \otimes \varphi^k(x) \in \mathsf{im}(\Delta_\varphi)$. This can be done by a simple telescope sum

$$\begin{aligned} \Delta_\varphi\left(\sum_{r=0}^{k-1} t^{k-1-r} \otimes \varphi^r(x)\right) &= \sum_{r=0}^{k-1} \Delta_\varphi\left(t^{k-1-r} \otimes \varphi^r(x)\right) \\ &= \sum_{r=0}^{k-1} \left(t^{k-r} \otimes \varphi^r(x) - t^{k-1-r} \otimes \varphi^{r+1}(x)\right) \\ &= \sum_{r=0}^{k-1} \left(t^{k-r} \otimes \varphi^r(x)\right) - \sum_{r=1}^{k} \left(t^{k-r} \otimes \varphi^r(x)\right) \\ &= t^k \otimes x - \mathbf{1} \otimes \varphi^k(x) \end{aligned}$$

We use this to prove $x \in \mathsf{im}(\Delta_\varphi)$ for any $x \in \mathsf{kn}(\pi_\varphi)$: If $x = \sum_k t^k \otimes x_k$ then $\pi_\varphi(x) = 0$ means

$$0 = \sum_{k=0}^{d} t^k x_k = \sum_{k=0}^{d} \varphi^k(x_k)$$

But this property enables us to append x to $x + 0$ is such a way that it becomes apparent, that x is contained in the image of Δ_φ using the telescope elements above

$$\begin{aligned} x &= \sum_{k=0}^{d} t^k \otimes x_k = \sum_{k=0}^{d} t^k \otimes x_k - \mathbf{1} \otimes 0 \\ &= \sum_{k=0}^{d} t^k \otimes x_k - \mathbf{1} \otimes \left(\sum_{k=0}^{d} \varphi^k(x_k)\right) \\ &= \sum_{k=0}^{d} \left(t^k \otimes x_k - \mathbf{1} \otimes \varphi^k(x_k)\right) \in \mathsf{im}(\Delta_\varphi) \end{aligned}$$

(iv) If M is generated by $\{ m_i \mid i \in I \}$ as an R-module, then $M_{R[t]}$ is generated by $\{ \mathbf{1} \otimes m_i \mid i \in I \}$ as an $R[t]$-module. As Δ_φ is injective, it becomes an isomorphism, when restricted to its image

$$\Delta_\varphi \;:\; M_{R[t]} \;\xrightarrow{\sim}\; \mathrm{im}(\Delta_\varphi) \;=\; \mathrm{kn}(\pi_\varphi)$$

In particular the generating set $\{ \mathbf{1} \otimes m_i \mid i \in I \}$ of $M_{R[t]}$ is transferred into $\mathrm{kn}(\pi_\varphi)$ under Δ_φ. And as $\Delta_\varphi(\mathbf{1} \otimes m_i) = t \otimes m_i - \mathbf{1} \otimes \varphi(m_i)$ by definition of Δ_φ we find, that the set given in the claim of (iv) truly generates $\mathrm{kn}(\pi_\varphi)$ as an $R[t]$-module.

(v) Let $\mathcal{M} = (m_1, \ldots, m_n)$ be an ordered R-basis of M, then by (ii) $\mathbf{1} \otimes \mathcal{M} := (\mathbf{1} \otimes m_1, \ldots, \mathbf{1} \otimes m_n)$ is an ordered $R[t]$-basis of $M_{R[t]}$. Let $A := [\varphi] \in \mathrm{mat}_n(R)$ be the representation of φ with respect to $\mathcal{M}$, that is for any $j \in 1 \ldots n$ we have

$$\varphi(m_j) \;=\; \sum_{i=1}^{n} a_{i,j} m_i$$

From this we will deduce that the matrix representation of Δ_φ with respect to $\mathbf{1} \otimes \mathcal{M}$ is given by $(t\mathbb{1}_n - A) \in \mathrm{mat}_n(R[t])$ (see below). And from this we immediately get the identity of the determinant: $\det(\Delta_\varphi) = \det(t\mathbb{1}_n - A) = c_\varphi(t)$. So let us verify $[\Delta_\varphi] = (t\mathbb{1}_n - A)$:

$$\begin{aligned}
\Delta_\varphi(\mathbf{1} \otimes m_j) &= t \otimes m_j - \mathbf{1} \otimes \varphi(m_j) \\
&= t \otimes m_j - \mathbf{1} \left(\sum_{i=1}^{n} a_{i,j} m_i \right) \\
&= t\,\mathbf{1} \otimes m_j - \sum_{i=1}^{n} a_{i,j}\,\mathbf{1} \otimes m_i \\
&= \sum_{i=1}^{n} \left(t\delta_{i,j} - a_{i,j} \right) \mathbf{1} \otimes m_i \\
&= \sum_{i=1}^{n} \left[t\mathbb{1}_n - A \right]_{i,j} \mathbf{1} \otimes m_i
\end{aligned}$$

□

Proof of (5.48):

(i) Pick up an ordered basis $\mathcal{M} = (m_1, \ldots, m_r)$ of M and let $\mathcal{N} := (n_1, \ldots, n_r)$ where $n_i := \Phi(m_i)$. As Φ is an isomorphism it is clear that $\mathcal{N}$ is an ordered basis of N. And by construction $\Phi(m_i) = n_i$ we have $[\Phi]^{\mathcal{N}}_{\mathcal{M}} = \mathbb{1}_r$. Thus

$$[\psi]_{\mathcal{N}} \;=\; [\Phi\psi\Phi^{-1}]_{\mathcal{N}} \;=\; [\Phi]^{\mathcal{N}}_{\mathcal{M}}\, [\varphi]_{\mathcal{M}}\, [\Phi^{-1}]^{\mathcal{M}}_{\mathcal{N}} \;=\; \mathbb{1}_r\, [\varphi]_{\mathcal{M}}\, \mathbb{1}_r \;=\; [\varphi]_{\mathcal{M}}$$

That is ψ and φ share the same matrix representation $A := [\varphi]_{\mathcal{M}} = [\psi]_{\mathcal{N}}$ and in particular the same characteristic polynomial $c_\varphi(t) = c_A(t) = c_\psi(t)$.

(i) Let us first prove that $\psi^k = \Phi\varphi^k\Phi^{-1}$ by induction on k: The case $k = 0$ is easy, as $\psi^0 = \mathbb{1}_N$ and $\Phi\varphi^0\Phi^{-1} = \Phi\mathbb{1}_M\Phi^{-1} = \mathbb{1}_N$ in this case. And for the induction step we simply compute

$$\psi^{k+1} \;=\; \psi^k\psi \;=\; \Phi\varphi^k\Phi^{-1}\,\Phi\varphi\Phi^{-1} \;=\; \Phi\varphi^k\varphi\Phi^{-1} \;=\; \Phi\varphi^{k+1}\Phi^{-1}$$

As Φ is R-linear and as the addition and scalar multiplication in $\mathrm{end}(M)$ are point-wise, we find $f(\psi) = f(\Phi\varphi\Phi^{-1}) = \Phi f(\varphi)\Phi^{-1}$ for any polynomial $f \in R[t]$, as for any $y \in N$ we compute

$$\begin{aligned} f(\psi)(y) &= \sum_{k=0}^{\infty} f[k]\psi^k = \sum_{k=0}^{\infty} f[k]\Phi\varphi^k\Phi^{-1}(y) = \left(\sum_{k=0}^{\infty} f[k]\Phi\varphi^k\right)\left(\Phi^{-1}(y)\right) \\ &= \Phi\left(\sum_{k=0}^{\infty} f[k]\varphi^k\right)\left(\Phi^{-1}(y)\right) = \Phi f(\varphi)\left(\Phi^{-1}(y)\right) = \Phi f(\varphi)\Phi^{-1}(y) \end{aligned}$$

In particular we find the equivalence of $f(\psi) = 0 \in \mathrm{end}(N)$ and $f(\varphi) = 0 \in \mathrm{end}(M)$, as for any $y = \Phi(x) \in N$ we have the following equivalence

$$\begin{aligned} f(\sigma)(y) = 0_N &\iff \Phi f(\varphi)\Phi^{-1}(y) = 0_N \\ &\iff f(\varphi)\Phi^{-1}(y) = 0_M \\ &\iff f(\varphi)(x) = 0_M \end{aligned}$$

as Φ is assumed to be bijective. That is the ideals $\mathrm{kn}(f \mapsto f(\psi)) = \{ f \in R[t] \mid f(\psi) = 0_N \}$ and $\mathrm{kn}(f \mapsto f(\varphi)) = \{ f \in R[t] \mid f(\varphi) = 0_M \}$ are identical subsets of $R[t]$. However m_ψ and m_φ are the monic generators of the respective ideal(s) and hence they have to be identical, too.

(ii) First of all $\varphi \mid P$ i well-defined, as $\varphi(P) \subseteq P$ by assumption. Also $\overline{\varphi}$ is well-defined: If $x + P = y + P$ then $y - x \in P$ such that $\varphi(y) - \varphi(x) = \varphi(y - x) \in \varphi(P) \subseteq P$ and therefore $\varphi(y) + P = \varphi(x) + P$.

By assumption P is free, so there is a basis $\{ p_i \mid i \in I \}$ of P. According to (3.99.(iv)) $|I| = \dim(P) \leq \mathrm{rank}(M) < \infty$ as M was assumed to be finitely generated. Thus we may take $I = 1 \ldots r$. By assumption also M/P is free as well, so there is a basis $\{ q_j + P \mid j \in J \}$ of M/P. Thereby $\{ q_j \mid j \in J \}$ is linearly independent, as $\sum_j b_j q_j = 0$ would imply $\sum_j b_j(q_j + P) = 0 + P$ and hence $b_j = 0$ for any $j \in J$. Thus (3.99.(iv)) also implies $|J| < \infty$ and we may take $J = 1 \ldots s$. Then we find, that $\{ p_1, \ldots, p_r \} \cup \{ q_1, \ldots, q_s \}$ is a basis of M, as any $x \in M$ can be uniquely written, as

$$x = \sum_{i=1}^{r} a_i p_i + \sum_{j=1}^{s} b_j q_j$$

where $x + P = \sum_j b_j(q_j + P)$ and $x - \sum_j b_j q_j = \sum_i a_i p_i \in P$. Let us denote $\mathcal{M} := (p_1, \ldots, p_r, q_1, \ldots, q_s)$ and likewise $\mathcal{P} := (p_1, \ldots, p_r)$ and $\mathcal{Q} := (q_1 + P, \ldots, q_s + P)$. Then $\mathcal{M}$ is an ordered basis of M, $\mathcal{P}$ is an ordered basis of P and $\mathcal{Q}$ is an ordered basis of M/P. Since P is invariant under φ we have $\varphi(p_i) \in P = \mathrm{Lh}\{ p_1, \ldots, p_r \}$. Therefore the matrix representation of φ in this basis is of the following form:

$$D := [\varphi]_{\mathcal{M}} = \begin{pmatrix} A & B \\ 0 & C \end{pmatrix} \in \mathrm{mat}_{r+s}(R)$$

For some matrices $A \in \mathrm{mat}_r(R)$, $B \in \mathrm{mat}_{r,s}(R)$ and $C \in \mathrm{mat}_s(R)$. By construction it is clear, that $A = [\varphi \mid P]_{\mathcal{P}}$. But also $[\overline{\varphi}]_{\mathcal{Q}} = C$, as $\overline{\varphi}(q_j + P) = \varphi(q_j) + P$. Thus we may compute the characteristic polynomial of φ by evaluating the characteristic polynomial of D. For the determinant

of the block matrix $t\mathbb{1}_{r+s} - D$ we thereby use (4.58.(i))

$$\begin{aligned} c_D(t) &= \det\big(t\mathbb{1}_{r+s} - D\big) = \det\begin{pmatrix} t\mathbb{1}_r - A & -B \\ 0 & t\mathbb{1}_s - C \end{pmatrix} \\ &= \det(t\mathbb{1}_r - A)\cdot\det(t\mathbb{1}_s - C) = c_A(t)\cdot c_C(t) \end{aligned}$$

As the characteristic polynomials can be computed for *any* basis representation we have $c_\varphi(t) = c_D(t) = c_A(t)\cdot c_C(t) = c_{\varphi|P}(t)\cdot c_{\overline{\varphi}}(t)$.

(iii) For the proof of this statement we use induction on r, the case $r = 1$ being trivial. For $r+1$ let us denote $P := P_{r+1}$ and $Q := P_1 + \cdots + P_r$. Then $M = P \oplus Q$ and in particular we have the isomorphism

$$\Phi : Q \xrightarrow{\sim} M\Big/_P : q \mapsto q + P$$

In particular M/P is free again, as all the P_i admit a basis. Hence the requirements of (ii) are satisfied and we pick up $\overline{\varphi} \in \mathrm{end}(M/P)$. Then for any $q \in Q$ we have $\Phi(\varphi \mid Q)(q) = \varphi(q) + P$ and $\overline{\varphi}\Phi(q) = \overline{\varphi}(q+P) = \varphi(q) + P$ such that $\Phi(\varphi \mid Q) = \overline{\varphi}\Phi$. From this we get $\overline{\varphi} = \Phi(\varphi \mid Q)\Phi^{-1}$ such that (i) implies $c_{\overline{\varphi}}(t) = c_{\varphi|Q}$. By the induction hypothesis for $\varphi \mid Q$ we then get

$$c_\varphi(t) = c_{\varphi|P}(t)\cdot c_{\overline{\varphi}}(t) = c_{\varphi|P}(t)\cdot c_{\varphi|Q}(t) = c_{\varphi|P_{r+1}}(t)\cdot\prod_{i=1}^{r} c_{\varphi_i}(t)$$

(iv) ($\diamondsuit$) This proof is computational, yet a little advanced. It is based on the machinery provided in proposition (5.60), so the reader should familiarize himself with the notation used there.

Now pick up an ordered basis $\mathcal{M} := (m_1, \ldots, m_n)$ of the R-module M. Then by (5.60.(ii)) we also obtain an ordered $R[t]$-basis of $M_{R[t]}$ by $\mathbf{1}\otimes\mathcal{M} := (\mathbf{1}\otimes m_1, \ldots, \mathbf{1}\otimes m_n)$. By assumption, for any $k \in 1\ldots n$, we have $f_k\,\mathbf{1}\otimes m_k = f_k \otimes m_k \in \mathrm{kn}(\pi_\varphi)$, since

$$\pi_\varphi\big(f_k\otimes m_k\big) = f_k m_k = f_k(\varphi)(m_k) = 0(m_k) = 0$$

But by (5.60.(iii)) we have $\mathrm{kn}(\pi_\varphi) = \mathrm{im}(\Delta_\varphi)$ and by (5.60.(iv)) the image of Δ_φ is generated (as an $R[t]$-module) by elements of the form $t\otimes m_j - \mathbf{1}\otimes\varphi(m_j)$. That is there are polynomials $g_{j,k} \in R[t]$ such that

$$f_k\,\mathbf{1}\otimes m_k = \sum_{j=1}^{n} g_{j,k}\left(t\otimes m_j - \mathbf{1}\otimes\varphi(m_j)\right)$$

Let $A = [\varphi]$ be the representation of φ with respect to the basis $\mathcal{M}$. That is $\varphi(m_j) = \sum_i a_{i,j}m_i$ for any $j \in 1\ldots n$. Then we can insert $\varphi(m_j)$ into the equation above

$$\begin{aligned} f_k\,\mathbf{1}\otimes m_k &= \sum_{j=1}^{n} g_{j,k}\left(t\otimes m_j - \mathbf{1}\otimes\left(\sum_{i=1}^{n} a_{i,j}m_i\right)\right) \\ &= \sum_{j=1}^{n} g_{j,k}\left(t\,\mathbf{1}\otimes m_j - \sum_{i=1}^{n} a_{i,j}\,\mathbf{1}\otimes m_i\right) \\ &= \sum_{j=1}^{n} g_{j,k}\sum_{i=1}^{n}\left(\delta_{i,j}t\,\mathbf{1}\otimes m_i - a_{i,j}\,\mathbf{1}\otimes m_i\right) \end{aligned}$$

$$
\begin{aligned}
&= \sum_{j=1}^{n} g_{j,k} \sum_{i=1}^{n} \left(\delta_{i,j} t - a_{i,j}\right) \mathbf{1} \otimes m_i \\
&= \sum_{i=1}^{n} \left(\sum_{j=1}^{n} \left(\delta_{i,j} t - a_{i,j}\right) g_{j,k} \right) \mathbf{1} \otimes m_i
\end{aligned}
$$

Let $G := (g_{j,k}) \in \mathrm{mat}_n(R[t])$ be the matrix composed of the coefficient polynomials $g_{j,k}$ then the equation above tells us that the coefficients of the basis representation of $f_k \mathbf{1} \otimes m_k$ in $\mathbf{1} \otimes \mathcal{M}$ are precisely the coefficients of the matrix multiplication $(t\mathbb{1}_n - A)G$

$$
f_k \mathbf{1} \otimes m_k \;=\; \sum_{i=1}^{n} \left(\sum_{j=1}^{n} [t\mathbb{1}_n - A]_{i,j} [G]_{j,k} \right) \mathbf{1} \otimes m_i \;=\; \sum_{i=1}^{n} \left[\left(t\mathbb{1}_n - A\right) G \right]_{i,k} \mathbf{1} \otimes m_i
$$

Let $F := \mathrm{dia}(f_1, \ldots, f_n)$ be the diagonal matrix of the polynomials f_k, then the left hand side is the basis representation of the k-th row of F. The right hand side is the k-th row of the basis representation of $(t\mathbb{1}_n - A)G$. That is we have found the following identity of matrices

$$
F \;=\; \left(t\mathbb{1}_n - A\right) G
$$

And from this identity, as the determinant is multiplicative, we find that the characteristic polynomial of φ is a factor of the product $f_1 \ldots f_n$, the other being the determinant of G

$$
f_1 \cdot \ldots \cdot f_n \;=\; \det\left(F\right) \;=\; \det\Big(\left(t\mathbb{1}_n - A\right) G\Big) \;=\; \det\left(t\mathbb{1}_n - A\right)\det\left(G\right) \;=\; c_\varphi \det\left(G\right)
$$

(v) Since the row in the diagram is exact φ injective and hence we have an isomorphism $\Phi : L \xrightarrow{\sim} P := \mathrm{im}(\varphi) : x \mapsto \varphi(x)$. And as the diagram commutes we have $\mu\varphi = \varphi\lambda$. Thus if $y = \varphi(x) \in P$ then $\mu(y) = \mu\varphi(x) = \varphi\lambda(x) \in \mathrm{im}(\varphi) = P$. That is $\mu(P) \subseteq P$ and thereby we may regard the map $\mu \mid P$. For this we also get $(\mu \mid P)\Phi = \Phi\lambda$ such that $\mu \mid P = \Phi\lambda\Phi^{-1}$. In particular (i) implies

$$
c_{\mu|P}(t) \;=\; c_\lambda(t)
$$

The exactness of the rows also means $P = \mathrm{im}(\varphi) = \mathrm{kn}(\psi)$ and therefore we obtain another isomorphism

$$
\Psi \;:\; M \Big/ P \;\xrightarrow{\sim}\; N \;:\; y + P \;\mapsto\; \psi(y)
$$

As N is free, so is M/P. That is all the requirements of (ii) for μ with P are satisfied. Therefore we find the split

$$
c_\mu(t) \;=\; c_{\mu|P}(t) \cdot c_{\overline{\mu}}(t)
$$

The commutativity of the right side of the diagram is $\nu\psi = \psi\mu$. Thus $\Psi\overline{\mu}(y + P) = \Psi(\mu(y) + P) = \psi\mu(y)$ and $\nu\Psi(y + P) = \nu\psi(y)$ such that $\Psi\overline{\mu} = \nu\Psi$ as well. Therefore we also found $\nu = \Psi\overline{\mu}\Psi^{-1}$ and by (i)

$$
c_{\overline{\mu}}(t) \;=\; c_\nu(t)
$$

Altogether we have found three equalities of characteristic polynomials that finally yield the desired result: $c_\mu(t) = c_{\mu|P}(t) \cdot c_{\overline{\mu}}(t) = c_\lambda(t) \cdot c_\nu(t)$.

(vi) If $\mathcal{M} = (m_1, \ldots, m_n)$ is an ordered R-basis of M, then according to (3.160.(i)) $\mathcal{M}_S := (1 \otimes m_1, \ldots, 1 \otimes m_n)$ is an ordered S basis of M_S. And if $A = (a_{i,j}) = [\varphi]_{\mathcal{M}}$ is the representation of φ in this basis, then φ_S has the representation $[\varphi_S]_{\mathcal{M}_S} = \alpha(A) := (\alpha(a_{i,j}))$ as we have seen in (3.160.(ii)). In particular

$$c_{\varphi_S}(t) \;=\; \det\big(t\mathbb{1}_n - \alpha(A)\big) \;=\; \det\big(\widetilde{\alpha}(t\mathbb{1}_n - A)\big)$$

Now $\widetilde{\alpha}$ is a homomorphism of rings, since α was assumed to be such. And as the determinant can be computed explicitly by a combination of sums and products, we can pull $\widetilde{\alpha}$ out of the determinant (this is (4.55).(vi)). Doing this we arrive at

$$c_{\varphi_S}(t) \;=\; \det\big(\widetilde{\alpha}(t\mathbb{1}_n - A)\big) \;=\; \widetilde{\alpha}\big(\det(t\mathbb{1}_n - A)\big) \;=\; \widetilde{\alpha}\big(c_\varphi(t)\big)$$

□

Proof of (5.52):

- Let us first prove the equivalences of (a), (b) and (c) in case of a general commutative ring R: Starting with (a) there is a basis $\{ m_1, \ldots, m_n \}$ such that $\varphi(m_i) = \lambda_i m_i$. We order this basis arbitrarily, say $\mathcal{M} := (m_1, \ldots, m_n)$. Then $\varphi(m_i) = \lambda_i m_i$ tells us that $[\varphi(m_i)]_{\mathcal{M}} = \lambda_i e_i$. That means $[\varphi]_{\mathcal{M}} = \mathrm{dia}(\lambda_1, \ldots, \lambda_n)$ is a diagonal matrix, such that we have arrived at (b). Now consider any (other) ordered basis $\mathcal{M}'$ of M. We want to prove that $[\varphi]_{\mathcal{M}'}$ is diagonizable and start with a diagonal matrix $D = [\varphi]_{\mathcal{M}}$. By change of base (4.42.(v)) we let $T := [\mathbb{1}_M]^{\mathcal{M}'}_{\mathcal{M}}$ and hence find

$$[\varphi]_{\mathcal{M}'} \;=\; T\,D\,T^{-1} \;\approx\; D$$

That is we have arrived at (c): $[\varphi]_{\mathcal{M}'}$ is diagonizable. Now we need to return to (a). That is we have $A = [\varphi]_{\mathcal{M}'} = TDT^{-1}$ for some diagonal matrix $D = \mathrm{dia}(\lambda_1, \ldots, \lambda_n)$ and need to find a basis $\{ m_1, \ldots, m_n \}$ of M such that $\varphi(m_i) = \lambda_i m_i$. Let $\mathcal{M}' = (m'_1, \ldots, m'_n)$ and $A = (a_{i,j})$, likewise $T = (t_{i,j})$ and for any $j \in 1 \ldots n$ define

$$m_j \;:=\; \sum_{i=1} t_{i,j}\, m'_i$$

As T is invertible (4.42.(iii)) tells us that $\mathcal{M} := (m_1, \ldots, m_n)$ truly is an ordered basis of M and that $T = [\mathbb{1}_M]^{\mathcal{M}'}_{\mathcal{M}}$ and $T^{-1} = [\mathbb{1}_M]^{\mathcal{M}}_{\mathcal{M}'}$ are the matrices of base change. Thus we have

$$[\varphi(m_j)]_{\mathcal{M}} \;=\; [\varphi]_{\mathcal{M}}[m_j]_{\mathcal{M}} \;=\; [\mathbb{1}_M]^{\mathcal{M}}_{\mathcal{M}'}\,[\varphi]_{\mathcal{M}'}\,[\mathbb{1}_M]^{\mathcal{M}'}_{\mathcal{M}}[m_j]_{\mathcal{M}} \;=\; T^{-1}\,A\,T\,e_j \;=\; De_j \;=\; \lambda_j e_j$$

Returning from the basis representation of $\mathcal{M}$ (using $R^n \xrightarrow{\sim} M : a \mapsto a_1 m_1 + \ldots a_n m_n$ the inverse isomorphism) we see $\varphi(m_j) = \lambda_j m_j$ which is (a). In the end we have come full circle.

- Let us now assume, that R is an integral domain, then we will prove (a) $\Longrightarrow$ (e), (e) $\Longrightarrow$ (d) is trivial and we will return by proving (d) $\Longrightarrow$ (e) and (e) $\Longrightarrow$ (c). As (a) and (c) are equivalent, this suffices. The easy part is from (a) to (e):

 If $\{ m_1, \ldots, m_n \}$ is a basis of M such that $\varphi(m_j) = a_j m_j$ we have already seen in example (5.36)

that for any $\lambda \in R$ the eigenspace of φ to λ is given to be

$$\mathrm{Eig}_\varphi(\lambda) \;=\; \mathrm{Lh}\{\, m_j \mid j \in 1 \ldots n,\, a_j = \lambda \,\}$$

Let us denote the distinct elements of the a_j by λ_i again, that is $\{\, a_1, \ldots, a_n \,\} = \{\, \lambda_1, \ldots, \lambda_r \,\}$. Then it is clear that we get a partition of $\{\, m_1, \ldots, m_n \,\} = \mathcal{M}_1 \cup \cdots \cup \mathcal{M}_r$ by taking

$$\mathcal{M}_i \;:=\; \left\{\, m_j \mid j \in 1 \ldots n,\, a_j = \lambda_i \,\right\}$$

and as the $\mathcal{M}_i$ are linearly independent and generate $\mathrm{Eig}_\varphi(\lambda_i)$ they even are a basis of the respective $\mathrm{Eig}_\varphi(\lambda_i)$. In particular any $\mathrm{Eig}_\varphi(\lambda_i)$ is a free sub-module and we have decomposed into an inner direct sum

$$M \;=\; \bigoplus_{i=1}^{r} \mathrm{Eig}_\varphi(\lambda_i)$$

This is (e) and in particular M is the sum of the eigenspaces, which is (d). Just to be sure: Any $x \in M$ can be expressed (in a unique way), as a sum of the form

$$x \;=\; \sum_{j=1}^{n} x_j m_j \;=\; \sum_{i=1}^{r} \sum_{m_j \in \mathcal{M}_i} x_j m_j$$

We now want to prove (e) from (d), that is we have to prove that the sum is direct, automatically, as we deal with eigenspaces. For ease of notation consider some

$$x_1 \;\in\; \mathrm{Eig}_\varphi(\lambda_1) \cap \sum_{i=2} \mathrm{Eig}_\varphi(\lambda_i)$$

That is there are some $x_i \in \mathrm{Eig}_\varphi(\lambda_i)$ (for $i \in 2 \ldots r$) such that $x_1 = x_2 + \cdots + x_r$. If we had $x_1 \neq 0$ then there would have to be one or more $x_i \neq 0$ for $i \in 2 \ldots r$. Yet $1 \neq 0 \in R$ and by (5.37.(iv)) non-zero x_i would be linearly independent. Thus we find $x_1 = 0$ and hence conclude (e) again.

It remains to prove (c) from (e): As the eigenspaces $M_i := \mathrm{Eig}_\varphi(\lambda_i)$ are free by assumption (e) we can choose bases $\mathcal{M}_i = \left\{\, m_{i,j} \mid j \in 1 \ldots s(i) \,\right\}$ for M_i each. This enables us to decompose M further, into the inner direct sum

$$M \;=\; \bigoplus_{i=1}^{r} M_i \;=\; \bigoplus_{i=1}^{r} \bigoplus_{j=1}^{s(i)} R m_{i,j}$$

As $m_{i,j} \in M_i$ we get $\varphi(m_{i,j}) = \lambda_i m_{i,j} \in R m_{i,j}$ which means that all the $R m_{i,j}$ are invariant under φ. And of course $R m_{i,j}$ is free, as $\left\{\, m_{i,j} \,\right\}$ is its basis. In particular we find that $\mathcal{M} := \left\{\, m_{i,j} \mid i \in 1 \ldots r,\, j \in 1 \ldots s(i) \,\right\}$ is a basis of M and hence $s(1) + \cdots + s(r) = n$. Let $A := [\varphi]_{\mathcal{M}}$ be the representation of φ with respect to this basis. By (4.46.(iii)) we find that

$$A \;\approx\; D \;:=\; A_1 \oplus \cdots \oplus A_n$$

where any A_j is a matrix of size 1. Clearly D is a diagonal matrix, by construction and hence A is similar to a diagonal matrix. If now $\mathcal{M}'$ is any other ordered basis of M, then by (4.42.(v)) $[\varphi]_{\mathcal{M}'}$

is similar to $A = [\varphi]_{\mathcal{M}}$, as well. Hence $[\varphi]_{\mathcal{M}'}$ is diagonizable, as $\approx$ is a transitive relation:

$$[\varphi]_{\mathcal{M}'} \approx [\varphi]_{\mathcal{M}} \text{ and } [\varphi]_{\mathcal{M}} \approx D \implies [\varphi]_{\mathcal{M}'} \approx D$$

- Let us assume R is a field, that we have to prove that (f) and (g) imply (a). In this item we start with (g) $\implies$ (a), that is we assume that the minimal polynomial m_φ splits into *distinct* factors

$$m_\varphi(t) = (t-\lambda_1)(t-\lambda_2)\dots(t-\lambda_r)$$

We will prove, that (a) under this assumption, by induction on the dimension $n := \dim(M)$ of M as an R-vector-space. For $n = 1$ any endomorphism satisfies (a), as $\varphi(a) = \lambda a$ for $\lambda = \varphi(1)$. So let us assume $n > 1$ and proceed by defining

$$L_1 := \operatorname{im}(\varphi - \lambda_1 \mathbb{1})$$

If $L_1 = 0$ then $\varphi = \lambda_1 \mathbb{1}$ and hence we are done already. Thus we are only concerned with $L_1 \neq 0$. First of all, by the dimension formula (3.68.(iii)) we have

$$\dim(L_1) = \dim(V) - \dim\big(\ker(\varphi - \lambda_1\mathbb{1})\big) = n - \mathrm{GM}_\varphi(\lambda_1) < 1$$

Also L_1 is φ-invariant: Consider any $y := \varphi(x) - \lambda_1 x \in L_1$ then $\varphi(y) = \varphi(\varphi - \lambda_1\mathbb{1})(x) = (\varphi - \lambda_1\mathbb{1})\varphi(x)$ and this is the image of $\varphi(x)$ under $\varphi - \lambda_1\mathbb{1}$ and hence $y \in L_1$ again. Therefore the following endomorphism on L_1 is well-defined

$$\varphi_1 : L_1 \to L_1 : x \mapsto \varphi(x)$$

Now, for any $i \in 1\dots r$ let $x_i \neq 0$ be an eigenvector of φ to the eigenvalue λ_i. That is $\varphi(x_i) = \lambda_i x_i$. Then we define $y_i := \varphi(x_i) - \lambda_1 x_i \in L_1$ and claim that y_i is an eigenvector of φ_1 to the eigenvalue λ_i for any $i \in 2\dots r$. This is a simple computation

$$\begin{aligned} y_i &= \varphi(x_i) - \lambda_1 x_i = \lambda_i x_i - \lambda_1 x_i = (\lambda_i - \lambda_1)x_i \\ \varphi_1(y_i) &= \varphi(y_i) = (\lambda_i - \lambda_1)\varphi(x_i) = \lambda_i(\lambda_i - \lambda_1)x_1 = \lambda_i y_i \end{aligned}$$

That is we generally have $\varphi(y_i) = y_i$ and as the λ_i are distinct, we also have $\lambda_i - \lambda_1 \neq 0$ for $i \in 2\dots r$ such that we also have $y_i \neq 0$. This implies $\lambda_i \in \operatorname{Spec}(\varphi_1)$, as we have found the eigenvector y_i. Let us now prove that the minimal polynomial of φ_1 is given to be

$$m_1(t) := (t-\lambda_2)\dots(t-\lambda_r)$$

As we have seen $\lambda_i \in \operatorname{Spec}(\pi_1)$ for any $i \in 2\dots r$ we get $m_{\varphi_1}(\lambda_i) = 0$ by (5.46.(iv)). In particular $(t-\lambda_i) \mid m_{\varphi_1}$ and as these are distinct prime elements of (the PID) $R[t]$ we find $m_1 \mid m_{\varphi_1}$. Conversely consider any $y = \varphi(x) - \lambda_1 x \in L_1$. Then we find

$$\begin{aligned} m_1(\varphi)(y) &= (\varphi-\lambda_2)\dots(\varphi-\lambda_r)(\varphi-\lambda_1)(x) \\ &= (\varphi-\lambda_1)(\varphi-\lambda_2)\dots(\varphi-\lambda_r)(x) \end{aligned}$$

$$= \quad m_\varphi(\varphi)(x) \;=\; 0$$

And as $m_1(\varphi)(y) = 0$ is true for any $y \in L_1$ this is $m_1(\varphi) = 0$. By definition of the minimal polynomial this means $m_{\varphi_1} \mid m_1$ such that together we have $m_{\varphi_1} \approx m_1$. Yet as both polynomials are monic, this is $m_{\varphi_1} = m_1$. In particular the minimal polynomial of φ_1 splits into *distinct* factors

$$m_{\varphi_1}(t) \;:=\; \big(t-\lambda_2\big)\dots\big(t-\lambda_r\big)$$

and as $\dim(L_1) < \dim(M) = n$ we may use the induction hypothesis on φ_1: There is a basis $\{\, u_1,\dots,u_m \,\}$ of L_1 consisting of eigenvectors of φ. As we already know the eigenvalues of φ this means that for any $1 \le i \le m$ we have $\varphi(u_i) = \mu_i$ for some $\mu_i \in \{\, \lambda_2,\dots,\lambda_r \,\}$. Recall that by the dimension formula above we know that $\dim(\mathrm{Eig}_\varphi(\lambda_1)) = n - m$. That is we may choose another basis $\{\, u_{m+1},\dots,u_n \,\}$ of $\mathrm{Eig}_\varphi(\lambda_1)$. In particular we get $\varphi(u_i) = \lambda_i u_i$ for any $m < i \le n$ and hence

$$\{\, u_1,\dots,u_m \,\} \cap \{\, u_{m+1},\dots,u_n \,\} \;=\; \emptyset$$

as any u in the intersection would satisfy $\varphi(u) = \lambda_1 u$ and $\varphi(u) = \lambda_i u$ for some $i \in 2\dots r$. But this is absurd, as $u \neq 0$ (0 never is part of a basis) and $\lambda_1 \neq \lambda_i$. We will now prove that $\{\, u_1,\dots,u_n \,\}$ is linearly independent. That is we assume

$$x \;=\; \sum_{i=1}^{n} a_i u_i \;=\; 0$$

for some $a_i \in R$ and have to verify $a_i = 0$ for all $i \in 1\dots n$. To do this apply $\varphi - \lambda_1 \mathbb{1}$ to x and recall that $\varphi(u_i) = \mu_i u_i$ for $i \le m$ and $\varphi(u_i) = \lambda_1 u_i$ for $i > m$. Using this we compute

$$\begin{aligned}
(\varphi - \lambda_1 \mathbb{1})(x) &= \sum_{i=1}^{n} a_i\big(\varphi(u_i) - \lambda_1 u_i\big) \\
&= \sum_{i=1}^{m} a_i\big(\varphi(u_i) - \lambda_1 u_i\big) \\
&= \sum_{i=1}^{m} a_i\big(\mu_i u_i - \lambda_1 u_i\big) \\
&= \sum_{i=1}^{m} a_i\big(\mu_i - \lambda_1\big) u_i
\end{aligned}$$

As $\{\, u_1,\dots,u_m \,\}$ is linearly independent we find $a_i(\mu_i - \lambda_1) = 0$ for any $i \le m$. But $\mu_i - \lambda_1 \neq 0$ such that this means $a_i = 0$. Thus $x = 0$ has been reduced to $a_{m+1}u_{m+1} + \dots + a_n u_n = 0$ in the first place. And as $\{\, u_{m+1},\dots,u_n \,\}$ is linearly independent, as well, this also means $a_i = 0$ for any $i > m$. Altogether $\{\, u_1,\dots,u_n \,\}$ is a linearly independent subset containing $n = \dim(M)$ elements. By (3.66.(viii)) this means, that $\{\, u_1,\dots,u_n \,\}$ is a basis of M and as any u_i is an eigenvector of φ we have finally arrived at (a).

- The one implication left to prove is (f) $\implies$ (a): But in case of a field R this is a no-brainer: By assumption the dimension of M equals the sum of the dimensions of the eigenspaces $\mathrm{Eig}_\varphi(\lambda_i)$. So for any $i \in 1\dots r$ choose a basis $\mathcal{M}_i \subseteq \mathrm{Eig}_\varphi(\lambda_i)$. In particular $\mathcal{M}_i$ consists of eigenvectors and

by definition $\#\mathcal{M}_i = \mathrm{GM}_\varphi(\lambda_i)$. Now let

$$\mathcal{M} \;:=\; \bigcup_{i=1}^{r} \mathcal{M}_i$$

Then by (5.37.(v)) $\mathcal{M}$ is linearly independent again. And by assumption we have $\#\mathcal{M} = \dim(M)$. Hence by (3.66.(viii)) $\mathcal{M}$ is a basis of M, that consists of eigenvectors of φ and this is (a) already.

□

Proof of (5.49):
By Cayley-Hamilton (5.44.(ii)) we have $c_\varphi(\varphi) = 0$ and hence $m_\varphi \mid c_\varphi$ by property (3) in the definition of the minimal polynomial. But also $m_\varphi(\varphi) = 0$, by property (1), so by the theorem of Fitting (5.48.(iv)) (using $f_k = m_\varphi$ for any $k \in 1 \dots n$) we also have $c_\varphi \mid m_\varphi^n$.
If $p \in R[t]$ is prime such that $p \mid m_\varphi$ then $m_\varphi \mid c_\varphi$ yields $p \mid c_\varphi$, as the divides relation is transitive. Conversely, if $p \mid c_\varphi$ then $c_\varphi \mid m_\varphi^n$ yields $p \mid m_\varphi^n$. But as p is prime, this means $p \mid m_\varphi$, too. □

Proof of (3.92):
First of all it is clear, that is suffices to check the implication (a) $\implies$ (b), due to the symmetry of the equivalence. That is we assume that to top sequence of M's is a complex, resp. an exact chain.
It also suffices to check the case $n = 2$, that is we concern ourselves with the complex $M_0 \to M_1 \to M_2$ and prove that $N_0 \to N_1 \to N_2$ is a complex, respectively its exactness at N_1. For larger chains the arguments can be repeated at any module N_k where $1 \leq k \leq n-1$.
Due to the commutativity of the diagrams we have $\psi_1 = \Phi_1\varphi_1\Phi_0^{-1}$ and $\psi_2 = \Phi_2\varphi_2\Phi_1^{-1}$ respectively. And by assumption that $M_0 \to M_1 \to M_2$ is a complex, we also know $\varphi_2\varphi_1 = 0$. But from this it is easy to see, that also

$$\psi_2\psi_1 \;=\; \Phi_2\varphi_2\Phi_1^{-1}\Phi_1\varphi_1\Phi_0^{-1} \;=\; \Phi_2\varphi_2\varphi_1\Phi_0^{-1} \;=\; \Phi_2 0\Phi_0^{-1} \;=\; 0$$

So let us now assume $M_0 \to M_1 \to M_2$ even is exact, in order to prove the exactness of $N_0 \to N_1 \to N_2$ it suffices to check $\ker(\psi_2) \subseteq \operatorname{im}(\psi_1)$, as the converse inclusion has just been shown. Thus consider any $n_1 \in \ker(\psi_2) \subseteq N_1$ and let $m_1 := \Phi_1^{-1}(n_1)$. Then we find

$$\varphi_2(m_1) \;=\; \Phi_2^{-1}\psi_2\Phi_1(m_1) \;=\; \Phi_2^{-1}\psi_2(n_1) \;=\; \Phi_2^{-1}(0) \;=\; 0$$

That is $m_1 \in \ker(\varphi_2) = \operatorname{im}(\varphi_1)$ and hecne there is some $m_0 \in M_0$ such that $\varphi_1(m_0) = m_1$. Now let $n_0 := \Phi_0(m_0)$ then we conversely find

$$\psi_1(n_0) \;=\; \Phi_1\varphi_1\Phi_0^{-1}(n_0) \;=\; \Phi_1\varphi_1(m_0) \;=\; \Phi_1(m_1) \;=\; n_1$$

That is $n_1 \in \operatorname{im}(\psi_1)$ and as n_1 has been chosen arbitrarily we have truly established $\ker(\psi_2) \subseteq \operatorname{im}(\psi_1)$ as claimed. □

Proof of (3.93):
In order to prove the left-exactness of the push-forward we have to check two things: φ_* is injective and $\operatorname{im}(\varphi_*) = \ker(\psi_*)$. The injectivity is easy however: suppose $\varphi f_1 = \varphi f_2$ for some homomorphisms f_1, $f_2 \in \mathcal{L}(M, U)$. That is for any $m \in M$ we get $\varphi f_1(m) = \varphi f_2(m)$, but as φ is injective by assumption this means $f_1(m) = f_2(m)$ and hence $f_1 = f_2$, since $m \in M$ has been arbitrary. Also the inclusion

$\mathrm{im}(\varphi_*) \subseteq \mathrm{kn}(\psi_*)$ is easy: By assumption we have $\mathrm{im}(\varphi) = \mathrm{kn}(\psi)$ and hence $\psi\varphi = 0$. So if we start with some $f \in \mathcal{L}(M,U)$ and compute $\psi_*(\varphi_*(f)) = \psi\varphi f = 0f = 0$ we truly find $\varphi_*(f) \in \mathrm{kn}(\psi_*)$. Finally for $\mathrm{kn}(\psi_*) \subseteq \mathrm{im}(\varphi_*)$ we are given some $g \in \mathcal{L}(M,V)$ such that $\psi g = 0$ and need to find some $f \in \mathcal{L}(M,U)$ such that $\varphi f = g$. But $\psi g = 0$ is just $\mathrm{im}(g) \subseteq \mathrm{kn}(\psi) = \mathrm{im}(\varphi)$ again and hence the map $f = \varphi^{-1}g$ is well-defined, since φ is injective.
In order to prove the left-exactness of the pull-back we have to check two things: ψ^* is injective and $\mathrm{im}(\psi^*) = \mathrm{kn}(\varphi^*)$. The injectivity is easy however: suppose $h_1\psi = h_2\psi$ for some homomorphisms h_1, $h_2 \in \mathcal{L}(W,M)$. Since ψ is surjective by assumption, for any $w \in W$ there is some $v \in V$ such that $\psi(v) = w$. And using this we can compute

$$h_1(w) \;=\; h_1\psi(v) \;=\; h_2\psi(v) \;=\; h_2(w)$$

And since w has been arbitrary this means $h_1 = h_2$. The inclusion $\mathrm{im}(\psi^*) \subseteq \mathrm{kn}(\varphi^*)$ is easy as well: We have $\mathrm{im}(\varphi) = \mathrm{kn}(\psi)$ by assumption and in particular $\psi\varphi = 0$. Thus for any $h \in \mathcal{L}(W,M)$ we get $\varphi^*(\psi^*(h)) = h\psi\varphi = h0 = 0$. Finally for $\mathrm{kn}(\varphi^*) \subseteq \mathrm{im}(\psi^*)$ we are given some $g \in \mathcal{L}(V,M)$ such that $g\varphi = 0$ and need to find some $h \in \mathcal{L}(W,M)$ such that $g = h\psi$. But this h can be defined explicitly: given any $w \in W$ choose some $v \in V$ such that $\psi(v) = w$ [which is possible, since ψ is surjective] and let

$$h(w) \;:=\; g(v)$$

Of course we need to check the well-definedness of h, that is consider any two v_1 and $v_2 \in V$ such that $\psi(v_1) = \psi(v_2)$. That is $v_2 - v_1 \in \mathrm{kn}(\psi) = \mathrm{im}(\varphi)$ and hence there is some $u \in U$ such that $\varphi(u) = v_2 - v_1$. In other words $v_2 = v_1 + \varphi(u)$ and thereby we find

$$g(v_2) \;=\; g(v_1 + \varphi(u)) \;=\; g(v_1) + g\varphi(u) \;=\; g(v_1) + 0$$

We also need to check, that $h : W \to M$ is R-linear. But if $v \in V$ satisfies $\psi(v) = w$, then clearly $\psi(av) = a\psi(v) = aw$ and hence $h(aw) = g(av) = ag(v) = ah(w)$. Likewise for $\psi(v_k) = w_k$ we see $\psi(v_1 + v_2) = \psi(v_1) + \psi(v_2) = w_1 + w_2$ and hence $h(w_1 + w_2) = g(v_1 + v_2) = g(v_1) + g(v_2) = h(w_1) + h(w_2)$. Hence we have found our $h \in \mathcal{L}(W,M)$ that satisfies $\psi^*(h) = h\psi = g$. □

Proof of (3.94):
It suffices to check the case $n = 2$, that is we concern ourselves with the chain $M_0 \to M_1 \to M_2$ and prove its exactness at M_1. For larger chains the arguments can be repeated at any module M_k where $1 \leq k \leq n-1$.

(i) First of all take $L = M_0$, by assumption we have $0 = (\varphi_2)_*(\varphi_1)_*(\mathbb{1}) = \varphi_2\varphi_1$ and hence $\mathrm{im}(\varphi_1) \subseteq \mathrm{kn}(\varphi_2)$. For the converse inclusion regard $L = \mathrm{kn}(\varphi_2)$ and the inclusion $\iota : L \to M_1 : k \mapsto k$. Then, as k is in the kernel of φ_2 we find $(\varphi_2)_*(\iota)(k) = \varphi_2\iota(k) = \varphi_2(k) = 0$ and hence $(\varphi_2)_*(\iota) = 0$. But since $\iota \in \mathrm{kn}((\varphi_2)_*) = \mathrm{im}((\varphi_1)_*)$ there has to be some $\alpha \in \mathcal{L}(L, M_0)$ such that $\iota = (\varphi_1)_*(\alpha) = \varphi_1\alpha$. If we now take any $k \in L = \mathrm{kn}(\varphi_2)$ then this means $k = \iota(k) = \varphi_1\alpha(k) \in \mathrm{im}(\varphi_1)$. Thus we have also established $\mathrm{kn}(\varphi_2) \subseteq \mathrm{im}(\varphi_1)$.

(ii) Now take $N = M_2$, by assumption we have $0 = (\varphi_1)^*(\varphi_2)^*(\mathbb{1}) = \varphi_2\varphi_1$ and hence $\mathrm{im}(\varphi_1) \subseteq \mathrm{kn}(\varphi_2)$ again. For the converse inclusion regard $N = M_1/\mathrm{im}(\varphi_1)$ and $\varrho : M_1 \to N : y \mapsto y + \mathrm{im}(\varphi_1)$ the canonocal epimorphism. Then for any $x \in M_0$ we find $(\varphi_1)^*(\varrho)(x) = \varrho\varphi_1(x) =$

$\varphi_1(x) + \mathrm{im}(\varphi_1) = 0$ and hence $(\varphi_1)^*(\varrho) = 0$ which is $\varrho \in \mathrm{kn}((\varphi_1)^*) = \mathrm{im}((\varphi_2)^*)$ by assumption, again. That is there is some $\gamma \in \mathcal{L}(M_2, N)$ such that $\varrho = (\varphi_2)^*(\gamma) = \gamma\varphi_2$. Thus if $k \in \mathrm{kn}(\varphi_2)$, then $k + \mathrm{im}(\varphi_1) = \varrho(k) = \gamma\varphi_2(k) = \gamma(0) = 0$ such that $k \in \mathrm{im}(\varphi_1)$. Thus we have also established $\mathrm{kn}(\varphi_2) \subseteq \mathrm{im}(\varphi_1)$.

□

Proof of (3.45):

(i) Suppose $M \neq 0$, as M is finitely generated, the sub-module $0 \leq_{\mathfrak{m}} M$ is cofinite. Hence by (3.18) there is a maximal sub-module $Q \leq_{\mathfrak{m}} M$ such that $P \subseteq Q \subset M$. As Q is maximal, M/Q is a non-zero, simple R-module [$M/Q \neq 0$, as $Q \neq M$ and by the correspondence theorem (3.16.(ii)): consider a sub-module $U/Q \leq_{\mathfrak{m}} M/Q$, then $U \leq_{\mathfrak{m}} M$ satisfies $Q \subseteq U \subseteq M$ and hence $Q = U$ or $U = M$ due to the maximality of Q]. Therefore

$$\mathfrak{m} := \mathrm{ann}_R\left(M \big/ Q\right)$$

is a maximal ideal $\mathfrak{m} \in \mathrm{Smax}(R)$, according to (3.24.(i)). By definition of $\mathfrak{m}$ we have $ax + Q = a(x + Q) = 0 + Q$ for any $a \in \mathfrak{m}$ and $x \in M$. That is $ax \in Q$ and hence $\mathfrak{m}M \subseteq Q$. Now by assumption we get $Q \subseteq M = \mathfrak{m}M \subseteq Q$. But that is $Q = M$ in contradiction to $Q \neq M$, such that the assumption $M \neq 0$ must have been false.

(ii) By (3.40.(v)) we know that $\mathfrak{m}(M/P)$ equals $(\mathfrak{m}M + P)/P$ and hence we have the following identities (by the assumptions on P)

$$\mathfrak{m}\left(M \big/ P\right) = \mathfrak{m}M + P \big/ P = M \big/ P$$

for any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} R$. Yet as P is cofinite the quotient module M/P is finitely generated. Hence we may use (i) to find $M/P = 0$ and this is nothing but $M = P$.

(iii) If φ is surjective, then $\varphi/\mathfrak{m}$ is surjective for any ideal $\mathfrak{m} \subseteq R$, as we have seen in (3.40.(vii)). Conversely if $\varphi/\mathfrak{m}$ is surjective, then for any $y \in N$ there is some $x \in M$ such that $\varphi(x) + \mathfrak{m}N = y + \mathcal{M}N$. That is there is some $z \in \mathfrak{m}N$ such that $y = \varphi(x) + z \in \mathrm{im}(\varphi) + \mathfrak{m}N$. And as $y \in N$ has been arbitrary, this means $N = \mathrm{im}(\varphi) + \mathfrak{m}N$. As $\mathrm{im}(\varphi)$ is cofinite and this is tru for any maximal ideal $\mathfrak{m}$, we may invoke (ii) to find $\mathrm{im}(\varphi) = N$, but this is nothing but the surjectivity of φ.

(iv) If φ is bijective, then $\varphi/\mathfrak{m}$ is bijective for any ideal $\mathfrak{m} \subseteq R$, as we have seen in (3.40.(vii)). Conversely: as M is finitely generated, the zero-module $0 \leq_{\mathfrak{m}} M$ is cofinite and hence also $\mathrm{im}(\varphi) \leq_{\mathfrak{m}} M$ is cofinite. So by (iii) we already know, that φ is surjective, as the $\varphi/\mathfrak{m}$ are surjective (even bijective). But a surjective endomorphism of a finitely generated R-module is bijective by (5.44).

□

Proof of (3.83):

(i) Suppose I and J have the same cardinality, by definition this means, that there is a bijection $\sigma : I \to J$. And by construction $M := R^{\oplus I}$ has the canoncial basis $e_k = (\delta_{i,k}) \in M$, where $k \in I$.

That is the k-th component of e_k is 1, all others ($i \neq k$) are 0. Likewise we denote the canonical basis of $N := R^{\oplus J}$ by $f_l = (\delta_{j,l}) \in N$, where $l \in J$. This clearly gives rise to a well-defined homomorphism of R-modules:

$$\varphi \ : \ M \to N \ : \ \sum_{i \in I} a_i e_i \mapsto \sum_{i \in I} a_i f_{\sigma(i)}$$

As σ is surjective and $\left\{ f_j \mid j \in J \right\}$ generates N we see that Φ is surjective. Suppose $\Phi(a_i) = 0$, as σ is injective and $\left\{ f_j \mid j \in J \right\}$ is R-linearly independent this means that $a_i = 0$ for any $i \in I$. This is $\mathrm{kn}(\Phi) = 0$ and hence Φ also is injective. Altogether Φ is an isomorphism.

It remains to prove the converse implication, that is we suppose that $M := R^{\oplus I}$ and $N := R^{\oplus J}$ are isomorphic. As R is a non-zero, commutative ring we may use (2.4.(ii)) to pick up a maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ of R (containing $0 \subset R$). Then, as $\mathfrak{m}$ is maximal, $F := R/\mathfrak{m}$ is a field.

As we have seen in (3.41) the quotient $M/\mathfrak{m}M$ is isomorphic to $F^{\oplus I}$, by virtue of the following isomorphism

$$F^{\oplus I} \xrightarrow{\sim} R^{\oplus I} \Big/ \mathfrak{m}R^{\oplus I} \ : \ (b_i + \mathfrak{m}) \mapsto (b_i) + \mathfrak{m}R^{\oplus I}$$

In complete analogy we find an isomorphism of F-vector-spaces between $F^{\oplus J}$ and the quotient $N/\mathfrak{m}N$. Now, as $M \cong_{\mathfrak{m}} N$ are isomorphic (by assumption), so are the quotient modules $M/\mathfrak{m}M \cong_{\mathfrak{m}} N/\mathfrak{m}N$, by virtue of (3.40.(vii)). And therefore we find a chain of isomorphies of F-vector-spaces connecting

$$F^{\oplus I} \ \cong_{\mathfrak{m}} \ R^{\oplus I} \Big/ \mathfrak{m}R^{\oplus I} \ \cong_{\mathfrak{m}} \ R^{\oplus J} \Big/ \mathfrak{m}R^{\oplus J} \ \cong_{\mathfrak{m}} \ F^{\oplus J}$$

Clearly isomorphic modules have the same dimension (the isomorphism transfers bases). And as $F^{\oplus I}$ has dimension $|I|$ (using the canonical basis) altogether we find

$$|I| \ = \ \dim(F^{\oplus I}) \ = \ \dim(F^{\oplus J}) \ = \ |J|$$

(ii) Let $\Phi : R/\mathfrak{a} \to R/\mathfrak{b}$ be the isomorphism of R-modules, that we assumed to exist. Further let $v + \mathfrak{b} := \Phi(1 + \mathfrak{a})$ and $u + \mathfrak{a} := \Phi^{-1}(1 + \mathfrak{b})$. Then - as Φ is R-linear - we get

$$\Phi(uv + \mathfrak{a}) \ = \ v\Phi(u + \mathfrak{a}) \ = \ v(1 + \mathfrak{b}) \ = \ v + \mathfrak{b} \ = \ \Phi(1 + \mathfrak{a})$$

As Φ is invertible this implies $uv + \mathfrak{a} = 1 + \mathfrak{a}$ and hence $u + \mathfrak{a} = (v + \mathfrak{a})^{-1} \in (R/\mathfrak{a})^*$ is invertible. Now consider any $a \in R$, then $a \in \mathfrak{a}$ is equivalent to $a + \mathfrak{a} = 0 + \mathfrak{a}$. And as $u + \mathfrak{a}$ is a unit this is equivalent to $ua + \mathfrak{a} = 0 + \mathfrak{a}$. Now compute

$$0 + \mathfrak{b} \ = \ \Phi(0 + \mathfrak{a}) \ = \ \Phi(ua + \mathfrak{a}) \ = \ a\Phi(u + \mathfrak{a}) \ = \ a(1 + \mathfrak{b}) \ = \ a + \mathfrak{b}$$

That is $a + \mathfrak{a} = 0 + \mathfrak{a}$ is equivalent to $a + \mathfrak{b} = 0 + \mathfrak{b}$. Therefore $a \in \mathfrak{a}$ is equivalent to $a \in \mathfrak{b}$ and this is just the equality $\mathfrak{a} = \mathfrak{b}$ of subsets of R.

□

Proof of (3.95):

(i) It has already been shown in section 2.7 that $\mathbb{Z}$ is a PID. It only remains to verify, that $\mathbb{P}$ is infinite. Hence we suppose, that $\mathbb{P}$ is finite, say $\mathbb{P} = \{ p_1, \ldots, p_n \}$. Then we let $b := p_1 \cdot \cdots \cdot p_n + 1 \in \mathbb{Z}$ and choose an arbitrary prime divisor $p \geq 0$ of b, that is $b = ap$ for some $a \in \mathbb{Z}$. As $\mathbb{P}$ encompasses *all* (positive) prime elements of $\mathbb{Z}$ there is some $i \in 1 \ldots n$ with $p = p_i$. Without loss of generality we may take $p = p_1$. Now

$$p_1 \cdot \cdots \cdot p_n + 1 \;=\; b \;=\; ap \;=\; ap_1$$

Hence $1 = p_1(a - p_2 \cdot \cdots \cdot p_n)$ which means that p_1 is a unit of $\mathbb{Z}$ - an obvious contradiction to being a prime element. Hence $\mathbb{P}$ is not finite.

(ii) Suppose $\mathbb{Q} = \mathrm{Lh}(x_1, \ldots, x_n)$ was finitely generated, where $x_i = a_i/b_i$. Then we choose a prime number $p \in \mathbb{P}$ such that for any $i \in 1 \ldots n$ we have $p \not| \; b_i$. Such a prime exists, as by (i) there are infinitely many primes and all the b_i are only divisible by finitley many primes. Now suppose $1/p = k_1 x_1 + \cdots + k_n x_n$ for some $k_i \in \mathbb{Z}$. Let $b := b_1 \cdot \cdots \cdot b_n$ and $\widehat{b}_i := b/b_i \in \mathbb{Z}$, then

$$\frac{1}{p} \;=\; \sum_{i=1}^{n} k_i \frac{a_i}{b_i} \;=\; \frac{1}{b} \sum_{i=1}^{n} k_i a_i \widehat{b}_i \quad \Longrightarrow \quad b \;=\; p \sum_{i=1}^{n} k_i a_i \widehat{b}_i$$

In particular p would divide b and hence some of the b_i (as p is prime) in contradiction to the choice of p. Hence there can be no finite generating set of $\mathbb{Q}$ as an $\mathbb{Z}$-module.

It remains to show, that the set P truly generates $\mathbb{Q}$. To do this consider any $x = a/b \in \mathbb{Q}$ and write down a primary decomposition

$$b \;=\; s p_1^{k(1)} \cdot \cdots \cdot p_n^{k(n)}$$

where $s = 1$ or $s = -1$ and $p_i \in \mathbb{P}$. We will now use induction on the number n of distinct prime factors of b. If $n = 0$ then we readily have $x = a/s = as \in \mathbb{Z}$. And if $n = 1$ then

$$x \;=\; as \frac{1}{p_1^{k(1)}} \;\subseteq\; \mathbb{Z} \frac{1}{p_1^{k(1)}} \;\in\; \mathrm{Lh}(P)$$

For the induction step $n - 1 \to n$ let us abbreviate $q := p_1^{k(1)} \cdot \cdots \cdot p_{n-1}^{k(n-1)}$ and $p := p_n^{k(n)}$. Then $x = a/(sqp) = (as)/(qp)$. As p and q are relatively prime $\gcd(p, q) = \pm 1$ and $\mathbb{Z}$ is a PID there are some u and $v \in \mathbb{Z}$ such that $uq + vp = as$. Hence we find (note that $u/p \in \mathrm{Lh}(\mathbb{P})$ as in the case $n = 1$ and $v/q \in \mathrm{Lh}(\mathbb{P})$ by induction hypothesis)

$$x \;=\; \frac{as}{qp} \;=\; \frac{uq + vp}{qp} \;=\; \frac{u}{p} + \frac{v}{q} \;\in\; \mathrm{Lh}(\mathbb{P}) + \mathrm{Lh}(\mathbb{P}) \;=\; \mathrm{Lh}(\mathbb{P})$$

□

Proof of (3.49):

(i) First suppose M is simple and consider any $0 \neq x \in M$, then we need to show that $M = Rx$. But as $Rx \;\leq_{\mathsf{m}}\; M$ is a sub-module and M is simple we necessarily have $Rx = 0$ or $Rx = M$. But as also $0 \neq x \in Rx$ this only leaves $Rx = M$. For the converse direction we need to show that

M is simple, that is we pick up some sub-module $P \leq_{\mathfrak{m}} M$ and have to show $P = 0$ or $P = M$. If $P \neq 0$, then there is some $x \in P$ with $x \neq 0$. For this x we then get $M = Rx \subseteq P \subseteq M$ by assumption, such that truly $P = M$.

(ii) Here we have $M = Rm$, but in (3.22.(ii)) we have proved the following isomorphy of R-modules

$$\Phi \; : \; {}^{R}\Big/_{\mathsf{ann}(m)} \; \cong_{\mathfrak{m}} \; M \; : \; a + \mathsf{ann}(m) \mapsto am$$

Hence M is simple if and only if $R/\mathsf{ann}(m)$ is such. But by the correspondence theorem of sub-modules (3.16.(ii)) the sub-modules of $R/\mathsf{ann}(m)$ are of the form $P/\mathsf{ann}(m)$ for some sub-module $P \leq_{\mathfrak{m}} R$ with $\mathsf{ann}(m) \subseteq P$. That is: if $Q \leq_{\mathfrak{m}} M$ is a sub-module of M, then $\Phi^{-1}(Q) = P/\mathsf{ann}(m)$ for some $P \leq_{\mathfrak{m}} R$ and vice versa. Thereby $0 \leq_{\mathfrak{m}} M$ corresponds to $\mathsf{ann}(m) \leq_{\mathfrak{m}} R$ and $M \leq_{\mathfrak{m}} M$ corresponds to $R \leq_{\mathfrak{m}} R$. Any other sub-module (on either side) would spoil the simplicity and would correspond to some sub-module on the other side.

(v) Consider some module-homomorphism $\varphi : M \to N$. If $\varphi = 0$ then there is nothing ot prove, so let us consider $\varphi \neq 0$. As $\mathsf{kn}(\varphi) \leq_{\mathfrak{m}} M$ is a sub-module, but M is simple, we either have $\mathsf{kn}(\varphi) = 0$ or $\mathsf{kn}(\varphi) = M$. But $\varphi \neq 0$ rules out $\mathsf{kn}(\varphi) = M$ which leaves $\mathsf{kn}(\varphi) = 0$, which again is the injectivity of φ. Likewise, as $\mathsf{im}(\varphi) \leq_{\mathfrak{m}} N$ is a sub-module, but N is simple as well, we have $\mathsf{im}(\varphi) = 0$ or $\mathsf{im}(\varphi) = N$. Again $\varphi \neq 0$ rules out $\mathsf{im}(\varphi) = 0$ which leaves $\mathsf{im}(\varphi) = N$, which also is the surjectivity of φ.

(vi) By (v) we have $\mathsf{mend}(M) = \mathsf{maut}(M) \cup \{0\}$ as any non-zero endomorphism $\varphi : M \to M$ already is bijective. That is for any $\varphi \in \mathsf{mend}(M)$ there is some $\varphi^{-1} \in \mathsf{mend}(M)$ with $\varphi\varphi^{-1} = \mathbb{1}$ and $\varphi^{-1}\varphi = \mathbb{1}$. That is any φ is invertible. Hence the *ring* $\mathsf{mend}(M)$ (using the composition as multiplication) is a *division ring*.

(iii) As M is simple, then (i) implies $Rx = M = Ry$. Hence using the same reasoning as in (ii) we find two isomorphisms of R-modules

$$\Phi \; : \; {}^{R}\Big/_{\mathsf{ann}(x)} \; \cong_{\mathfrak{m}} \; M \; : \; a + \mathsf{ann}(x) \mapsto ax$$

$$\Psi \; : \; {}^{R}\Big/_{\mathsf{ann}(y)} \; \cong_{\mathfrak{m}} \; M \; : \; b + \mathsf{ann}(y) \mapsto by$$

Composing $\Psi^{-1}\Phi : R/\mathsf{ann}(x) \to R/\mathsf{ann}(y)$ we find an isomorphism of R-modules (defined by $a + \mathsf{ann}(x) \mapsto b + \mathsf{ann}(y)$ where $ax = by$). however by (3.83.(ii)) we know that this implies $\mathsf{ann}(x) = \mathsf{ann}(y)$ already. And the maximality of $\mathsf{ann}(y)$ has already been proved in (ii) (as in a commutative ring any sub-module already is an ideal).

(iv) If M is simple, then by (i) M alredy is of the form $M = Rx$ as $x \neq 0$. That is we find some $a \in R$ such that $y = ax$ since $y \in M = Rx$. As R is a commutative ring, we get an R-module-endomorphism by letting

$$\mu_a \; : \; M \to M \; : \; x \mapsto ax$$

As M is simple (vi) implies that we either have $\mu_a = 0$ or μ_a is bijective. But as $\mu_a(x) = ax = y \neq 0$ this rules out $\mu_a = 0$ such that μ_a truly is an an R-module-automorphism.

(vii) Fix some $0 \neq m \in M$, then as M is simple, we have $M = Rm$ according to (i). As $\varphi(m) \in M = Rm$ again, there is some $a \in R$ such that $\varphi(m) = am$. And for any $b \in R$ we then compute $\varphi(bm) = b\varphi(m) = b(am) = (ba)m = (ab)m = a(bm)$ as R is commutative. And as $M = Rm$ this means $\varphi(x) = ax$ for any $x \in M$. That is $\varphi = \mu_a : x \mapsto ax$ as has been claimed.

□

Proof of (3.51):

(i) Clearly, if xe and $ye \in Ae$ then $xe + ye = (x + y)e \in Ae$ and $(xe)(ye) = (xey)e \in Ae$ again (we even have $(xe)(ye) = x(ey)e = x(ye)e = xye^2 = xye$). Also for any $a \in R$ we have $a(xe) = (ax)e \in Ae$ such that Ae is an R-sub-semi-algebra of Ae. Also if $z \in A$ then $z(xe) = (zx)e \in Ae$ and $(xe)z = x(ez) = x(ze) = (xz)e \in Ae$ such that Ae also is an ideal of A. It remains to prove $1_{Ae} = e$ that is for any $xe \in Ae$ we need to show $e(xe) = xe$ and $(xe)e = xe$. The latter is due to $(xe)e = xe^2 = xe$ however and the first follows from $e(xe) = e(ex) = e^2x = ex = xe$, as well.

(ii) Clearly $0 \in \mathrm{cen}(A)$ as for any $g \in A$ we have $0g = 0 = g0$ and if $a \in R$, f, $f' \in \mathrm{cen}(A)$ then we get $(af)g = a(fg) = f(ag) = (ag)f = a(gf) = g(af)$ and $(f + f')g = fg + f'g = gf + gf' = g(f + f')$ such that af and $f + f' \in \mathrm{cen}(A)$ again. So far we have shown that $\mathrm{cen}(A) \leq_{\mathsf{m}} A$ is an R-sub-module of A. But also $(ff')g = f(f'g) = f(gf') = (fg)f' = (gf)f' = g(ff')$ implies $ff' \in \mathrm{cen}(A)$ as well. Altogether $\mathrm{cen}(A) \leq_{\mathsf{b}} A$ and if $1 \in A$ is the unit element then $1g = g = g1$ for any $g \in A$ such that $1 \in \mathrm{cen}(A)$ again. In particular, if u and $v \in \mathrm{cen}(A)$ then for any $g \in A$ we also get $g(uv) = (gu)v = (ug)v = u(gv) = u(vg) = (uv)g$ such that $uv \in \mathrm{cen}(A)$ again. So we also found that $\mathrm{cen}(A)$ is multiplicatively closed.

(iii) First of all we have $e(1 - e) = e - e^2 = e - e = 0$ and $(1 - e)e = e - e^2 = 0$ since e is idempotent, such that $e \perp (1 - e)$. Also we get $(1 - e)^2 = 1 - 2e + e^2 = 1 - 2e + e = 1 - e$ such that $1 - e$ is idempotent again. If $e \in \mathrm{cen}(A)$ also is central, then for any $x \in A$ we also get $x(1 - e) = x - xe = x - ex = (1 - e)x$ such that $1 - e \in \mathrm{cen}(A)$ is central, as well.

□

Proof of (3.52):

(i) Clearly for any $x \in A$ assumption (1) yields the equality $x = x1_A = x(\sum_i e_i) = \sum_i (xe_i) \subseteq \sum_i Ae_i$. And as x has been arbitrary this is $A = \sum_i Ae_i$. It remains to verify that for any $j \in 1 \ldots n$ we have

$$Ae_j \cap \left(\sum_{i \neq j} Ae_i \right) \;=\; 0$$

Thus consider any $x \in Ae_j$ that is $x = x_j e_j$ for some $x_j \in A$. Then we get $xe_j = x_j e_j e_j = x_j e_j = x$ by assumption (2). If now $x \in \sum_{i \neq j} Ae_i$ say $x = \sum_{i \neq j} x_i e_i$ then by assumption (3) we also get $x = xe_j = (\sum_{i \neq j} x_i e_i)e_j = \sum_{i \neq j} x_i e_i e_j = \sum_{i \neq j} x_i 0 = 0$. That is $x = 0$ as claimed.

(ii) The A-linearity of P_i is obvious: if x, $y \in A$ then $P_i(xy) = (xy)e_i = x(ye_i) = xP_i(y)$ and $P_i(x + y) = (x + y)e_i = xe_i + ye_i = P_i(x) + P_i(y)$. And the multiplicativity is due to the fact that e_i is a central idempotent: $P_i(xy) = (xy)e_i = (xy)e_i^2 = x(ye_i)e_i = x(e_i y)e_i = (xe_i)(ye_i) = P_i(x)P_i(y)$.

And finally we have $P_i(1) = e_i$ where $e_i \in Ae_i$ is the unit element of Ae_i, as $(xe_i)e_i = xe_i^2 = xe_i$ and $e_i(xe_i) = (e_ix)e_i = (xe_i)e_i = xe_i$. So altogether P_i truly is a homomorphism of A-algebras. The surjectivity of P_i is trivial, so it only remains to prove the equality for the kernel. Let $x = \sum_j x_j e_j$ then

$$P_i(x) \;=\; \sum_{j=1}^{n} P_i(x_j e_j) \;=\; \sum_{j=1}^{n} x_j e_j e_i \;=\; \sum_{j=1}^{n} x_j \delta_{i,j} e_j \;=\; x_i e_i$$

Hence we have $x \in \mathrm{kn}(P_i)$ if and only if $0 = P_i(x) = x_i e_i$ and considering that $x = \sum_j x_j e_j$ this is equivalent to $x = \sum_{j\neq i} x_j e_j$ that is to $x \in \sum_{j\neq i} Ae_j$. Note however that x_i itself need *not* be zero, it is the product $x_i e_i$ only, that has to be zero.

Let us denote $P := P_1 \oplus \cdots \oplus P_n : A \to A_1 \oplus \cdots \oplus A_n$ which is defined by $P(x) = (xe_1, \ldots, xe_n)$, that is P is the map of which we claim that it is an isomorphism of A-algebras. But as any P_i is a homomorphism of A-algebras it is clear, by construction, that P is an A-algebra-homomorphism again. And the bijectivity is due to (i), the inverse map is given by $(x_i) \mapsto x_1 + \cdots + x_n$.

(iii) Let us denote the basis of A by $\{ f_i \mid i \in I \}$. Then $1_A \in A$ has a basis representation concerning this basis

$$1_A \;=\; \sum_{i\in I} u_i f_i$$

where only finitely many of the $u_i \in R$ are non-zero. As also $f_i f_j \in A$ there are some $a_{i,j,k} \in R$ such that $f_i f_j$ has the basis representation

$$f_i f_j \;=\; \sum_{k\in I} a_{i,j,k} f_k$$

Combining these we find $f_j = 1_A f_j = (\sum_i u_i f_i) f_j = \sum_i u_i f_i f_j = \sum_i u_i \sum_k a_{i,j,k} f_k = \sum_k (\sum_i u_i a_{i,j,k}) f_k$. Comparing coefficients we find that for any $j, k \in I$ we get

$$\sum_{i\in I} u_i a_{i,j,k} \;=\; \delta_{j,k}$$

Now fix an arbitrary $r \in I$ and define $\kappa : A \to R$ by linear expansion of $f_i \mapsto a_{i,r,r}$ then for any $a \in R$ we can compute

$$\kappa(a1_A) = \kappa\left(a \sum_{i\in I} u_i f_i\right) = a \sum_{i\in I} u_i a_{i,r,r} = a \sum_{i\in I} u_i a_{i,r,r} = a$$

That is $\kappa\iota(a) = \kappa(a1_A) = a$ such that $\kappa\iota = \mathbb{1}_R$ and in particular ι is injective (and κ is surjective). Now let $A' := \mathrm{kn}(\kappa) \;\leq_{\mathfrak{m}}\; A$ and consider an arbitrary $x \in A$. Let $a := \kappa(x)$ and $x' := x - a1_A$ then $\kappa(x') = \kappa(x) - \kappa(a1_A) = a - a = 0$ such that $x' \in A'$. Thereby we have $x = a1_A + x'$ such that $A = R1_A + A'$. It remains to verify $(R1_A) \cap A' = 0$. Hence consider some $x \in (R1_A) \cap A'$ say $x = a1_A$. Then $0 = \kappa(x) = \kappa(a1_A) = a$ such that from $x = 0$ we get $A = R1_A \oplus A'$ as claimed.

□

Proof of (3.54):

(i) (a) $\implies$ (b): consider some idempotents $e, f \in A$ with $e \perp f$ (that is $ef = 0 = fe$) and $e + f = 1$.

Then all requirements of (3.52.(i)) are satisfied, such that we get the decoposition $A = Ae \oplus Af$ where the direct sum is that of A-modules. But by assumption A is indecomposable as an A-module such that $Ae = 0$ or $Af = 0$. But as $1 \in A$ this implies $e = 0$ or $f = 0$, as claimed.

(b) $\implies$ (c): it is clear that $0^2 = 0$ and $1^2 = 1$, conversely consider an idempotent $e \in A$ then we need to show $e = 0$ or $e = 1$. To do this let $f := 1 - e$, then $e + f = 1$ is clear and $e \perp f$ is due to (3.51.(iii)). So by assumption we get $e = 0$ or $f = 0$. The case $f = 0$ already is $e = 1$ however.

(c) $\implies$ (a): suppose $A = P \oplus Q$ is the direct sum of some A-sub-modules $P, Q \leq_{\mathsf{m}} A$. Then there are some $p \in P$ and $q \in Q$ such that $1 = p + q$. Now compute $p = p1 = p(p + q) = p^2 + pq$. As Q is an A-sub-module of A we have $pq \in Q$, but also $pq = p - p^2 \in P$ such that $pq \in P \cap Q = \{0\}$ which is $pq = 0$. This also proves $p^2 = p$ such that $p \in \mathrm{IP}(A)$ is an idempotent. But by assumption this means $p = 0$ or $p = 1$. In complete analogy we find $q = 0$ or $q = 1$. If we had $p = 1$ and $q = 1$ then $1 = p + q = 1 + 1$ such that $0 = 1$ in contradiction to $A \neq 0$. So we have $p = 0$ or $q = 0$. Now for any $x \in A$ we get $x = x1 = x(p + q) = xp + xq$ where $xp \in P$ as $p \in P$ and P is an A-sub-module of A. Likewise $xq \in Q$. Let us first regard the case $p = 0$: then for any $x \in A$ this would imply $x = xq \in Q$ such that $Q = A$. But as $A = P \oplus Q$ this means $P = 0$. In complete analogy $q = 0$ yields $Q = 0$ such that we have established the indecomposability of A.

(ii) (a) $\implies$ (d): let us consider some $e, f \in \mathrm{CIP}(A)$ such that $1 = e + f$, that is $ef = 0$ and $e + f = 1$. Then we take to the A-sub-semi-algebras $U := Ae$ and $U := Af$. Note that U and V thereby also are unital R-sub-semi-algebras of A according to (3.51.(i)). And clearly we have the following isomorphy of R-algebras

$$A \xrightarrow{\sim} U \oplus V \ : \ x \mapsto (xe, xf)$$

according to (3.52.(ii)). By assumption (a) this implies $U = 0$ or $V = 0$ such that $e = 0$ or $f = 0$, which is (d).

(c) $\iff$ (d): If $1 \in A$ is simple, then $A = A1$ trivially is a block. Conversely suppose we had $A = As$ for some simple element $s \in A$. Then there is some $r \in A$ such that $1 = rs$. And as s is central, this also is $sr = 1$ such that $s \in A^*$ is a unit element. Due to the isomorphy $A \xrightarrow{\sim} As : x \mapsto xs$ it is clear that $1 \in A$ has to be simple as well, as it corresponds to the simple element $s \in As = A$.

(d) $\implies$ (e): clearly $0, 1 \in A$ are central idempotents, so conversely let us assume we are given some $e \in \mathrm{CIP}(A)$. Then we need to show $e = 0$ or $e = 1$. But according to (3.51.(iii)) $f := 1 - e \in \mathrm{CIP}(A)$ is a central idempotent again, with $e \perp f$. Hence $1 = e \oplus f$ which implies $e = 0$ or $f = 0$, since 1 was assumed to be simple. But thereby $f = 0$ is just $e = 1$ again.

(e) $\implies$ (a): Suppose we had a decomposition $\Phi : A \xrightarrow{\sim} U \oplus V$ into some R-algebras U and V, that is Φ is an isomorphism of R-algebras. Let us denote the elements $e := \Phi^{-1}(1_U, 0_V) \in A$ and likewise $f := \Phi^{-1}(0_U, 1_V)$. Then it is clear that $e^2 = \Phi^{-1}(1_U^2, 0_V) = \Phi^{-1}(1_U, 0_V) = e$ and for any $x = \Phi^{-1}(u, v)$ we get

$$\begin{aligned} xe &= \Phi^{-1}(u,v)\Phi^{-1}(1_U,0_V) = \Phi^{-1}(u,0_V) \\ &= \Phi^{-1}(1_U,0_V)\Phi^{-1}(u,v) = ex \end{aligned}$$

Hence we get $e \in \mathrm{CIP}(A)$ which by assumption is $e = 0$ or $e = 1$. In case $e = 0 = \Phi^{-1}(0_U, 0_V)$ we

have $1_P = 0_P$ such that $P = 0$ and in case $e = 1\Phi^{-1}(1_U, 1_V)$ we have $0_Q = 1_Q$ such that $Q = 0$. Altogether A is indecomposable, as claimed.

By now we have established the equivalence of (a) $\iff$ (c) $\iff$ (d) $\iff$ (e). Let us abbreviate $C := \mathrm{cen}(A) \leq_{\mathrm{a}} A$, then we will now prove (a) $\implies$ (b): if A is indecomposable, then by (e) we have $\mathrm{cip}(A) = \{0, 1\}$. In particular this means $\mathrm{cip}(C) = \{0, 1\}$ such that C satisfies (e) as well. And we already know that this implies (b). Conversely for (b) $\implies$ (a): if C is indecomposable, then by (d) $1 \in C$ is simple. That is there is no non-trivial decomposition $1 = e \oplus f$ with e, $f \in \mathrm{cen}(C) = C = \mathrm{cen}(A)$. Hence $1 \in A$ is simple as an element of A, as well. But this is (d) for A, such that A is indecomposable, itself.

□

Proof of (3.96):
Suppose X is a generating set of M with $|X| = \mathrm{rank}(M)$. As $\varphi : M \twoheadrightarrow N$ is surjective, for any $y \in N$ there is some $x \in M$ such that $y = \varphi(x)$. Also as X generates M we can choose some $a_i \in R$ and $x_i \in X$ such that $x = a_1x_1 + \cdots + a_nx_n$. And clearly this yields

$$y \;=\; \varphi(x) \;=\; \sum_{i=1}^{n} a_i\varphi(x_i) \;\in\; \mathrm{Lh}\Big(\varphi(X)\Big)$$

As $y \in N$ has been chosen arbitarily we have just seen, that $N = \mathrm{Lh}(\varphi(X))$. And from this we find the first inequality

$$\mathrm{rank}(N) \;\leq\; |\varphi(X)| \;\leq\; |X| \;=\; \mathrm{rank}(M)$$

For the second inequality choose some generating sets $X \subseteq P$ of P and $V \subseteq M/P$ of M/P such that $\mathrm{rank}(P) = |X|$ and $\mathrm{rank}(M/P) = |V|$. By construction of M/P any $v \in V$ is of the form $u + P$ for some $u \in M$. Thus for any $v \in V$ we may pick up some $u \in M$ such that $v = u + P$. We now take those u to build up a set $U \subseteq M$, that is we have $V = \{\, u + P \mid u \in U \,\}$ and $|U| = |V|$. We will now show, that $X \cup U$ generates M. To do this consider any $x \in M$: as $x + P \in M/P = \mathrm{Lh}(V)$ there are some $a_i \in R$ and $u_i \in U$ such that

$$x + P \;=\; \sum_{i=1}^{m} a_i(u_i + P) \;=\; \left(\sum_{i=1}^{n} a_iu_i\right) + P$$

That is $x - (a_1u_1 + \cdots + a_mu_m) \in P$. From this again we find some $b_j \in R$ and $p_j \in X$ such that $x - (a_1u_1 + \cdots + a_mu_m) = b_1p_1 + \cdots + b_np_n$ since X generates P. Altogether this yields

$$x \;=\; \sum_{i=1}^{m} a_iu_i + \sum_{j=1}^{n} b_jp_j \;\in\; \mathrm{Lh}(U \cup X)$$

Again, as $x \in M$ has been chosen arbitarily, this proves $M = \mathrm{Lh}(X \cup U)$, that is $X \cup U$ generates M and from this we get

$$\mathrm{rank}(M) \leq |P \cup U| \leq |P| + |U| = |P| + |V| = \mathrm{rank}(P) + \mathrm{rank}\left(M \Big/ P\right)$$

□

Proof of (3.99):

(i) If $n = 0$ then $X := \{ x_1, \ldots, x_n \}$ degenerates to $X = \emptyset$ and as X generates M this implies $M = 0$. Thus the only choice of an element $y_1 \in M$ is $y_1 = 0$ and this obviously is R-linear dependent. Thus we may assume $1 \leq n$. As M is the R-linear hull of X, we can choose some $a_{i,j} \in R$ (where $i \in 1 \ldots n$ and $j \in 1 \ldots n+1$) such that

$$y_j \;=\; \sum_{i=1}^{n} a_{i,j}\, x_i$$

Using these elements we first define the $\mathbb{Z}$-subalgebra S of R generated by the $a_{i,j}$. That is, we let

$$S \;:=\; \mathbb{Z}\left[a_{i,j} \mid i \in 1 \ldots n,\, j \in 1 \ldots n+1\right]$$

Note that $\mathbb{Z}$ is a noetherian ring (even a PID, by (2.71)) and S is a finitely generated $\mathbb{Z}$-algebra (by construction). Hence by the Hilbert basis theorem (2.42) S is a noetherian ring again. We now take to the S-module generated by the x_i

$$M_S \;:=\; \mathsf{Lh}_S \{ x_1, \ldots, x_n \}$$

Now, as M_S is a finitely generated S-module and S is a noetherian ring, M_S is a noetherian S-module, according to (3.111.(vi)). And clearly

$$y_j \;=\; \sum_{i=1}^{n} a_{i,j}\, x_i \;\in\; M_S$$

We will now recursively define the elements $y_j[m] \in M_S$ for any index $j \in 1 \ldots n+1$ and any $m \in \mathbb{N}$. We start by taking $y_j[0] := y_j$, then we continue

$$y_j[m+1] \;:=\; \sum_{i=1}^{n} a_{i,j}\, y_i[m]$$

To streamline our notation let us abbreviate $z_m := y_{n+1}[m]$. Now suppose that $Y := \{ y_1, \ldots, y_n, y_{n+1} \}$ was R-linearly independent. As $S \leq_{\mathsf{r}} R$ is a sub-ring of R, then in particular Y would be S-linearly independent. In an intermediate claim we will prove, that in this case the elements

$$y_1[m],\, \ldots,\, y_n[m],\, z_m = y_{n+1}[m],\, z_0,\, \ldots,\, z_{m-1}$$

are S-linearly independent for any $m \in \mathbb{N}$. The case $m = 0$ is trivial, as $y_j[0] = y_j$ our assumption on the y_j grants their S-linear independence. Let us use induction on m, then for the induction step we have to regard an S-linear relation of the form

$$\sum_{j=1}^{n+1} a_j\, y_j[m+1] + \sum_{l=0}^{m} b_l\, z_l \;=\; 0$$

Let us insert the recursive definition for the $y_j^{(m+1)}$ into this relation, then we find a relation of the

form

$$\begin{aligned} 0 &= \sum_{j=1}^{n+1} a_j y_j[m+] + \sum_{l=0}^{m} b_l z_l \\ &= \sum_{j=1}^{n+1} a_j \sum_{i=1}^{n} a_{i,j} y_i[m] + \sum_{l=0}^{m} b_l z_l \\ &= \sum_{i=1}^{n} \left(\sum_{j=1}^{n+1} a_j a_{i,j} \right) y_i[m] + \sum_{l=0}^{m-1} b_l z_l + b_m y_{n+1}[m] \end{aligned}$$

By the induction hypothesis these elements are S-linearly independent, such that we find $b_l = 0$ for any $l \in 1 \dots m$ and for any $i \in 1 \dots n$ also

$$\sum_{j=1}^{n+1} a_j a_{i,j} = 0$$

But this allows to give a linear relation between the y_j, just use the definition of the $a_{i,j}$ and compute (in the same manner as before)

$$\sum_{j=1}^{n+1} a_j y_j = \sum_{i=1}^{n} \left(\sum_{j=1}^{n+1} a_j a_{i,j} \right) x_i = 0$$

But by assumption the y_j are S-linearly independent, such that we necessarily have $a_j = 0$ for any $j \in 1 \dots n+1$ as well. Altogether we have proved the intermediate claim of linear independance. In particular the elements z_0, z_1, z_2 and so on are S-linearly independent. Thus - if we define

$$M_m := \mathrm{Lh}_S \{ z_l \mid l \in 0 \dots m \}$$

We get an ascending chain $M_0 \subseteq M_1 \subseteq M_2 \subseteq \dots$ of S-sub-modules of M_S. Yet this chain is strictly increasing: suppose we had $z_{m+1} \in M_m$ for some $m \in \mathbb{N}$ then there would be some $s_0, \dots, s_m \in S$ such that

$$z_{m+1} = \sum_{l=0}^{m} s_l z_l$$

which contradicts the S-linear independence of the z_l and hence we have $M_0 \subset M_1 \subset M_2 \subset \dots$. But a strictly increasing chain within the *noetherian* module M_S is impossible. The only way to solve this contradiction is to drop the assumption of R-linear independence of the y_j. That is Y is R-linear dependent, as we had claimed.

(ii) As $\{ m_1, \dots, m_n \}$ is a basis of M we obtain a well-defined endomorphism of R-modules, by letting

$$\varphi : M \to M : \sum_{i=1}^{n} a_i m_i \mapsto \sum_{i=1}^{n} a_i x_i$$

As $\{ x_1, \dots, x_n \}$ generates M this endomorphism is surjective. But then we can apply (3.82.(i)) to find that φ also is injective. That is if $\sum_i a_i x_i = 0$ then $\sum_i a_i m_i = 0$. But as the m_i are linearly independent this means $a_i = 0$ for any $i \in 1 \dots n$. And this is the linear independence of the x_i again.

(iii) Since the basis B by definition generates M as an R-module and the rank of M is the *minimal* cardinality of a generating set, trivially

$$\mathrm{rank}(M) \;\leq\; |B|$$

It remains to prove the equality. Let us choose some generating set $G \subseteq M$ of minimal cardinality, that is $|G| = \mathrm{rank}(M)$.

In a first step we assume that $n := |G| \in \mathbb{N}$ is finite. Suppose we had $n < |B|$, then we could choose some $\{ b_1, \ldots, b_n, b_{n+1} \} \subseteq B$. But as G generates M this would mean, that $\{ b_1, \ldots, b_n, b_{n+1} \}$ is R-linearly dependent, according to (i). But this contradicts the R-linear independence of B and hence we have

$$\mathrm{rank}(M) \;=\; |G| \;=\; n \;=\; |B|$$

In the second step, we suppose that $|G|$ is infinite. Then necessarily B is infinite as well - else we would have $|B| < |G| = \mathrm{rank}(M)$. As G generates M, for any $b \in B \subseteq M$, we can choose a *finite* subset $F_b \subseteq G$ such that $b \in \langle F_b \rangle_{\mathfrak{m}}$. Now define

$$F \;:=\; \bigcup_{b \in B} F_b \;\subseteq\; G$$

Then as B generates M and any $b \in B$ is generated by $F_b \subseteq F$ it is clear, that F also is a generating set of the entire module M:

$$\langle F \rangle_{\mathfrak{m}} \;=\; \sum_{b \in B} \langle F_b \rangle_{\mathfrak{m}} \;\supseteq\; \sum_{b \in B} Rb \;=\; \mathrm{Lh}_R(B) \;=\; M$$

Since any F_b has been finite, but B is infinite the cardinality of F is precisely the cardinality of B. But as $F \subseteq G$ this already yields the converse inequality

$$|B| \;=\; |F| \;\leq\; |G|$$

(iv) Choose some generating set $X \subseteq M$ of M with $|X| = \mathrm{rank}(M)$. Further, as F is free, we can choose some basis $B \subseteq F$ of F. Let us first suppose X is a finite set, say $X = \{ x_1, \ldots, x_n \}$. The basis $B \subseteq M$ is an R-linearly independent set, and hence B cannot contain more than n elements, as we have seen in (i). Hence by (ii) we have

$$\mathrm{rank}(F) \;=\; |B| \;\leq\; n \;=\; |X| \;=\; \mathrm{rank}(M)$$

So let us now consider the case that X is infinite - this will require some slight tricks of cardinal arithmetic: As X generates $M = \mathrm{Lh}(X)$ for any $y \in B$ there is a finite set $\omega(y) \subseteq X$ such that $y \in \mathrm{Lh}(\omega(y))$. Hence there is a map from B to the set $\Omega(X) := \{ Z \subseteq X \mid \#Z < \infty \}$ of finite subsets of X, given by

$$\omega \;:\; B \to \Omega(X) \;:\; y \mapsto \omega(y)$$

But as X is infinite we have $|X| = |\Omega(X)|$. Now consider any finite subset $Z \in \Omega(X)$, say $Z = \{ z_1, \ldots, z_n \} \subseteq X$. Then the fiber of Z is given to be $\omega^{-1}(Z) = \{ y \in B \mid \omega(y) = Z \}$. Thereby $\omega(y) = Z$ yields $y \in \mathrm{Lh}(\omega(y)) = \mathrm{Lh}(Z)$. Note that since $\omega^{-1}(Z) \subseteq B$ is contained in

the basis B of F it is R-linearly independent. And as $\mathrm{Lh}(Z)$ is generated by at most n elements (i) implies, that $\omega^{-1}(Z)$ cannot contain more that n elements: $\#\omega^{-1}(Z) \leq \#Z$. Thus any fiber of ω is finite. This now means, that the cardinality of B cannot exceed the cardinality of $\Omega(X)$. And altogether that is

$$\mathrm{rank}(F) \;=\; |B| \;\leq\; |\Omega(X)| \;=\; |X| \;=\; \mathrm{rank}(M)$$

□

Proof of (3.97):
If $\Phi : M \;\cong_{\mathsf{m}}\; N$ is an isomorphism of R-modules, then in particular $\Phi : M \twoheadrightarrow N$ is an epimorphism. Hence by (3.96) we find that $\mathrm{rank}(N) \leq \mathrm{rank}(M)$. But as the inverse $\Phi^{-1} : N \twoheadrightarrow M$ is surjective as well, we also have $\mathrm{rank}(M) \leq \mathrm{rank}(N)$. Altogether we have found

$$\mathrm{rank}(M) \;=\; \mathrm{rank}(N)$$

Conversely suppose that $\mathrm{rank}(M) = \mathrm{rank}(N)$. As both M and N are free we may choose bases $A \subseteq M$ of M and $B \subseteq N$ of N. As R is commutative and non-zero we may invoke (3.99.(iii)) to see

$$|A| \;=\; \mathrm{rank}(M) \;=\; \mathrm{rank}(N) \;=\; |B|$$

That is there is some bijection $\sigma : A \longleftrightarrow B \subseteq N$. As A is a basis of M we may now expand this map linearly. That is we use (3.72.(ii)) to define an R-module homomorphism

$$\Phi : M \to N : \sum_{x\in A} a_x x \mapsto \sum_{x\in A} a_x \sigma(x) \;=\; \sum_{y\in B} a_{\sigma^{-1}(y)} y$$

Likewise, as B is a basis as well, we can linearly expand $\sigma^{-1} : B \longleftrightarrow A \subseteq M$, as well. Then it is immediately clear, that $\Phi\Psi = \mathbb{1}_M$ and $\Psi\Phi = \mathbb{1}_N$. That is $\Phi : M \to N$ is an isomorphism with inverse $\Phi^{-1} = \Psi$. In particular we have $\Phi : M \;\cong_{\mathsf{m}}\; N$ as we had claimed. □

Proof of (3.102):

(i) Of course the proof will be an application of the lemma of Zorn. So let us regard the collection of all R-lineary independent subsets $L' \subseteq M$ containing L, formally that is

$$\mathcal{L} \;:=\; \left\{\, L' \subseteq M \mid L' \text{ is } R\text{-lineary independent}, L \subseteq L' \,\right\}$$

It is clear that $L \in \mathcal{L}$ and hence $\mathcal{L} \neq \emptyset$ is non-empty. Also $\mathcal{L}$ is partially ordered under the inclusion $\subseteq$. Now consider some chain $(L_i) \subseteq \mathcal{L}$ (where $i \in I$) in $\mathcal{L}$ and let

$$L' \;:=\; \bigcup_{i\in I} L_i \;\subseteq\; M$$

In order to establish $L' \in \mathcal{L}$ we have to show that L' is R-linearly independent again. Thus consider any $x_k \in L'$ and any $a_k \in R$ (where $k \in 1 \ldots n$) such that

$$a_1 x_1 + \cdots + a_n x_n \;=\; 0$$

By construction of L' for any $i \in 1 \ldots k$ there is some $i(k) \in I$ such that $x_k \in L_{i(k)}$. Since the L_i

form a chain we can assume (by renumbering the x_k), that

$$L_{i(1)} \subseteq L_{i(2)} \subseteq \ldots \subseteq L_{i(n)}$$

In particular $x_k \in L_{i(n)}$ for any $k \in 1 \ldots n$. But as $L_{i(n)}$ is linearly independent (it is contained in $\mathcal{L}$) the above equality implies $a_1 = \cdots = a_n = 0$. Hence L' is linearly independent, as well, such that $L' \in \mathcal{L}$. Hence every chain in $\mathcal{L}$ has an upper bound so that we may invoke the lemma of Zorn, to find a maximal element of $\mathcal{L}$.

(ii) If $x \in L$, then $x \in \mathrm{Lh}(L)$ is clear, such that we may take $a = 1$. Also if there is some $a \neq 0$ with $ax = 0$, then there is nothing to prove. So from now on we assume $x \notin L$ and $ax = 0 \implies a = 0$ for any $a \in R$. Then, as L is a maximal linear indepenedent set, $L \cup \{ x \}$ is no longer linear independent. That is there are some $y_1, \ldots, y_n \in L$ and some $a, b_1, \ldots, b_n \in R$ that are not identically zero, such that

$$ax + b_1 y_1 + \cdots + b_n y_n = 0$$

Thereby $ax = 0$ cannot be, as else $\{ y_1, \ldots, y_n \} \subseteq L$ would be linearly dependent. And by assumption this already implies $a \neq 0$. Now we see, that $ax = -(b_1 y_1 + \cdots + b_n y_n) \in \mathrm{Lh}(L)$ holds true as well.

(iii) By definition $\mathrm{free}(M) = 0$ means that $\emptyset \subseteq M$ is a maximal linearly independent set. This happens iff for any $x \in M$ the set $\{ x \} \subseteq M$ is linearly dependent already. The latter means that there is some $0 \neq a \in R$ such that $ax = 0$. And this again is precisely the property of M being a torsion module.

(iv) If L is a linearly independent set of M, then clearly $F := \mathrm{Lh}(L)$ is generated by L (by construction) and L is linearly independent (by assumption). That is L is a basis of F and F is free. If now $R \neq 0$ is a non-zero commutative ring, then lemma (3.99.(iv)) yields

$$|L| = \mathrm{rank}(F) \leq \mathrm{rank}(M)$$

(v) If $n = 0$ then $M = F$ and hence M is free with basis L itself. In particular L is a maximal linear independent subset of M and there is nothing to prove. Now suppose $n \geq 1$ the assumption that $L \cup \{ x_i \}$ is linearly dependent means that there are some $a_i \in R$ and $a_{i,u} \in R$ such that

$$a_i x_i + \sum_{u \in L} a_{i,u} u = 0$$

Note that this sum is finite only, since only finitely many $a_{i,u}$ are non-zero. Thereby $a_i \neq 0$ as else L would have been linearly dependent already. For later use define

$$a := \prod_{i=1}^{n} a_i \neq 0$$

Thereby $a \neq 0$ since all the $a_i \neq o$ and R is assumed to be an integral domain. Also note that $a/a_i \in R$ is a well-defined element of R. We will now prove that M/F is a torsion module: To see

this consider any $y \in M$ then, since $M = F + \mathrm{Lh}\{ x_1, \ldots, x_n \}$, we may write y in the form

$$y \;=\; f + \sum_{i=1}^{n} b_i x_i$$

for some $f \in F$ and $b_i \in R$. Then we will show $ay \in F$ using a staightforward computation

$$\begin{aligned} ay &= af + \sum_{i=1}^{n} a b_i x_i \\ &= af + \sum_{i=1}^{n} b_i \frac{a}{a_i} a_i x_i \\ &= af - \sum_{i=1}^{n} b_i \frac{a}{a_i} \sum_{u \in L} a_{i,u} u \\ &= af - \sum_{u \in L} \left(\sum_{i=1}^{n} b_i \frac{a}{a_i} a_{i,u} \right) u \end{aligned}$$

As the $u \in L$ generate F we see that truly $ay \in F$. But from this we find, that L is a maximal linearly independent set. Consider any $L' \subseteq M$ with $L \subseteq L'$. If there was some $y \in L' \setminus L$ then we have some $a \in R$ with $a \neq 0$ and $ay \in F = \mathrm{Lh}(L)$. Hence $L \cup \{ y \}$ and therefore L' are linearly dependent. And in particular we have the equalities

$$\mathrm{free}(M) \;=\; |L| \;=\; \dim(F)$$

If also follows that M/F is a torsion module: Consider any $y + F \in M/F$ then $a(y+F) = ay + F = 0 + F = 0 \in M/F$. And this is all that has been claimed.

(vi) We first prove that M/F where $F = \mathrm{Lh}(L)$ is a torsion module. Hence we consider any $z = x + F \in M/F$. As L is maximal linear independent (iii) yields some $a \in R$ with $a \neq 0$ such that $ax \in F$. Hence

$$az \;=\; ax + F \;=\; 0 + F \;=\; 0 \;\in\; M \Big/ F$$

And if $F \;\leq_{\mathrm{m}}\; M$ is a free sub-module of M with basis B, then $B \subseteq M$ clearly is linearly independent. It remains to prove the maximality of B. Thus suppose $B \subseteq X$. If there is some $x \in X$ with $x \notin B$, then (as M/F is a torsion module) we can choose some $a \in R$ with $a \neq 0$ such that $a(x + F) = 0 + F$. As above that is $ax \in F = \mathrm{Lh}(L)$. That is there are some $b_1, \ldots, b_n \in R$ and $y_1, \ldots, y_n \in B$ such that

$$ax \;=\; b_1 y_1 + \cdots + b_n y_n$$

Thus $b_1 y_1 + \cdots + b_n y_n - ax = 0$ is a linear relation with $a \neq 0$ within the set X. That is X is not linearly independent and hence $B \subseteq M$ is maximally linear independent.

(vii) We will first prove that $|L| = |L'|$. To do this we regard the map $\alpha : L \to L' : x \mapsto a_x x$. By definition of L' it is clear that α is surjective. Thus it remains to show the injectivity: suppose there were some $x, y \in L$ such that $x \neq y$ and $a_x x = a_y y$. Then

$$a_x x - a_y y \;=\; 0$$

As $\{ x, y \} \subseteq L$ is linear independent, this would imply $a_x = a_y = 0$ in contradiction to the choice of a_x and a_y. Hence α also is injective, that is we have established the bijecton $\alpha : L \longleftrightarrow L'$.

It remains to prove the linear independence of L'. Suppose we are given some $x(k) \in L'$ and $b(k) \in R$ (where $k \in 1 \dots n$) such that

$$0 \;=\; b(1)a(1)x(1) + \cdots + b(n)a(n)x(n)$$

Hereby we denoted $a(k) := a_{x(k)} \in R$. As $\{ x(1), \dots, x(n) \} \subseteq L$ is linear independent this implies $b(k)a(k) = 0$ for any $k \in 1 \dots n$. But as R is an integral domain and $a(k) \neq 0$ this already is $b(k) = 0$ for any $k \in 1 \dots n$. That is L' also is linearly independent.

(viii) As L is a maximal linear independent set, we have seen in (ii) that for any $x \in K$ there is some $a_x \in R$ with $a_x \neq 0$ and $a_x x \in Q := \mathrm{Lh}(L)$. Let us now denote $K' := \{ a_x x \mid x \in K \}$ and $P := \mathrm{Lh}(K')$. By (iv) we know, that K' is linearly independent again and hence P is a free submodule of M with basis K'. In fact, as $K' \subseteq Q$ we even have $P \subseteq Q$. Now by (3.99.(iii)) again we find

$$|K| \;=\; |K'| \;=\; \mathrm{rank}(P) \;\leq\; \mathrm{rank}(Q) \;=\; |L|$$

Reversing the roles of K and L in the above argument we also see that $|L| \leq |K|$ and hence $|K| = |L|$.

(ix) According to (i) we may pick up maximal linear independent sets $K \subseteq P$ and $\{ y + P \mid y \in L \} \subseteq M/P$ for some sufficient $L \subseteq M$. First of all it is clear, that $K \cap L = \emptyset$, because if we had $x \in K \cap L$ then $x \in K \subseteq P$ and hence $x + P = 0 + P$ such that $\{ x + P \}$ would be linearly dependent in contrast to $x \in L$. Hence we have $|K \cup L| = |K| + |L|$. It remains to prove that $K \cup L$ is a maximal linear independent set in M, as we then have

$$\mathrm{free}(M) \;=\; |K \cup L| \;=\; |K| + |L| \;=\; \mathrm{free}(P) + \mathrm{free}\left(M \Big/ P \right)$$

For the linear independence of $K \cup L$ suppose we have some $x_i \in K$ (where $i \in 1 \dots m$) and $y_j \in L$ (where $j \in 1 \dots n$) such that

$$z \;:=\; a_1 x_1 + \cdots + a_m x_m + b_1 y_1 + \cdots + b_n y_n \;=\; 0$$

for some a_i and $b_j \in R$. As $x_i \in K \subseteq P$ we then find that $0 + P = z + P = \sum_j b_j y_j + P = \sum_j b_j (y_j + P)$. But as $y_j \in L$ we know that the $y_j + P$ are linearly independent and hence necessarily $b_1 = \cdots = b_n = 0$. That is $0 = z = \sum_i a_i x_i$, but as the x_i are linearly independent as well, this implies $a_1 = \cdots = a_m = 0$ once more. Hence there only are trivial linear relations in $K \cup L$, that is $K \cup L$ is linearly independent.

It remains to prove the maximality of $K \cup L$. Hence suppose we are given any $z \in M$ with $z \notin K \cup L$. As $z + P \in M/P$ and $\{ y + P \mid y \in L \}$ is a maximal linear independent set (ii) implies that there is some $c \in R$ with $c \neq 0$ such that $cz + P \in \mathrm{Lh}(y + P \mid y \in L)$. That is there are some $y_j \in L$ and $b_j \in R$ (where $j \in 1 \dots n$ again) such that $cz + P = \sum_j b_j (y_j + P) = \sum_j b_j y_j + P$. That is $cz - \sum_j b_j y_j \in P$. And as $K \subseteq M$ is a maximal linear set as well (ii) once more implies that there

is some $d \in R$ with $d \neq 0$ such that $d(cz - \sum_j b_j y_j) \in \mathrm{Lh}(K)$. Altogether that is

$$d\left(cz - \sum_{j=1}^{n} b_j y_j\right) \;=\; \sum_{i=1}^{m} a_i x_i$$

for some $x_i \in K$ and $a_i \in R$ (where $i \in 1 \ldots m$ again). Rearranging this we found $dcz - (\sum_i a_i x_i + \sum_j db_j y_j) = 0$. Thereby $dc \neq 0$, as $c \neq 0$ and $d \neq 0$ and R is an integral domain. That is we have found a non-trivial linear relation in $K \cup L \cup \{ z \}$ which means that this set is linearly dependent. So at last $K \cup L$ is maximal linear independent.

(x) Let $L = \{ m_i \mid i \in I \} \subseteq M$ be a maximal linearly independent set in M and define $F := \mathrm{Lh}(L)$ again. Then F is a free R-module having the basis L. Now by (3.160.(i)) $\{ 1 \otimes m_i \mid i \in I \} \subseteq E \otimes M$ is an E-basis of $E \otimes M$ and hence

$$\dim_E(E \otimes M) \;=\; \dim_R(F) \;=\; |L| \;=\; \mathrm{free}(M)$$

□

Proof of (3.104):
The proof of theorem (i) is elementary, but not the easiest one. We have tried to increase its readability by presenting each step separately. It also makes use of the *well-ordering theorem* - a classical result from set-theory. there also is a direct proof of the theorem presented in [Adkins, Weintraub, 3.6.2]. However this proof is rather lengthy and intricate, such that we prefer this version:

(1) First of all, let $\{ m_i \mid i \in I \}$ be a basis of M. We now choose a well-ordering $\leq$ on I. Then for any $j \in I$ we denote the following sub-modules of M:

$$\begin{aligned} M_j &:= \mathrm{Lh}(m_i \mid i \leq j) \\ L_j &:= \mathrm{Lh}(m_i \mid i < j) \end{aligned}$$

It is clear that $i \leq j$ there by imples $M_i \subseteq M_j$ due to the transitivity of $\leq$. In fact we also get $M_j = L_j \oplus Rm_j$ but we do not require this fact. Instead let us denote further sub-modules of P:

$$\begin{aligned} P_j &:= M_j \cap P \\ K_j &:= L_j \cap P \end{aligned}$$

Again it is clear that $i \leq j$ now implies $P_i \subseteq P_j$ as this inherited from the M_j. But in this case we only have $K_j \subseteq P_j \subseteq P$ and it may well be, that $K_j = P_j$. In the following we will analyze the difference (i.e. quotient) between L_j and K_j. To do this we finally need to denote the coefficient map

$$\pi_j \;:\; M \to R \;:\; \sum_{i \in I} a_i m_i \;\mapsto\; a_j$$

The restriction of π_j to P_j will be denoted by φ_j. That is φ_j is to be the following R-module-homomorphism

$$\pi_j \;:\; P_j \to R \;:\; \sum_{i \in I} a_i m_i \;\mapsto\; a_j$$

(2) Clearly the kernel of π_j is the linear hull of $\{ m_i \mid i \neq j \}$. And if this is intersected with M_j there only remains L_j. In consequence the kernel of φ_j is nothing but K_j:

$$\mathrm{kn}(\varphi_j) \;=\; \mathrm{kn}(\pi_j) \cap P_j \;=\; \mathrm{kn}(\pi_j) \cap M_j \cap P \;=\; L_j \cap P \;=\; K_j$$

And as $im(\varphi_j) \;\leq_{\mathrm{m}}\; R$ is an R-sub-module, it even is an ideal in R (since R is commutative). But as R even is a PID, there has to be some $a_j \in R$ such that $im(\varphi_j) = a_j R$. In particular (if $a_j \neq 0$) we have the following isomorphy of R-modules

$$R \;\xrightarrow{\sim}\; \mathrm{im}(\varphi_j) \;:\; \lambda \mapsto a_j \lambda$$

(it is injective, since R is an integral domain and surjective by construction). But as $\mathrm{kn}(\varphi_j) = K_j$ and $im(\varphi_j) = a_j R$ the first isomorphism theorem (3.78.(ii)) have the following isomorphy of

$$P_j \Big/ K_j \;\xrightarrow{\sim}\; a_j R \;\;:\;\; x + K_j \mapsto \pi_j(x)$$

Note that clearly $K_j = L_j$ is equivalent to $a_j = 0$. Also note that in case $a_j \neq 0$ the inverse of the isomorphism $\lambda \mapsto a_j \lambda$ is given by $b \mapsto b/a_j$. Thus combining these two isomorphies we find the following isomorphy of R-modules

$$\Phi_j \;:\; P_j \Big/ K_j \;\xrightarrow{\sim}\; R \;:\; x + K_j \mapsto \frac{\pi_j(x)}{a_j}$$

That is to say that for any $x \in P_j$ we have established the equality $\pi_j(x) = a_j \Phi_j(x + k_j)$. Or more intuively speaking Φ_j yields the j-th coefficient of x once we scratch the a_j.

(3) For any $j \in J$ with $a_j \neq 0$ let us now choose some $p_j \in P_j$ such that $\Phi_j(p_j + K_j) = 1$. That is $\pi_j(p_j) = a_j$ - or intuitively speaking again: p_j is an element of P_j that hast a_j as its j-th coefficient. For formalities sake let us denote:

$$H \;:=\; \{ i \in I \mid a_i \neq 0 \}$$

We now claim that $\{ p_i \mid i \in H \}$ is an R-linearly independent set. That is we have to consider finitely many incides $i(1), i(2), \ldots, i(n) \in H$ with

$$\sum_{k=1}^{n} \lambda_{i(k)} p_{i(k)} \;=\; 0$$

for some coefficients $\lambda_{i(k)} \in R$. Scratching all the zero coefficients we may assume $\lambda_{i(k)} \neq 0$ for any $k \in 1 \ldots n$. By renumbering we may also assume $i(1) < i(2) < \cdots < i(n)$, as $\leq$ is a total order. But in consequence this yields the ascending chain of sub-modules of P, namely $P_{i(1)} \subseteq P_{i(2)} \subseteq \ldots \subseteq P_{i(n)}$. That is if $j := i(n)$ is the maximal index then we have $p_{i(k)} \in P_{i(k)} \subseteq P_j$ for any $k \in 1 \ldots n$. But then we get

$$0 \;=\; \varphi_j(0) \;=\; \sum_{k=1}^{n} \lambda_{i(k)} \varphi_j(p_{i(k)}) \;=\; \sum_{k=1}^{n} \lambda_{i(k)} a_j \delta_{i(k),j} \;=\; \lambda_j a_j$$

as $\varphi_j(p_{i(k)}) = \pi_j(p_{i(k)}) = a_j\delta_{i(k),j}$. But since $a_j \neq 0$ and R is an integral domain this means $\lambda_j = 0$ - a contradiction. Hence we must have scratched all coefficients $\lambda_{i(k)}$ which means there is no such sum. Altogether the linear independence of $\{\, p_i \mid i \in H \,\}$ is established.

(4) It remains to prove that $\{\, p_i \mid i \in H \,\}$ also generates P as an R-module (then it is a basis of P and we have $\mathrm{rank}(P) = |H| \leq |I| = \mathrm{rank}(M)$). To do this let us abbreviate

$$P_0 \;:=\; \mathrm{Lh}_R\{\, p_i \mid i \in H \,\} \;\subseteq\; P$$

As $\{\, m_i \mid i \in I \,\}$ is an R-basis of M for any $x \in M$ there are uniquely determined coefficients $\lambda_i \in R$ such that

$$x \;=\; \sum_{i\in I} \lambda_i m_i$$

Thereby the set $\{\, i \in I \mid \lambda_i \neq 0 \,\}$ has been finite. And as $\leq$ is a total order this enables us to introduce the maximal index $\mu(x)$ enumerating a non-zero coefficient of x, that is:

$$\mu(x) \;:=\; \max\{\, i \in I \mid \lambda_i \neq 0 \,\} \;\in\; I$$

We have to show $P_0 = P$ of course, so assume we had the contrary $P \setminus P_0 \neq \emptyset$. Then - as I even is well-ordered - there would be a minimal among these maximal indexes

$$\alpha \;:=\; \min\{\, \mu(x) \mid x \in P \setminus P_0 \,\} \;\in\; I$$

Recall that being minimal means that for any $x \in P \setminus P_0$ we have that $\mu(x) \leq \alpha$ implies $\mu(x) = \alpha$. Now consider any $x \in K_\alpha = L_\alpha \cap P$. Since $x \in L_\alpha$ we have $\mu(x) < \alpha$. And due to the minimality of α this implies $x \notin P \setminus P_0$. But as also $x \in P$ this only leaves $x \in P_0$ such that we have argued, that

$$K_\alpha \;\subseteq\; P_0$$

Now let us further pick up some element $u \in P \setminus P_0$ such that $\mu(u) = \alpha$ and let us denote its basis decomposition by

$$u \;=\; \sum_{k=1}^{n} \nu_{i(k)} m_{i(k)}$$

for some $\nu_{i(k)} \in R$ with $\nu_{i(k)} \neq 0$. Renumbering we may again assume, that $i(1) < i(2) < \cdots < i(n) = \alpha$. As $u \in M_\alpha$ and also $u \in P$ we have $u \in M_\alpha \cap P = P_\alpha$. And therefore we may regard $\nu_\alpha = \varphi_\alpha(u) \in a_\alpha R$. That is there is some $b \in R$ such that $\nu_\alpha = a_\alpha b$. By construction of the isomorphism Φ_α this means

$$\Phi_\alpha(u + K_\alpha) \;=\; b$$

As $\nu_\alpha \neq 0$ we also find $a_\alpha \neq 0$ and hence $bp_\alpha \in P_0$ by definition of P_0. Then we may compute

$$\Phi_\alpha(u - bp_\alpha + K_\alpha) = \Phi_\alpha(u + K_\alpha) - b\Phi_\alpha(p_\alpha + K_\alpha) = b - b \cdot 1 = 0$$

This means $u - bp_\alpha + K_\alpha = 0 + K_\alpha$ or in other words $u - bp_\alpha \in K_\alpha \subseteq P_0$. This again means $u + P_0 = bp_\alpha + P_0 = 0 + P_0$ such that $u \in P_0$ - a contradiction. Hence $P \setminus P_0$ must have been empty which is $P_0 = P$. That is $\{\, p_i \mid i \in H \,\}$ truly generates P as an R-module and hence is a

basis of P.

The proof of theorem (ii) is rather short in comparison: Let $\{ m_i \mid i \in I \}$ be a generating set of M where $|I| = \mathrm{rank}(M)$. We have the epimorphism

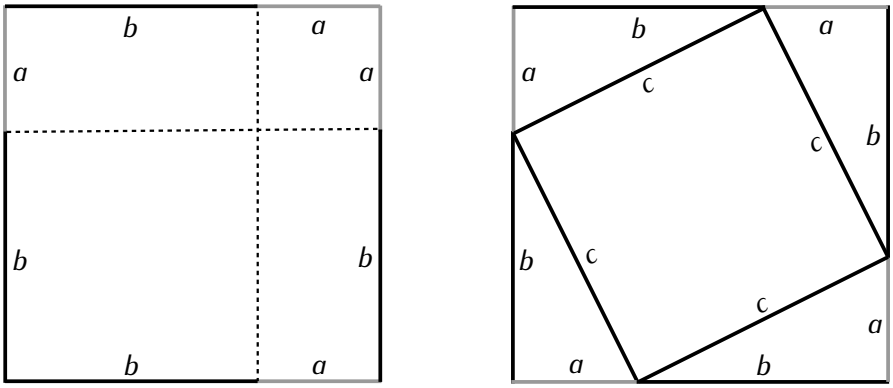
$$\mu \ : \ R^{\oplus I} \ \twoheadrightarrow \ M \ : \ (a_i) \mapsto \sum_{i \in I} a_i m_i$$

Let $P_0 := \mu^{-1}(P) \ \leq_{\mathsf{m}} \ R^{\oplus I}$. As $R^{\oplus I}$ is a free module [it has the Euclidean basis] over the PID R we know by (i) that P_0 is free as well and more importantly: $\dim(P_0) \leq \dim(R^{\oplus I}) = |I| = \mathrm{rank}(M)$. But as μ is surjective, we also have $\mu(P_0) = \mu\big(\mu^{-1}(P)\big) = P$ such that the restriction of μ to P_0 is an epimorphism onto P:

$$\mu \ : \ P_0 \ \twoheadrightarrow \ P \ : \ (a_i) \mapsto \sum_{i \in I} a_i m_i$$

In particular by (3.96) we have $\mathrm{rank}(P) \leq \mathrm{rank}(P_0) = \dim(P_0) \leq \mathrm{rank}(M)$. And if M is is finitely generated, then P is finitely generated as well, since $\mathrm{rank}(P) \leq \mathrm{rank}(M) < \infty$.
Next we prove (iii): If M is free, then it already is torsion-free, according to (3.23.(ii)), since R is an integral domain (even a PID). Conversely if M is torsion-free, then by (3.23.(iv)) - as M also is finitely generated - it is embedded $M \ \xrightarrow{\sim} \ N \ \leq_{\mathsf{m}} \ R^n$ into the free R-module R^n. But by (i) the sub-module N is free again, such that M has to be free, as well, due to the isomorphy to N.
Finally it remains to prove (iv): Generally - for any module, over any ring - we have the following short exact sequence of R-modules

$$0 \to \mathrm{TOR}(M) \ \xrightarrow{\subseteq} \ M \ \xrightarrow{\varrho} \ M \Big/ \mathrm{TOR}(M) \to 0$$



Since M is finitely generated so is $Q := M/\mathrm{TOR}(M)$. But as Q also is torsion-free, according to (3.23.(i)), (iii) tells us, that Q is free. But then (3.90) yields the desired isomorphy

$$M \quad \cong_{\mathsf{m}} \quad M \Big/ \mathrm{TOR}(M) \oplus \mathrm{TOR}(M)$$

□

15.5 Proofs of Chapter 4

Proof of (4.112):
Let us look at a square, whose length of its sides is $a+b$ in two separate ways: First we can decompose that square into a square of size a, a square of size b and two rectangles of size ab. On the other hand we can decompose said square into a square of size c and 4 triangles that fit the description of the lemma:

As it is the same square its area is equal, namely $(a+b)^2$. Every two triangles in the figure on the right side can be combined to a rectangle of area ab. Thus their area is $ab/2$. The decomposition of the square of size $a+b$ now yield two separate formulas for the area of the square

$$\begin{aligned}(a+b)^2 &= a^2+b^2+2\cdot ab\\ (a+b)^2 &= c^2+4\cdot\frac{ab}{2} \;=\; c^2+2\cdot ab\end{aligned}$$

Note that the first equality is just the binomial formula for $(a+b)^2$. As these two are equal we may subtract $2ab$ from the terms to find the desired pythagorean equality $c^2=(a+b)^2-2ab=a^2+b^2$. □

Proof of (4.8):

(i) It is clear that $\mathrm{mat}_{m,n}(R)$ is an R-module, as a matrix in nothing but a peculiar way of arranging an mn-tuple $A\in R^{mn}$. If this doesn't convince you try the following reasoning: $M:=R^m$ is a R-module under the point-wise operations. Hence $\mathrm{mat}_{m,n}(R)=M^n$ is an R-module under the point-wise operations, too. But the point-wise operations are precisely what we have taken for the addition and scalar-multiplication of matrices. And the fact that $\mathcal{E}$ is an R-basis follows immediately from (3.61.(vi)) once we notice, that any matrix $A=(a_{i,j})$ can be written uniquely, as

$$A \;=\; \sum_{i=1}^{m}\sum_{j=1}^{n} a_{i,j}\,E_{i,j}$$

(ii) We will first prove the associativity of the matrix multiplication. To do this fix any index $i\in 1\ldots m$ and $l\in 1\ldots q$ and compute

$$\mathrm{ent}_{i,l}((AB)C) \;=\; \sum_{k=1}^{p}\mathrm{ent}_{i,k}(AB)\,\mathrm{ent}_{k,l}(C)$$

$$\begin{aligned} &= \sum_{k=1}^{p}\sum_{j=1}^{n} \mathsf{ent}_{i,j}(A)\,\mathsf{ent}_{j,k}(B)\,\mathsf{ent}_{k,l}(C) \\ &= \sum_{j=1}^{n} \mathsf{ent}_{i,j}(A) \sum_{k=1}^{p} \mathsf{ent}_{j,k}(B)\,\mathsf{ent}_{k,l}(C) \\ &= \sum_{j=1}^{n} \mathsf{ent}_{i,j}(A)\,\mathsf{ent}_{j,l}(BC) \\ &= \mathsf{ent}_{i,l}(A(BC)) \end{aligned}$$

The distributivity can be proved by a direct computation as well. In this case we prefer to e4mploy the scalar product however:

$$\begin{aligned} \mathsf{ent}_{i,k}(A(B+C)) &= \langle \mathsf{row}_i(A), \mathsf{col}_k(B+C)\rangle \\ &= \langle \mathsf{row}_i(A), \mathsf{col}_k(B) + \mathsf{col}_k(C)\rangle \\ &= \langle \mathsf{row}_i(A), \mathsf{col}_k(B)\rangle + \langle \mathsf{row}_i(A), \mathsf{col}_k(C)\rangle \\ &= \mathsf{ent}_{i,k}(AB) + \mathsf{ent}_{i,k}(AC) \\ &= \mathsf{ent}_{i,k}(AB + AC) \\ \mathsf{ent}_{i,k}((A+B)C)) &= \langle \mathsf{row}_i(A+B), \mathsf{col}_k(C)\rangle \\ &= \langle \mathsf{row}_i(A) + \mathsf{row}_i(B), \mathsf{col}_k(C)\rangle \\ &= \langle \mathsf{row}_i(A), \mathsf{col}_k(C)\rangle + \langle \mathsf{row}_i(B), \mathsf{col}_k(C)\rangle \\ &= \mathsf{ent}_{i,k}(AC) + \mathsf{ent}_{i,k}(BC) \\ &= \mathsf{ent}_{i,k}(AC + AC) \end{aligned}$$

(iii) As mat_n is an R-module by (i) and the multiplication is associative and distributive by (ii) we already know that $\mathsf{mat}_n(R)$ is an R-semi-algebra. It remains to prove that $\mathbb{1}$ truly is a unit element in $\mathsf{mat}_n(R)$. To see this consider any $A \in \mathsf{mat}_n(R)$ and compute

$$\begin{aligned} \mathsf{ent}_{i,k}(\mathbb{1}\,A) &= \sum_{j=1}^{n} \mathsf{ent}_{i,j}(\mathbb{1})\,\mathsf{ent}_{j,k}(A) \\ &= \sum_{j=1}^{n} \delta_{i,j}\,\mathsf{ent}_{j,k}(A) \;=\; \mathsf{ent}_{i,k}(A) \\ \mathsf{ent}_{i,k}(A\,\mathbb{1}) &= \sum_{j=1}^{n} \mathsf{ent}_{i,j}(A)\,\mathsf{ent}_{j,k}(\mathbb{1}) \\ &= \sum_{j=1}^{n} \mathsf{ent}_{i,j}(A)\,\delta_{j,k} \;=\; \mathsf{ent}_{i,k}(A) \end{aligned}$$

(iv) The inverse generally is uniquely determined in associative grupoids, let us repeat the proof here: Suppose both B and $B' \in \mathsf{mat}_n(R)$ satisfy $AB = \mathbb{1}_n = BA$ and $AB' = \mathbb{1}_n = B'A$ respectively. Then we find $B = B'$ by a easy computation

$$B \;=\; B\mathbb{1}_n \;=\; B(AB') \;=\; (BA)B' \;=\; \mathbb{1}_n B' \;=\; B'$$

(v) We will first prove $\mathrm{cen}(R)\mathbb{1} \subseteq \mathrm{cen}(\mathrm{mat}_n(R))$, that is we consider any $a \in \mathrm{cen}(R)$ and $B = (b_{i,j}) \in \mathrm{mat}_n(R)$. Then we have to check that $(a\mathbb{1})B = B(a\mathbb{1})$. But as a commutes with all other elements of R this is quite easy to see:

$$(a\mathbb{1})B \;=\; a(\mathbb{1}B) \;=\; aB \;=\; (ab_{i,j}) \;=\; (b_{i,j}a) \;=\; B(a\mathbb{1})$$

Conversely consider any $A = (a_{i,j}) \in \mathrm{cen}(\mathrm{mat}_n(R))$, that is A is a matrix, that commutes with all other matrices. In particular we have $AE_{r,s} = E_{r,s}A$ for any $r, s \in 1 \ldots n$. Now evaluate the (i,k)th entry

$$\begin{aligned}
\mathrm{ent}_{i,k}(A\,E_{r,s}) &= \sum_{j=1}^{n} a_{i,j}\,\delta_{j,r}\,\delta_{k,s} \;=\; a_{i,r}\,\delta_{k,s} \\
\mathrm{ent}_{i,k}(E_{r,s}\,A) &= \sum_{j=1}^{n} \delta_{i,r}\,\delta_{j,s}\,a_{j,k} \;=\; \delta_{i,r}\,a_{s,k}
\end{aligned}$$

That is for any i, k, r and $s \in 1 \ldots n$ we have $a_{i,r}\delta_{k,s} = \delta_{i,r}a_{s,k}$. Let us choose $s := k$ then this equality specializes to

$$a_{i,r} \;=\; \delta_{i,r}\,a_{k,k}$$

In particular - by taking $r := i$ - we find $a_{i,i} = a_{k,k}$ for any indexes i, k. And if $r \neq i$, then we have $a_{i,r} = 0$. That is A is a diagonal matrix, in which all diagonal elements are equal. In short: A is of the form $A = a\mathbb{1}$ for some $a \in R$. Now take $B := b\mathbb{1}$, then clearly $AB = ab\mathbb{1}$ and $BA = ba\mathbb{1}$. But as $AB = BA$ and $b \in R$ is arbitrary, this implies $a \in \mathrm{cen}(R)$. Hence we also have $\mathrm{cen}(\mathrm{mat}_n(R)) \subseteq \mathrm{cen}(R)\mathbb{1}$.

(vi) Let $A = (a_{i,j})$ and $B = (b_{i,j})$ where $i, j \in 1 \ldots n$. Then by definition of the matrix-multiplication we have

$$\mathrm{ent}_{i,i}(AB) \;=\; \sum_{j=1}^{n} a_{i,j}b_{j,i}$$

Thus we find the equality of $\mathrm{tr}(AB)$ and $\mathrm{tr}(BA)$ using the following computation in which we rename the indices i and j [in the third step], use the commutativity of R [in the fourth step] and swap the summation symbols [in the fith step]

$$\begin{aligned}
\mathrm{tr}(AB) &= \sum_{i=1}^{n} \mathrm{ent}_{i,i}(AB) \;=\; \sum_{i=1}^{n}\sum_{j=1}^{n} a_{i,j}b_{j,i} \\
&= \sum_{j=1}^{n}\sum_{i=1}^{n} a_{j,i}b_{i,j} \;=\; \sum_{j=1}^{n}\sum_{i=1}^{n} b_{i,j}a_{j,i} \\
&= \sum_{i=1}^{n}\sum_{j=1}^{n} b_{i,j}a_{j,i} \;=\; \sum_{i=1}^{n} \mathrm{ent}_{i,i}(BA) \\
&= \mathrm{tr}(BA)
\end{aligned}$$

(vii) Let us first check, that $\varphi_A : R^n \to R^m$ truly is R-linear. Again this is a straightforward computation using the definition of the matrix-vector multiplication. Pick up $x, y \in R^n$ and $a \in R$, then for any

$i \in 1 \ldots m$

$$\begin{aligned}
[A(x+y)]_i &= \sum_{j=1}^{n} a_{i,j} [x+y]_j = \sum_{j=1}^{n} a_{i,j}(x_j + y_j) \\
&= \sum_{j=1}^{n} a_{i,j} x_j + \sum_{j=1}^{n} a_{i,j} y_j = [Ax]_i + [Ay]_i \\
[A(ax)]_i &= \sum_{j=1}^{n} a_{i,j} [ax]_j = \sum_{j=1}^{n} a_{i,j} a x_j \\
&= a \sum_{j=1}^{n} a_{i,j} x_j = a\,[Ax]_i
\end{aligned}$$

The latter, since R is commutative. As this is true for any $i \in 1 \ldots n$ and the operations in R^m are point-wise again, we have $A(x+y) = Ax + Ay$ and $A(ax) = a\,Ax$. Therefore $\varphi_A : x \mapsto Ax$ truly is in $\mathrm{mhom}(R^n, R^n)$ such that $A \mapsto \varphi_A$ is well-defined. Next we have to check, that this map a homomorphism of R-modules, that is $\varphi_{A+B} = \varphi_A + \varphi_B$ and $\varphi_{aA} = a\varphi_A$. But this has already been dealt with, in (ii):

$$\begin{aligned}
\varphi_{A+B}(x) &= (A+B)x = Ax + Bx = \varphi_A(x) + \varphi_B(x) \\
\varphi_{aA}(x) &= (aA)x = a(Ax) = a\varphi_A(x)
\end{aligned}$$

It remains to check the bijectivity of $A \mapsto \varphi_A$. We will do this by presenting the inverse map: If $\varphi : R^n \to R^m$ is R-linear, then take

$$[\varphi] := (a_{i,j}) \quad \text{where} \quad a_{i,j} := \big[\varphi(e_j)\big]_i$$

where $e_1 = (1, 0, \ldots, 0)$ to $e_n = (0, \ldots, 0, 1)$ denote the Euclidean basis vectors of R^n. Thus if $A = [\varphi]$ we have to check that $\varphi_A = \varphi$ and $[\varphi_A] = A$. The latter is straightforward:

$$\mathrm{ent}_{i,j}([\varphi_A]) = \big[\varphi_A(e_j)\big]_i = \big[Ae_j\big]_i = \big[\mathrm{col}_j(A)\big]_i = \mathrm{ent}_{i,j}(A)$$

And since this is true for any $i \in 1 \ldots m$ and any $j \in 1 \ldots n$ we have $[\varphi_A] = A$. If now $A = [\varphi]$ then $a_{i,j} = [\varphi(e_j)]_i$ and hence $\mathrm{col}_j(A) = (a_{1,j}, \ldots, a_{m,j}) = \varphi(e_j) \in R^m$. Therefore

$$\varphi_A(e_j) = Ae_j = \mathrm{col}_j(A) = \varphi(e_j)$$

Thus we have $\varphi_A(e_j) = \varphi(e_j)$ for any $j \in 1 \ldots n$ and as these for a basis of R^n and both φ_A and φ are R-linear we have $\varphi_A(x) = \varphi(x)$ for any $x \in R^n$. That is $\varphi_A = \varphi$ such that $\varphi \mapsto [\varphi]$ truly is the inverse map of $A \mapsto \varphi_A$. In particular $A \mapsto \varphi_A$ is bijective and hence an isomorphism of R-modules.

(viii) It is clear, that the transposition $A \mapsto A^*$ is bijective - the inverse map is the transposition $\mathrm{mat}_{n,m}(R) \to \mathrm{mat}_{m,n}(R) : B \mapsto B^*$ again. And the R-linearity of the transposition is straightforward again

$$\mathrm{ent}_{j,i}((aA+B)^*) = \mathrm{ent}_{i,j}(aA+B) = a\,\mathrm{ent}_{i,j}(A) + \mathrm{ent}_{i,j}(B)$$

$$= \quad a\,\mathrm{ent}_{j,i}(A^*) + \mathrm{ent}_{j,i}(B^*) \;=\; \mathrm{ent}_{j,i}(aA^* + B^*)$$

(ix) Recall that R is assumed to be commutative here. Let us compare all the entries of the matrices $(AB)^*$ and B^*A^*, $i \in 1\ldots l$ and $k \in 1\ldots n$. Then by definition of the matrix-multiplication we find that all entries are equal, just compute

$$\begin{aligned}\mathrm{ent}_{k,i}(B^*A^*) &= \langle \mathrm{row}_k(B^*), \mathrm{col}_i(A^*)\rangle \;=\; \langle \mathrm{col}_k(B), \mathrm{row}_i(A)\rangle \\ &= \langle \mathrm{row}_i(A), \mathrm{col}_k(B)\rangle \;=\; \mathrm{ent}_{i,k}(AB) \\ &= \mathrm{ent}_{k,i}((AB)^*)\end{aligned}$$

(x) Let us first assume that A is invertible, then an easy computation yields $\mathbb{1}_n = \mathbb{1}_n^* = (AA^{-1})^* = (A^{-1})^*A^*$ where the latter equality is due to (vi). Likewise $\mathbb{1}_n = (A^{-1}A)^* = A^*(A^{-1})^*$. Hence we have seen that in this case A^* is invertible, too and that the inverse is given to be $(A^{-1})^*$. That is we have proved the equality

$$(A^*)^{-1} \;=\; \left(A^{-1}\right)^*$$

If conversely A^* is invertible, then we have just seen that $(A^*)^* = A$ is invertible. So this already establishes the equivalence of the invertibilities of A and A^*.

(xi) Let us denote $x = (x_1,\ldots,x_n) \in R^n$ and $y = (y_1,\ldots,y_m) \in R^m$, then it is straightforward to compute

$$\begin{aligned}\langle Ax, y\rangle &= \sum_{i=1}^{m} [Ax]_i\, y_i \;=\; \sum_{i=1}^{m}\sum_{j=1}^{n} \mathrm{ent}_{i,j}(A)\, x_j\, y_i \\ &= \sum_{j=1}^{n} x_j \sum_{i=1}^{m} \mathrm{ent}_{i,j}(A)\, y_i \;=\; \sum_{j=1}^{n} x_j \sum_{i=1}^{m} \mathrm{ent}_{j,i}(A^*)\, y_i \\ &= \sum_{j=1}^{n} x_j\, [A^*y]_j \;=\; \langle x, A^*y\rangle\end{aligned}$$

□

Proof of (4.10):
If $u \in 1\ldots l = l(1) + \cdots + l(r)$ is any row-number of A, then there are some $i \in 1\ldots r$ and $u' \in 1\ldots l(i)$ such that the u-th row of A runs across the u'-th rows of $A^{i,1}$ to $A^{i,s}$. That is we can pick up $i \in 1\ldots r$ and $u' \in 1\ldots l(i)$ such that $u = u' + l(1) + \cdots + l(i-1)$. Likewise for a column-number $v \in 1\ldots n = n(1) + \cdots + n(t)$ of B, there are some $k \in 1\ldots t$ and $v' \in 1\ldots n(j)$ such that the v-th column of B runs across the v'-th columns of $B^{1,j}$ to $B^{s,j}$. Again we pick up $k \in 1\ldots t$ and $v' \in 1\ldots n(n)$ such that $v = v' + n(1) + \cdots + n(k-1)$.

Then the (u,v)-th entry of AB is given to be $\langle \mathrm{row}_u(A), \mathrm{col}_v(B)\rangle$. But as the u-th row of A and the v-th row of are concatenations of the u'-th rows of the $A^{i,j}$ and of the v'-th columns of the $B^{j,k}$ respectively

we find that

$$\mathsf{ent}_{u,v}(AB) \;=\; \langle \mathsf{row}_u(A), \mathsf{col}_v(B)\rangle \;=\; \langle \begin{pmatrix} \mathsf{row}_{u'}(A^{i,1}) \\ \vdots \\ \mathsf{row}_{u'}(A^{i,s}) \end{pmatrix}, \begin{pmatrix} \mathsf{col}_{v'}(B^{1,k}) \\ \vdots \\ \mathsf{col}_{v'}(B^{s,k}) \end{pmatrix} \rangle$$

By assumption on the compatible block-structure of A and B these rows and columns are of compatible sizes, too and hence we may conclude

$$\mathsf{ent}_{u,v}(AB) \;=\; \sum_{j=1}^{s} \langle \mathsf{row}_{u'}(A^{i,j}), \mathsf{col}_{v'}(B^{j,k})\rangle \;=\; \sum_{j=1}^{s} \mathsf{ent}_{u',v'}(A^{i,j}B^{j,k}) \;=\; \mathsf{ent}_{u',v'}\left(\sum_{j=1}^{s} A^{i,j}B^{j,k}\right)$$

If we now chunk up AB into the resulting block structure [i.e. we have r rows of the sizes $l(1)$ to $l(r)$ and t columns of the sizes $n(1)$ to $n(t)$] then the (u',v')-index of the sub-matrices corresponds to the (u,v)-index of the whole matrix and hence the proof is complete. □

Proof of (4.20):
Let us denote $X = (x_1, x_2, \ldots x_m) \in \mathsf{mat}_{p,m}(R)$ and $Y := (y_1, y_2, \ldots, y_n) \in \mathsf{mat}_{p,n}(R)$. Then by definition of the matrix multiplication, the (i,k)-th entry of XA is given to be

$$[XA]_{i,k} \;=\; \sum_{j=1}^{m} x_{i,j}a_{j,k}$$

Thereby $x_{i,j} = [x_j]_i$ is just the i-th component of $x_j \in R^p$. And as R was assumed to be commuttive this enables us to rewrite

$$[XA]_{i,k} \;=\; \sum_{j=1}^{m} a_{j,k}\left[x_j\right]_i \;=\; \left[\sum_{j=1}^{m} a_{j,k}x_j\right]_i$$

But by assumption this is just $[y_k]_i$. Thus we find that the k-th column of XA is just y_k and this is precisely the claim of this proposition. □

Proof of (4.14):
The definiton of $\mathsf{gl}_n(R)$ is precisely that of the multiplicative group of $\mathsf{mat}_n(R)$, hence there is nothing to prove.

It is clear that the unit element $\mathbb{1}_n$ of $\mathsf{mat}_n(R)$ is contained in $\mathsf{tri}_n(R)$. Also if A and $B \in \mathsf{tri}_n(R)$ are any two upper triangular matrices, then for any $a \in R$ and any $i, j \in 1 \ldots n$ we have

$$\mathsf{ent}_{i,j}(aA + B) \;=\; a\,\mathsf{ent}_{i,j}(A) + \mathsf{ent}_{i,j}(B)$$

In particular if $j < i$ we see that $\mathsf{ent}_{i,j}(aA + B) = 0$, such that $aA + B$ is an upper triangular matrix again. By taking $a = 1$ we see that $A + B \in \mathsf{tri}_n(R)$ and by taking $a = -1$ and $B = 0$ we also have $-A \in \mathsf{tri}_n(A)$. That is we have proved, that $(\mathsf{tri}_n(R), +)$ is a subgroup of $(\mathsf{mat}_n(R), +)$ - in fact we have shown that $\mathsf{tri}_n(R)$ is an R-sub-module of $\mathsf{mat}_n(R)$.

It remains to prove that $\mathsf{tri}_n(R)$ is closed under multiplication of matrices as well. Hence consider any two upper triangular matrices $A = (a_{i,j})$ and $B = (b_{i,j}) \in \mathsf{tri}_n(R)$ again. Then for any $i, k \in 1 \ldots n$ we

have

$$\mathrm{ent}_{i,k}(AB) \;=\; \sum_{j=1}^{n} a_{i,j}\, b_{j,k}$$

But since $A \in \mathrm{tri}_n(R)$ we have $a_{i,j} = 0$ for any $j < i$. And as $B \in \mathrm{tri}_n(B)$ as well, we also have $b_{j,k} = 0$ of any $j > k$. Hence the only summands which might be non-zero are those from $j = k$ to $j = i$. That is the sum breaks down to

$$\mathrm{ent}_{i,k}(AB) \;=\; \sum_{j=k}^{i} a_{i,j}\, b_{j,k}$$

Hence if $i < k$ there are no non-zero elements left at all and the sum is 0. But this precisely means that $AB \in \mathrm{tri}_n(R)$ is an upper triangular matrix again, and this had to be shown.

In the next step, let us prove the recursion formula for solving the SLE $Tx = b$. As $t_{i,j} = 0$ for any $i > j$ it is clear, that $Tx = b$ breaks down to the following equations (for any $i \in 1 \ldots n$)

$$\sum_{j=i}^{n} t_{i,j} x_j \;=\; b_i$$

In particular for $i = n$ we have $t_{n,n} x_n = b_n$. If now $t_{n,n} \in R^*$ is invertible, then we get $x_n = t_{n,n}^{-1} b_n$. Now suppose we have already computed x_n, x_{n-1} and so on, up to x_{i+1}. Then the i-th equation yields

$$t_{i,i} x_i + \sum_{j=i+1}^{n} t_{i,j} x_j \;=\; b_i$$

Thus if $t_{i,i} \in R^*$ is invertible, as well, we find precisely the recursion formula for x_i given in the claim

$$x_i \;=\; t_{i,i}^{-1} \left(b_i - \sum_{j=i+1}^{n} t_{i,j} x_j \right)$$

In particular: If any $t_{i,i} \in R^*$ then T is invertible. Let us now prove, that T^{-1} is an upper triangular matrix again. By (4.11) the j-th column of T^{-1} is x_j where $Tx_j = e_j$. That is we have to prove, that $[x_j]_i = \mathrm{ent}_{i,j}(T^{-1}) = 0$ whenever $i > j$. We do this recursively starting with $j = n$ and working our way down to $j = 1$. For $j = n$ the condition $i > j$ is void, the last column is irrelevant. Now consider $j < n$ and start with $i = n$, then $[x_j]_n = t_{n,n}^{-1} [e_j]_n = 0$. Suppose we have already proved $[x_j]_i = 0$ for $i = n$ down to $i = k + 1$, where $k > j$. Then we use the recursion formula again, to find

$$[x_j]_k \;=\; t_{k,k}^{-1} \left([e_j]_k - \sum_{l=k+1}^{n} t_{k,l} [x_j]_l \right)$$

As both $[e_j]_k = 0$ and $[x_j]_l = 0$ for $l \geq k + 1$, by assumption, we find $[x_j]_k = 0$ too. This changes, at $k = j$, as here $[e_j]_j = 1$ such that $[x_j]_j = t_{j,j}^{-1}$. Therefore we have proved two things: (1) T^{-1} is an upper triangular matrix again and (2) if T is invertible, then any $t_{j,j} \in R$ is an invertible element, too. □

Proof of (4.15):

We need to show, that $\mathrm{tri}_n^1(R)$ is a subgroup of $\mathrm{gl}_n(R)$. As $\mathbb{1}_n \in \mathrm{tri}_n^1(R)$ is trivial, we commence by proving, that $\mathrm{tri}_n^1(R)$ is closed under the multiplication of matrices. That is we start with $A = (a_{i,j})$ and $B = (b_{i,j}) \in \mathrm{tri}_n^1(R)$ and need to show $AB \in \mathrm{tri}_n^1(R)$. We have just seen in the proof of (4.14) that the

(i,k)-th entry of AB is given by the following sum

$$\mathrm{ent}_{i,k}(AB) \;=\; \sum_{j=k}^{i} a_{i,j}b_{j,k}$$

and that thereby $AB \in \mathrm{tri}_n(R)$. It remains to verify, that AB only has 1 on its diagonal. But for $i = k$ this formula already turns into

$$\mathrm{ent}_{i,i}(AB) \;=\; a_{i,i}b_{i,i} \;=\; 1$$

Thus $AB \in \mathrm{tri}_n^1(R)$, as claimed. It remains to prove that A^{-1} is an element of $\mathrm{tri}_n^1(R)$ again. But we have already argued in (4.14) that $A^{-1} \in \mathrm{tri}_n(A)$. Again it remains to verify $\mathrm{ent}_{j,j}(A^{-1}) = 1$ for any $j \in 1 \ldots n$. As in the proof of (4.14) let x_j denote the j-th column of A^{-1} which amounts to $Ax_j = e_j$. In the case $j = n$ we have $[x_n]_n = a_{n,n}^{-1}[e_n]_n = 1$. For $j < n$ we start with $[x_j]_n = a_{n,n}^{-1}[e_j]_n = 0$. Then for any k with $j < k \leq n$ we use the recursion formula of (4.14) to prove that $[x_j]_k = 0$:

$$[x_j]_k \;=\; a_{k,k}^{-1}\left([e_j]_k - \sum_{l=k+1}^{n} a_{i,l}\cdot[x_j]_l\right) \quad 1\cdot(0-0) \;=\; 0$$

For $k = j$ however we get $[e_j]_j = 1$ and hence the same recursion formula yields 1 as $[x_j]_j = 1$ which is the (j,j)-th entry of A^{-1}. From this we get $A^{-1} \in \mathrm{tri}_n^1(R)$, as needed.

$$[x_j]_j \;=\; a_{j,j}^{-1}\left([e_j]_j - \sum_{l=j+1}^{n} a_{i,l}\cdot[x_j]_l\right) \quad 1\cdot(1-0) \;=\; 1$$

Altogether $\mathrm{tri}_n^1(R)$ is a subgroup of the multiplicative group $\mathrm{gl}_n(R)$. It remains to prove, that if A and B of the special form, described in the implications (1) and (2) then AB is a direct composite of A and B in the sense of the explicit formula for AB. We already know that $AB \in \mathrm{tri}_n^1(R)$ so we only have to regard the (i,k)-th entries with $i < k$. To see this we distinguish two separate cases: If $k > r$ then

$$\mathrm{ent}_{i,k}(AB) \;=\; \sum_{j=1}^{n} a_{i,j}b_{j,k} \;=\; a_{i,k}b_{k,k} + \sum_{j\neq k} a_{i,j}b_{j,k}$$

But as $k > r$ and $j \neq k$ we have $b_{j,k} = 0$ by assumption on B and $b_{k,k} = 1$ is granted, as well. And from this we get $\mathrm{ent}_{i,k}(AB) = a_{i,k}$ for any $k > r$. Alternatively, if $k \leq r$ we compute

$$\mathrm{ent}_{i,k}(AB) \;=\; \sum_{j=1}^{n} a_{i,j}b_{j,k} \;=\; a_{i,i}b_{i,k} + \sum_{j\neq i} a_{i,j}b_{j,k}$$

If $j \leq r$, then by assumption on A we have $a_{i,j} = 0$. If $j > r$, then $k \leq r < j$ implies $k < j$ and hence $b_{j,k} = 0$, as B is an upper triangular matrix. Altogether, with $a_{i,i} = 1$ this is $\mathrm{ent}_{i,k}(AB) = b_{i,k}$. And together this means, that AB is of the form given in the claim. □

Proof of (4.18):

(i) Let us denote $A = (a_{i,j}) \in \mathrm{mat}_{m,n}(R)$ and $B = b_{i,j} \in \mathrm{mat}_{n,m}(R)$. By definition we have $E_{r,s} =$

$(\delta_{i,r}\delta_{j,s})$, hence - for any $i, k \in 1 \ldots n$ we may simply compute the matrix multiplication

$$\mathrm{ent}_{i,k}(AE_{r,s}) \;=\; \sum_{j=1}^{n} a_{i,j}\delta_{j,r}\delta_{k,s} \;=\; a_{i,r}\delta_{k,s}$$

That is the (i,j)-th entry of $AE_{r,s}$ is zero, if $k \neq s$ and if $k = s$, then it simply is $a_{i,r}$. For the k-th column this implies

$$\mathrm{col}_k(AE_{r,s}) \;=\; \delta_{k,s}\,(a_{1,r},\ldots,a_{i,r}) \;=\; \delta_{k,s}\,\mathrm{col}_r(A)$$

Likewise we compute the (i,k)-th entry of $E_{r,s}B$ and use this to evaluate the i-th row of this matrix. This time we get

$$\mathrm{ent}_{i,k}(E_{r,s}B) \;=\; \sum_{j=1}^{n} \delta_{i,r}\delta_{j,s}b_{j,k} \;=\; \delta_{i,r}b_{s,k}$$

$$\mathrm{row}_i(E_{r,s}B) \;=\; \delta_{i,r}\,(b_{s,1},\ldots,b_{s,n}) \;=\; \delta_{i,r}\,\mathrm{row}_s(B)$$

(ii) This identity is a straightforward computation - just be aware that $\delta_{i,j}$ commutes with any other scalar of R and that the sum $\sum_j \delta_{i,j}x_j$ breaks down to x_i. Then we pick up any $p, s \in 1 \ldots n$ and compute

$$\begin{aligned}
\mathrm{ent}_{p,s}(E_{i,j}\,A\,E_{k,l}) &= \sum_{r=1} \mathrm{ent}_{p,r}(E_{i,j}\,A)\,\mathrm{ent}_{r,s}(E_{k,l}) \\
&= \sum_{r=1}\sum_{q=1}^{n} \mathrm{ent}_{p,q}(E_{i,j})\,a_{q,r}\,\mathrm{ent}_{r,s}(E_{k,l}) \\
&= \sum_{r=1}\sum_{q=1}^{n} \delta_{i,p}\,\delta_{j,q}\,a_{q,r}\,\delta_{k,r}\,\delta_{l,s} \\
&= \delta_{i,p}\,a_{j,k}\,\delta_{l,s} \;=\; a_{j,k}\,\mathrm{ent}_{p,s}(E_{i,l})
\end{aligned}$$

(iii) This is an ultimate consequence of (i): clearly $T_{r,s}B = (\mathbb{1}_n + aE_{r,s})B = B + aE_{r,s}B$. Hence the i-th row of $T_{r,s}(a)B$ is given to be

$$\begin{aligned}
\mathrm{row}_i(T_{r,s}(a)B) &= \mathrm{row}_i(B) + a\,\mathrm{col}_k(E_{r,s}B) \\
&= \mathrm{row}_i(B) + \delta_{k,s}\,a\,\mathrm{row}_i(B)
\end{aligned}$$

Likewise we have $AT_{r,s} = A(\mathbb{1}_n + aE_{r,s}) = A + (Aa)E_{r,s}$. And hence the k-th column of $AT_{r,s}(a)$ is given to be

$$\begin{aligned}
\mathrm{col}_k(AT_{r,s}(a)) &= \mathrm{col}_k(A) + \mathrm{col}_k((Aa)E_{r,s}) \\
&= \mathrm{col}_k(A) + \delta_{k,s}\,\mathrm{col}_r(Aa) \\
&= \mathrm{col}_k(A) + \delta_{k,s}\,\mathrm{col}_r(A)\,a
\end{aligned}$$

(iv) Let us denote $x_j = (x_{1,j},\ldots,x_{m,j}) \in R^m$, that is x_j is the j-th column of the matrix $X = x_{i,j} \in \mathrm{mat}_{m,n}(R)$. By definition the diagonal matrix $D := \mathrm{dia}(a_1,\ldots,a_n)$ has $\delta_{i,j}a_j$ as its (i,j)-th entry.

We begin by proving the second equality by simple matrix-multiplication

$$\mathrm{ent}_{i,k}(XD) \;=\; \sum_{j=1}^{n} x_{i,j}\delta_{j,k}a_k \;=\; x_{i,k}a_k$$

Therefore the k-th colums of XD is $\mathrm{col}_k(XD) = (x_{1,k}a_k, \ldots, x_{m,k}a_k)$ which is $x_k a_k$ as we had claimed. In the first equality the x_j are used as rows, that is we actually deal with the transpose X^* of X. Hence the correct ansatz is

$$\mathrm{ent}_{i,k}(DX^*) \;=\; \sum_{j=1}^{n} \delta_{i,j}a_j x_{k,j} \;=\; a_i x_{k,i}$$

Therefore the i-th row of X^* is $\mathrm{row}_i(DX^*) = (a_i x_{1,i}, \ldots, a_i x_{m,i})$ which is $a_i x_i$. Hence we also have shown the first equality.

(v) These equations are straightforward computations using the definition $N_n = (\delta_{i+1,j})$. Let us denote $x_j = (x_{1,j}, \ldots, x_{m,j}) \in R^m$, then $X = (x_{i,j})$ is the $(m \times n)$-matrix composed of the *columns* x_j. Hence the transposed matrix X^* has the *rows* x_j. Thereby for any $i, k \in 1 \ldots n$

$$\mathrm{ent}_{i,k}(XN_n) \;=\; \sum_{j=1}^{n} x_{i,j}\,\delta_{j+1,k} \;=\; \begin{cases} x_{i,k-1} \text{ if } k > 1 \\ 0 \text{ if } k = 1 \end{cases}$$

$$\mathrm{ent}_{i,k}(N_nX^*) \;=\; \sum_{j=1}^{n} \delta_{i+1,j}\,x_{k,j} \;=\; \begin{cases} x_{k,i+1} \text{ if } i < n \\ 0 \text{ if } i = n \end{cases}$$

Once the entries are established, it is easy to evaluate the rows and colums of these matrix products

$$\mathrm{col}_k(N_nX) \;=\; (x_{1,k-1}, \ldots, x_{m,k-1}) \;=\; \begin{cases} x_{k-1} \text{ if } k > 1 \\ 0 \text{ if } k = 1 \end{cases}$$

$$\mathrm{row}_i(N_nX^*) \;=\; (x_{1,i+1}, \ldots, x_{m,i+1}) \;=\; \begin{cases} x_{i+1} \text{ if } i < n \\ 0 \text{ if } i = n \end{cases}$$

(vi) Recall the definition of the permutation matrix $P_\sigma = (\delta_{\sigma(i),j})$. Let us denote $x_j = (x_{1,j}, \ldots, x_{m,j}) \in R^m$ and $X = (x_{i,j})$ again. Then the $(m \times n)$-matrix composed of the *columns* x_j and the transposed matrix X^* has the *rows* x_j. Thereby for any $i, k \in 1 \ldots n$

$$\mathrm{ent}_{i,k}(P_\sigma X^*) \;=\; \sum_{j=1}^{n} \delta_{\sigma(i),j}\,x_{k,j} \;=\; x_{k,\sigma(i)}$$

Hence the i-th row of $P_\sigma X^*$ is $(x_{1,\sigma(i)}, \ldots, x_{m,\sigma(i)})$ which is nothing but $x_{\sigma(i)}$. Now we supposed that σ is bijective, that is the equation $\sigma(j) = k$ has the unique solution $j = \sigma^{-1}(k)$. Then we get

$$\mathrm{ent}_{i,k}(XP_\sigma) \;=\; \sum_{j=1}^{n} x_{i,j}\,\delta_{\sigma(j),k} \;=\; x_{i,\sigma^{-1}(k)}$$

Thereby the k-th column of XP_σ is $(x_{1,\sigma^{-1}(k)}, \ldots, x_{m,\sigma^{-1}(k)})$ which nothing but $x_{\sigma^{-1}(k)}$. Altogether we have proved the equalities given.

□

Proof of (4.21):

(i) It is clear that the map given is an R-module homomorphism, as the operations are point-wise, in both cases. The bijectivity is trivial as well. As also $(1,\dots,1) \mapsto \mathrm{dia}(1,\dots,1) = \mathbb{1}_n$ it only remains to prove, that the map also transfers the respective multiplications. Hence consider any $a_1,\dots,a_n$ and $b_1,\dots,b_n \in R$. Using (4.18.(ii)) we find

$$\begin{aligned} & \mathrm{dia}(a_1,\dots,a_n)\,\mathrm{dia}(b_1,\dots,b_n) \\ = & \left(\sum_{i=1}^{n} a_i\,E_{i,i}\right)\left(\sum_{j=1}^{n} b_j\,E_{j,j}\right) \\ = & \sum_{i=1}^{n}\sum_{j=1}^{n} a_i\,b_j\,E_{i,i}\,E_{j,j} \\ = & \sum_{i=1}^{n}\sum_{j=1}^{n} a_i\,b_j\,\delta_{i,j}\,E_{i,j} \\ = & \sum_{i=1}^{n} a_i\,b_i\,E_{i,i} \;=\; \mathrm{dia}(a_1\,b_1,\dots,a_n\,b_n) \end{aligned}$$

That is we have shown that the map given truly is an isomorphism of R-algebras. Also $\mathrm{dia}(a_1,\dots,a_n)\,\mathrm{dia}(b_1,\dots,b$ $\mathbb{1}_n = \mathrm{dia}(1,\dots,1)$ is satisfied if and only if $a_ib_i = 1$ for any $i \in 1\dots n$. Likewise $b_ia_i = 1$ for any $i \in 1\dots n$. But this is equivalent to $a_i \in R^*$ being a unit in R with inverse $b_i = a_i^{-1}$. Hence $\mathrm{dia}(a_1,\dots,a_n)$ is invertible if and only $a_i \in R^*$ for any $i \in 1\dots n$.

(ii) This is just a special case of (i) - the i-th entry is fixed to be a and the other $n-1$ entries are 1, which always is a unit $1 \in R^*$ of R.

(iii) Using (4.18.(ii)) again, the multiplication property of the transposition matrices is an easy computation

$$\begin{aligned} T_{i,j}(a)\,T_{i,j} &= (\mathbb{1}_n + aE_{i,j})(\mathbb{1}_n + bE_{i,j}) \\ &= \mathbb{1}_n + (a+b)\,E_{i,j} + ab\,E_{i,j}^2 \\ &= \mathbb{1}_n + (a+b)\,E_{i,j} \\ &= T_{i,j}(a+b) \end{aligned}$$

Hereby $E_{i,j}^2 = 0$, as we have assumed $i \neq j$ to be distinct. Now, as $T_{i,j}(0) = \mathbb{1}_n$ we see that $T_{i,j}(a)T_{i,j}(-a) = \mathbb{1}_n$ and of course also $T_{i,j}(-a)T_{i,j}(a) = \mathbb{1}_n$. That is $T_{i,j}(a)$ is invertible and the inverse is given to be $T_{i,j}(-a)$.

(iv) Let $\mathcal{E} = \{\,e_1,\dots,e_n\,\}$ be the Euclidean basis of R^n. By definition of the permutation matrices the i-th row of P_τ is $x_i := e_{\tau(i)}$. We now use the multiplication formula (4.18.(vi)) for permutation matrices, then the i-th row of $P_\sigma P_\tau$ is $x_{\sigma(i)}$ and this is $e_{\tau(\sigma(i))}$ in turn. Altogether we find

$$P_\sigma\,P_\tau \;=\; P_\sigma \begin{pmatrix} — & e_{\tau(1)} & — \\ & \vdots & \\ — & e_{\tau(n)} & — \end{pmatrix} = \begin{pmatrix} — & e_{\tau\sigma(1)} & — \\ & \vdots & \\ — & e_{\tau\sigma(n)} & — \end{pmatrix} = P_{\tau\sigma}$$

Again it is clear that truly $P_{id} = \mathbb{1}_n$. Hence if σ is bijective, then $P_\sigma P_{\sigma^{-1}} = P_{id} = \mathbb{1}_n$ and analogously $P_\sigma^{-1} P_\sigma = P_{id} = \mathbb{1}_n$ such that P_σ is invertible and the inverse is given to be $P_{\sigma^{-1}}$. Conversely suppose $P_\sigma P_\tau = \mathbb{1}_n$ and $P_\tau P_\sigma = \mathbb{1}_n$. By comparing coefficients we find that $\tau\sigma = id$ and $\sigma\tau = id$, that is τ is the inverse function of σ and in particular σ is bijective.

It remains to prove that the transpose P_σ^* also is the inverse P_σ^{-1}. As P_σ has been defined in such a way, as $\mathrm{col}_i(P_\sigma) = e_{\sigma(i)}$ we find that the transpose of P_σ is given by $\mathrm{row}_i(P_\sigma^*) = e_{\sigma(i)}$. Then we can use (4.18.(vi)) again, to compute

$$\begin{aligned} P_\sigma^* P_\sigma &= \begin{pmatrix} | & | & & | \\ e_{\sigma(1)} & e_{\sigma(2)} & \cdots & e_{\sigma(n)} \\ | & | & & | \end{pmatrix} P_\sigma \\ &= \begin{pmatrix} | & | & & | \\ e_{\sigma^{-1}((\sigma(1))} & e_{\sigma^{-1}((\sigma(2))} & \cdots & e_{\sigma^{-1}((\sigma(n))} \\ | & | & & | \end{pmatrix} = \mathbb{1}_n \end{aligned}$$

And as we have already proved, that P_σ is invertible we can multiply the equation $P_\sigma^* P_\sigma = \mathbb{1}_n$ with P_σ^{-1} from the right to find

$$P_\sigma^* = P_\sigma^*(P_\sigma P_\sigma^{-1}) = (P_\sigma^* P_\sigma) P_\sigma^{-1} = P_\sigma^{-1}$$

(v) By associativity of the matrix multiplication we can evaluate $P_\varrho A$ first: But then P_ϱ permutes the rows of A, by (4.18.(vi)) and this is $P_\varrho A = (a_{\varrho(i),j})$. Multiplying $P_\sigma^{-1} = P_{\sigma^{-1}}$ from the right permutes the columns of this matrix yields and hence

$$P_\varrho A P_\sigma^{-1} = \big(P_\varrho A\big) P_{\sigma^{-1}} = \big(a_{\varrho(i),j}\big) P_{\sigma^{-1}} = \big(a_{\varrho(i),\sigma(j)}\big)$$

□

Proof of (4.40):

- Let $\mathcal{M} = (m_1, \ldots, m_s)$ be an ordered basis of M and consider a scalar $a \in R$ and two vectors $x = \sum_j x_j m_j$ and $y = \sum_j y_j m_j \in M$. Then it is clear, that $ax = \sum_j a x_j m_j$ and $x + y = \sum_j (x_j + y_j) m_j$ and thereby we get $[ax]_j = a x_j = a[x]_j$ and $[x+y]_j = x_j + y_j = [x]_j + [y]_j$. And as this is true for any $j \in 1 \ldots s$ and $[x]_\mathcal{M} = ([x]_1, \ldots, [x]_s)$ we conclude $[ax]_\mathcal{M} = a[x]_\mathcal{M}$ and $[x+y]_\mathcal{M} = [x]_\mathcal{M} + [y]_\mathcal{M}$.
- Likewise let $\mathcal{N} = (n_1, \ldots, n_r)$ be an ordered basis of N and consider two R-module-homomorphisms φ and $\psi : M \to N$. Let $A = (a_{i,j}) = [\varphi]_\mathcal{M}^\mathcal{N}$ and $B = (b_{i,j}) = [\psi]_\mathcal{M}^\mathcal{N}$ be the matrix representations of φ and ψ respectively. Then we compute

$$\begin{aligned} (a\varphi)(m_j) &= a\varphi(m_j) = a \sum_{i=1}^r a_{i,j} n_i = \sum_{i=1}^r a a_{i,j} n_i \\ (\varphi + \psi)(m_j) &= \varphi(m_j) + \psi(m_j) \\ &= \sum_{i=1}^r a_{i,j} n_i + \sum_{i=1}^r b_{i,j} n_i = \sum_{i=1}^r (a_{i,j} + b_{i,j}) n_i \end{aligned}$$

That is for any $j \in 1 \ldots s$ and any $i \in 1 \ldots r$ we find $[a\varphi]_{i,j} = a a_{i,j} = a[\varphi]_{i,j}$ and $[\varphi + \psi]_{i,j} =$

$a_{i,j} + b_{i,j} = [\varphi]_{i,j} + [\psi]_{i,j}$. And as this is true for any combination of i and j this yields to following identities for the matrices $[a\varphi]^{\mathcal{N}}_{\mathcal{M}} = a[\varphi]^{\mathcal{N}}_{\mathcal{M}}$ and $[\varphi + \psi]^{\mathcal{N}}_{\mathcal{M}} = [\varphi]^{\mathcal{N}}_{\mathcal{M}} + [\psi]^{\mathcal{N}}_{\mathcal{M}}$.

- Finally assume that R is commutative and let $\mathcal{L} = (\ell_1, \ldots, \ell_t)$ be an ordered basis of L and we consider $x \in L$ and the R-module-homomorphisms $\varphi : L \to M$ and $\psi : M \to N$. If now $[x]_{\mathcal{L}} = u = (u_1, \ldots, u_t)$ and $[\varphi]^{\mathcal{M}}_{\mathcal{L}} = A = (a_{j,k})$ and $[\psi]^{\mathcal{N}}_{\mathcal{M}} = B = (b_{i,j})$ are the respective basis representations, then we compute

$$\begin{aligned}
\varphi(x) &= \varphi\left(\sum_{k=1} u_k \ell_k\right) = \sum_{k=1}^{t} u_k \varphi(\ell_k) \\
&= \sum_{k=1}^{t} u_k \sum_{j=1}^{s} a_{j,k} m_j \\
&= \sum_{j=1}^{s} \left(\sum_{k=1}^{t} a_{j,k} u_k\right) m_j \\
&= \sum_{j=1}^{s} [Au]_j \, m_j
\end{aligned}$$

That is $[\varphi(x)]_j = [Au]_j$ and as this is true for any $j \in 1 \ldots s$ we have shown, that $[\varphi(x)]_{\mathcal{M}} = Au = [\varphi]^{\mathcal{M}}_{\mathcal{L}} [x]_{\mathcal{L}}$. In complete analogy

$$\begin{aligned}
\psi\varphi(\ell_k) &= \psi(\varphi(\ell_k)) = \psi\left(\sum_{j=1}^{s} a_{j,k} m_j\right) \\
&= \sum_{j=1}^{s} a_{j,k} \psi(m_j) = \sum_{j=1}^{s} a_{j,k} \sum_{i=1}^{r} b_{i,j} n_i \\
&= \sum_{i=1}^{r} \left(\sum_{j=1}^{s} b_{i,j} a_{j,k}\right) n_i = \sum_{i=1}^{r} [BA]_{i,k} \, n_i
\end{aligned}$$

That is we have found that the (i,k)-th coefficient of the matrix of $\psi\varphi$ is given to be $[\psi\varphi]_{i,k} = [\psi\varphi(\ell_k)]_i = [BA]_{i,k}$ and as this is true for any $i \in 1 \ldots r$ and $k \in 1 \ldots t$ this is $[\psi\varphi]^{\mathcal{N}}_{\mathcal{L}} = BA = [\psi]^{\mathcal{N}}_{\mathcal{M}} [\varphi]^{\mathcal{M}}_{\mathcal{L}}$.

- At last we take a look at the map $\varphi \mapsto A$, where $\varphi \in \mathrm{mhom}(M,N)$ and $A = [\varphi]^{\mathcal{N}}_{\mathcal{M}} \in \mathrm{mat}_{r,s}(R)$. We have shown already, the this is a homomorphism. It remains to verify, that it is bijective, more precisely that the inverse map is $A \mapsto \varphi_A$ [where φ_A has been defined in the claim (4.40]. For ease of notation let us fix $\mathcal{M}$ and $\mathcal{M}$, that is we abbreviate $[x] = [x]_{\mathcal{M}}$ for any $x \in M$, $[y] = [y]_{\mathcal{N}}$ for any $y \in N$ and $[\varphi] = [\varphi]^{\mathcal{N}}_{\mathcal{M}}$ for any $\varphi : M \to N$.

 In a first step we will show $\varphi \mapsto [\varphi] \mapsto \varphi_{[\varphi]} = \varphi$ for any $\varphi : M \to N$. But this is straightforward: By definition we have $[\varphi_A(x)] = A[x]$ for any $x \in M$ and thereby

$$\Big[\varphi_{[\varphi]}(x)\Big] = [\varphi][x] = [\varphi(x)]$$

 Since $\mathcal{N}$ is a basis of N it is clear, that $y \mapsto [y]$ is bijective, from which we find that $\varphi(x) = \varphi_{[\varphi]}(x)$ for any $x \in M$ and hence $\varphi = \varphi_{[\varphi]}$. Conversely for $A \mapsto \varphi_A \mapsto [\varphi_A] = A$ we first note, that

$[m_j] = e_j \in \mathcal{E}(s)$ is an Euclidean base vector. Thereby we get

$$\varphi_A(m_j) \;=\; \sum_{i=1}^{r} [Ae_j]_i \, n_i \;=\; \sum_{i=1}^{r} a_{i,j} \, n_i$$

That is $[\varphi_A(m_j)]_i = a_{i,j}$ and hence $[\varphi_A(m_j)] = \mathrm{col}_j(A)$. But as $[\varphi_A(m_j)]$ is the j-th column of $[\varphi_A]$ (refer to remark (4.36) for this) we have established $[\varphi_A] = A$. Thus $\varphi \mapsto [\varphi]$ has an inverse map (namely $A \mapsto \varphi_A$) and hence is bijective.

- It only remains to prove the correspondence of isomorphisms and invertible matrices: Fix the ordered bases $\mathcal{M} = (m_1, \ldots, m_s)$ and $\mathcal{N} = (n_1, \ldots, n_r)$ of M and N respectively, again. If φ is bijective, let us denote $A := [\varphi]^{\mathcal{N}}_{\mathcal{M}}$ and $B := [\varphi^{-1}]^{\mathcal{M}}_{\mathcal{N}}$. Then we have just seen, that

$$\mathbb{1}_s \;=\; [\mathbb{1}_M]^{\mathcal{M}}_{\mathcal{M}} \;=\; [\varphi^{-1}\varphi]^{\mathcal{M}}_{\mathcal{M}} \;=\; [\varphi^{-1}]^{\mathcal{M}}_{\mathcal{N}} \, [\varphi]^{\mathcal{N}}_{\mathcal{M}} \;=\; BA$$

That is we have $BA = \mathbb{1}_s$ and in complete analogy we find $AB = \mathbb{1}_r$. Together this is $B = A^{-1}$, as we had claimed. Conversely, if A is invertible, then we define $\psi : N \to M$ to be the homomorphism defined by A^{-1}, that is $\psi := \varphi_{A^{-1}}$. Then for any $x \in M$ we may compute

$$[\psi\varphi(x)]_{\mathcal{M}} \;=\; [\psi]^{\mathcal{M}}_{\mathcal{N}} \, [\varphi]^{\mathcal{N}}_{\mathcal{M}} \, [x]_{\mathcal{M}} \;=\; A^{-1} \, A \, [x]_{\mathcal{M}} \;=\; [x]_{\mathcal{M}}$$

This implies $\psi\varphi(x) = x$ and as x has been arbitrary, this is $\psi\varphi = \mathbb{1}_M$. In complete analogy we have $\varphi\psi = \mathbb{1}_N$ and therefore φ is bijective, with inverse map ψ.

□

Proof of (4.42):

(i) First of all it is clear, that $r = s$ is necessary for any of the statements: In (a) φ is an isomorphism and hence $r = \dim(M) = \dim(N) = s$ and in (b) and (c) only square matrices are invertible. Thus we may assume $r = s$ throughout the rest of the proof.

We start with (a) $\implies$ (c): Let $\mathcal{M} = (m_1, \ldots, m_s)$ and $\mathcal{N} = (n_1, \ldots, n_r)$ be ordered bases of M and N respectively. Then it is clear that $\mathbb{1}_s = [\mathbb{1}_M]^{\mathcal{M}}_{\mathcal{M}}$ since $\mathbb{1}_M(m_j) = m_j = \sum_i \delta_{i,j} m_i$ for any $j \in 1 \ldots s$. Now as $\varphi^{-1}\varphi = \mathbb{1}_M$ and $\varphi\varphi^{-1} = \mathbb{1}_N$ we may use (4.40) to compute

$$\mathbb{1}_s \;=\; [\mathbb{1}_M]^{\mathcal{M}}_{\mathcal{M}} \;=\; [\varphi^{-1}\varphi]^{\mathcal{M}}_{\mathcal{M}} \;=\; [\varphi^{-1}]^{\mathcal{N}}_{\mathcal{M}} \, [\varphi]^{\mathcal{M}}_{\mathcal{N}}$$

Thus if $A := [\varphi]^{\mathcal{M}}_{\mathcal{N}}$ and $B := [\varphi^{-1}]^{\mathcal{N}}_{\mathcal{M}}$ then we have $AB = \mathbb{1}_s$. But as we also find $BA = \mathbb{1}_r$ we see that A is invertible, with inverse matrix B. Hereby $BA = \mathbb{1}_r$ can be seen from

$$\mathbb{1}_r \;=\; [\mathbb{1}_N]^{\mathcal{N}}_{\mathcal{N}} \;=\; [\varphi\varphi^{-1}]^{\mathcal{N}}_{\mathcal{N}} \;=\; [\varphi]^{\mathcal{M}}_{\mathcal{N}} \, [\varphi^{-1}]^{\mathcal{N}}_{\mathcal{M}}$$

The implication (c) $\implies$ (b) is trivial: Note that by assumption on M and N there are some ordered bases $\mathcal{M}$ of M and $\mathcal{N}$ of N in the first place. So it only remains to verify (b) $\implies$ (a): Again let $A := [\varphi]^{\mathcal{M}}_{\mathcal{N}}$ and define $\psi : N \to M$ by virtue of $[\psi]^{\mathcal{N}}_{\mathcal{M}} = A^{-1}$ that is $\psi := \varphi_{A^{-1}}$ in the notation of (4.40). Then we compute

$$[\psi\varphi]^{\mathcal{M}}_{\mathcal{M}} \;=\; [\psi]^{\mathcal{N}}_{\mathcal{M}} \, [\varphi]^{\mathcal{M}}_{\mathcal{N}} \;=\; A^{-1}A \;=\; \mathbb{1}_s \;=\; [\mathbb{1}_M]^{\mathcal{M}}_{\mathcal{M}}$$

But as $\varphi \mapsto [\varphi]_{\mathcal{M}}^{\mathcal{M}}$ is bijective we find $\psi\varphi = \mathbb{1}_M$. In complete analogy we get $\varphi\psi = \mathbb{1}_n$ such that φ is bijective, with inverse map $\varphi^{-1} = \psi$.

(iii) We have to prove that $\mathcal{M}' := (m'_1, \ldots, m'_s)$ truly is an ordered basis of M. The cornerstone of this reasoning is the following computation for any $x = (x_1, \ldots, x_s) \in R^s$ take a look at

$$\begin{aligned}
\sum_{j=1}^{s} x_j\, m'_j &= \sum_{j=1}^{s} x_j \sum_{i=1}^{s} t_{i,j}\, m_i \\
&= \sum_{i=1}^{s} \left(\sum_{j=1}^{s} x_j\, t_{i,j} \right) m_i \\
&= \sum_{i=1}^{s} \left(\sum_{j=1}^{s} t_{i,j}\, x_j \right) m_i \\
&= \sum_{i=1}^{s} [Tx]_i\; m_i
\end{aligned}$$

Thus if we are given any $m \in M$ pick up some $y = (y_1, \ldots, y_s) \in R^s$ such that $m = \sum_i y_i m_i$. Then $x = (x_1, \ldots, x_s) := T^{-1}y \in R^s$ satisfies $[Tx]_i = y_i$ and hence $\sum_j x_j m'_j = \sum_i y_i m_i = m$. Thus for any $m \in M$ there is some $x \in R^s$ with $m = \sum_j x_j m'_j$ which means that $\{ m'_1, \ldots, m'_s \}$ generates M. But this set also is linearly independent: If $\sum_j x_j m'_j = 0$ then also $\sum_i [Tx]_i m_i = 0$, as these sums are equal. But as the m_i form a basis of M this means $[Tx]_i = 0$ for any $i \in 1 \ldots s$ and hence $Tx = 0$. But as T is invertible this can only happen if $x = 0$ such that $\{ m'_1, \ldots, m'_s \}$ also is linearly independent and hence a basis. Of course the m'_i thereby also are pairwise distinct, as $m'_i - m'_j = 0$ cannot occur for any $i \neq j \in 1 \ldots s$.

By construction of $\mathcal{M}'$ we have $\mathbb{1}_M(m'_j) = m'_j = \sum_i t_{i,j} m_i$. Therefore $[\mathbb{1}(m'_j)]_{\mathcal{M}} = (t_{1,j}, \ldots, t_{s,j}) = \mathrm{col}_j(T)$ such that $[\mathbb{1}_M]_{\mathcal{M}'}^{\mathcal{M}} = T$. Also $T\,[\mathbb{1}_M]_{\mathcal{M}}^{\mathcal{M}'} = [\mathbb{1}_M]_{\mathcal{M}'}^{\mathcal{M}} [\mathbb{1}_M]_{\mathcal{M}}^{\mathcal{M}'} = [\mathbb{1}_M]_{\mathcal{M}} = \mathbb{1}_n$ and likewise $[\mathbb{1}_M]_{\mathcal{M}}^{\mathcal{M}'}\, T = \mathbb{1}_n$. Together this implies $[\mathbb{1}_M]_{\mathcal{M}}^{\mathcal{M}'} = T^{-1}$.

(ii) Since $\mathbb{1}_M$ is invertible we already know that $[\mathbb{1}_M]_{\mathcal{M}}^{\mathcal{M}'}$ is invertible by (b) $\implies$ (a) in (i). Thus the implication (b) $\implies$ (a) of (ii) is just a special case of (i). To prove converse direction (a) $\implies$ (b) we start with *any* ordered basis $\mathcal{M}' = (m'_1, \ldots, m'_r)$ of M and define

$$m_j \;:=\; \sum_{i=1}^{s} a_{i,j}\, m'_i \;\in\; M$$

where $j \in 1 \ldots s$ and $A = (a_{i,j})$. As A is invertible, (iii) tells us, that $\mathcal{M} = (m_1, \ldots, m_s)$ is another ordered basis of M and that $[\mathbb{1}_M]_{\mathcal{M}}^{\mathcal{M}'} = A$ and this already is (b).

(iv) By (ii) we already know that $S = [\mathbb{1}_M]_{\mathcal{M}'}^{\mathcal{M}}$ and $T = [\mathbb{1}_N]_{\mathcal{N}}^{\mathcal{N}'}$ are invertible matrices. But as $\varphi = \mathbb{1}_N \varphi \mathbb{1}_M$ trivially is true, we may use (4.40) once again, to compute

$$[\varphi]_{\mathcal{M}'}^{\mathcal{N}'} \;=\; [\mathbb{1}_N \varphi \mathbb{1}_M]_{\mathcal{M}'}^{\mathcal{N}'} \;=\; [\mathbb{1}_N]_{\mathcal{N}}^{\mathcal{N}'} [\varphi]_{\mathcal{M}}^{\mathcal{N}} [\mathbb{1}_M]_{\mathcal{M}'}^{\mathcal{M}} \;=\; T[\varphi]_{\mathcal{M}}^{\mathcal{N}} S$$

(v) By (iv) we have $[\varphi]_{\mathcal{M}'} = T[\varphi]_{\mathcal{M}} S$ where $T = [\mathbb{1}_M]_{\mathcal{M}}^{\mathcal{M}'}$ and $S = [\mathbb{1}_M]_{\mathcal{M}'}^{\mathcal{M}}$. But by the same reasoning

as in (i) we find $S = T^{-1}$ due to

$$TS \;=\; [\mathbb{1}_M]^{\mathcal{M}'}_{\mathcal{M}}[\mathbb{1}_M]^{\mathcal{M}}_{\mathcal{M}'} \;=\; [\mathbb{1}_M]^{\mathcal{M}}_{\mathcal{M}} \;=\; \mathbb{1}_s$$

$$ST \;=\; [\mathbb{1}_M]^{\mathcal{M}'}_{\mathcal{M}}[\mathbb{1}_M]^{\mathcal{M}'}_{\mathcal{M}} \;=\; [\mathbb{1}_M]^{\mathcal{M}'}_{\mathcal{M}'} \;=\; \mathbb{1}_s$$

□

Proof of (4.45):

(i) Let us first prove that $\sim$ is an equivalence relation: First of all, we have $A \sim A$, since $A = \mathbb{1}_m A \mathbb{1}_n$. Also if $A \sim B$, that is $B = SAT$, then $A = S^{-1}BT^{-1}$ such that $B \sim A$. If $A \sim B$ and $C \in \mathrm{mat}_{m,n}(R)$ is another matrix, with $B \sim C$, that is $B = SAT$ and $C = UBV$ for some S, $U \in \mathrm{gl}_m(R)$ and some T, $V \in \mathrm{gl}_n(R)$, then $C = UBV = U(SAT)V = (US)A(TV)$. Thereby $US \in \mathrm{gl}_m(R)$ is invertible, with inverse $(US)^{-1} = S^{-1}U^{-1}$ and likewise $TV \in \mathrm{gl}_n(R)$ is invertible with inverse $(TV)^{-1} = V^{-1}T^{-1}$. That is $A \sim C$ such that all three properties of an equivalence relation are satisfied.

(i) In (i) we also claimed the equivalence of (a) $A \sim B$ and (b) $A = [\varphi]^{\mathcal{M}}_{\mathcal{N}}$ and $B = [\varphi]^{\mathcal{M}'}_{\mathcal{N}'}$ for some $\varphi : R^n \to R^m$. Thereby (b) $\implies$ (a) has already been proved in (4.42.(iii)). Conversely for (a) $\implies$ (b) we have $B = SAT$ for some $S \in \mathrm{gl}_m(R)$ and $T \in \mathrm{gl}_n(R)$. Now take $\varphi(x) := Ax$, $\mathcal{M}' := \mathcal{E}(m)$ the Euclidean basis of R^m and $\mathcal{N} := \mathcal{E}(n)$ the Euclidean basis of R^n. Further let $\mathcal{M} := S\mathcal{M}'$ and $\mathcal{N}' := T\mathcal{N}$. As $T : R^n \to R^n$ is an automorphism the image $\mathcal{N}'$ of $\mathcal{N}$ under T is an ordered basis of R^n again. Likewise $\mathcal{M}$ is an ordered basis of R^m. By construction it is clear, that

$$[\varphi]^{\mathcal{M}}_{\mathcal{N}} \;=\; [\varphi]^{\mathcal{E}(m)}_{\mathcal{E}(n)} \;=\; A$$

$$[\mathbb{1}]^{\mathcal{M}'}_{\mathcal{M}} \;=\; [\mathbb{1}]^{\mathcal{E}(m)}_{S\mathcal{E}(m)} \;=\; S$$

$$[\mathbb{1}]^{\mathcal{N}}_{\mathcal{N}'} \;=\; [\mathbb{1}]^{\mathcal{E}(n)}_{T\mathcal{E}(n)} \;=\; T$$

Therefore $B = SAT = [\mathbb{1}]^{\mathcal{N}}_{\mathcal{N}'}[\varphi]^{\mathcal{M}}_{\mathcal{N}}[\mathbb{1}]^{\mathcal{N}}_{\mathcal{N}'} = [\varphi]^{\mathcal{M}'}_{\mathcal{N}'}$ such that we have (b).

(ii) We will now prove that $\approx$ is an equivalence relation, as well: First of all, $A \approx A$ again, since $A = \mathbb{1}_n A \mathbb{1}_n^{-1}$. Also if $A \sim B$, that is $B = TAT^{-1}$ then $B = T^{-1}BT = T^{-1}B(T^{-1})^{-1}$. But as $T^{-1} \in \mathrm{gl}_n(R)$ again, this is $B \approx A$. If $A \approx B$ and $C \in \mathrm{mat}_n(R)$ is another matrix, with $B \approx C$, that is $B = TAT^{-1}$ and $C = UBU^{-1}$ for some T and $U \in \mathrm{gl}_n(R)$, then $C = UBU^{-1} = U(TAT^{-1})U^{-1} = (UT)A(T^{-1}U^{-1}) = (UT)A(UT)^{-1}$ and as $UT \in \mathrm{gl}_n(R)$ is invertible again, we find $A \approx C$ such that all three properties of an equivalence relation are satisfied.

(ii) In (ii) we also claimed the equivalence of (a) $A \approx B$ and (b) $A = [\varphi]_{\mathcal{M}}$ and $B = [\varphi]_{\mathcal{N}}$ for some $\varphi : R^n \to R^n$. Thereby (b) $\implies$ (a) has already been proved in (4.42.(v)). Conversely for (a) $\implies$ (b) we have $B = TAT^{-1}$ for some $T \in \mathrm{gl}_n(R)$. Analogous to (i) above, we let $\varphi(x) := Ax$ and $\mathcal{M} := \mathcal{E}(n)$ be the Euclidean basis of R^n. Now $\mathcal{N} := T^{-1}\mathcal{M}$, then it is clear, that

$$[\varphi]_{\mathcal{M}} \;=\; [\varphi]_{\mathcal{E}(n)} \;=\; A$$

$$[\mathbb{1}]_{\mathcal{N}}^{\mathcal{M}} \;=\; [\mathbb{1}]_{T^{-1}\mathcal{E}_{(n)}}^{\mathcal{E}_{(n)}} \;=\; T^{-1}$$

$$[\mathbb{1}]_{\mathcal{M}}^{\mathcal{N}} \;=\; \left([\mathbb{1}]_{\mathcal{N}}^{\mathcal{M}}\right)^{-1} \;=\; \left(T^{-1}\right)^{-1} \;=\; T$$

Therefore $B = TAT^{-1} = [\mathbb{1}]_{\mathcal{M}}^{\mathcal{N}}[\varphi]_{\mathcal{M}}[\mathbb{1}]_{\mathcal{N}}^{\mathcal{M}} = [\varphi]_{\mathcal{N}}$ such that (b) again.

(iii) By definition the image of B is the set of all $SATx$ where $x \in R^n$. As T is surjective we can take to $y := Tx \in \mathbb{R}^n$ and thereby compute

$$\begin{aligned}\operatorname{im}(B) \;&=\; \{\, SATx \mid x \in R^n \,\} \;=\; \{\, SAy \mid y \in R^n \,\} \\ &=\; S\,\{\, Ay \mid y \in R^n \,\} \;=\; S\operatorname{im}(A)\end{aligned}$$

By definition the kernel of B is the set of all $x \in \mathbb{R}^n$ such that $SATx = 0$. But as S is injective, this is equivalent to $ATx = 0$. Now let $y := Tx$ that is $x = T^{-1}y$, then we can compute

$$\begin{aligned}\operatorname{kn}(B) \;&=\; \{\, x \in R^n \mid SATx = 0 \,\} \;=\; \{\, x \in R^n \mid ATx = 0 \,\} \\ &=\; \left\{\, T^{-1}y \mid Ay = 0 \,\right\} \;=\; T^{-1}\operatorname{kn}(A)\end{aligned}$$

□

Proof of (4.46):

(i) By definition $\operatorname{ent}_{i,j}([\varphi]_{\mathcal{M}}) = [\varphi(m_j)]_i$. We consider any $j \le r$, if P is invariant under φ, then $\varphi(m_j) \in P = \operatorname{Lh}\{\, m_1, \ldots, m_r \,\}$ and hence the i-th coefficient in the basis representation of $\varphi(m_j)$ is 0, whenever $i > r$. This already is $A_{2,1} = 0$ and conversely, if $A_{2,1} = 0$ any $x \in P$ is mapped to $\varphi(x) \in \operatorname{Lh}\{\, m_1, \ldots, m_r \,\} = P$ again, such that $\varphi(P) \subseteq P$.

(ii) Let us abbreviate $A := [\varphi_1 \oplus \varphi_2]_{\mathcal{N}}^{\mathcal{M}}$ and $A_{k,k} = [\varphi_k]_{\mathcal{N}^k}^{\mathcal{M}^k}$ for $k = 1$ and $k = 2$. Then we have to show $A = A_{1,1} \oplus A_{2,2}$. In terms of (i) that is $A_{2,1} = 0$ and $A_{1,2} = 0$. But as $\varphi_1 \oplus \varphi_2(n_j^1, 0) = (\varphi_1(n_j^1), 0) \in N^1 \oplus 0$ we see that $N^1 \oplus 0$ is invariant under $\varphi_1 \oplus \varphi_2$ such that $A_{2,1} = 0$. Likewise $0 \oplus N^2$ is invariant under $\varphi_1 \oplus \varphi_2$ and in complete analogy this implies $A_{1,2} = 0$.

(iii) If $M = M_1 \oplus \cdots \oplus M_r$ then (as any M_i is free) choose bases $\mathcal{N}^i$ of M_i and let $\mathcal{N} := \mathcal{N}^1 \cup \cdots \cup \mathcal{N}^r$. Order $\mathcal{N}$ is such a way, that for $1 \le i < j \le r$ any $n_i \in M_i$ is in front of $n_j \in M_j$. The order inside $\mathcal{N}^i$ is irrelevant. As $\varphi(M_i) \subseteq M_i$ we may restrict φ to $\varphi_i : M_i \to M_i : x \mapsto \varphi(x)$. Now let $A_i := [\varphi_i]_{\mathcal{N}^i}$, then by (induction on) (ii) it is clear that $[\varphi]_{\mathcal{N}} = B := A_1 \oplus \cdots \oplus A_r$. As both $\mathcal{M}$ and $\mathcal{N}$ are bases of M, (4.42.(v)) implies $B = TAT^{-1}$ for $T = [\mathbb{1}]_{\mathcal{M}}^{\mathcal{N}}$, in particular $A \approx B$.

Conversely if $TAT^{-1} = B := A_1 \oplus \cdots \oplus A_r$ for some $T \in \mathrm{gl}_n(R)$, say $T^{-1} = (s_{i,j}) \in \mathrm{mat}_n(R)$. Recall that $\mathcal{M} = (m_1, \ldots, m_n)$ is a basis of M, then we define

$$b_j \;:=\; \sum_{i=1}^{n} s_{i,j} m_i \;\in\; M$$

As T^{-1} is invertible $\mathcal{B} := (b_1, \ldots, b_n)$ is another ordered basis of M, due to (4.42.(iii)) and we also get $T^{-1} = [\mathbb{1}]_{\mathcal{B}}^{\mathcal{M}}$ and likewise $T = [\mathbb{1}]_{\mathcal{M}}^{\mathcal{B}}$. But then B is the matrix representation of φ in $\mathcal{B}$, as

$$[\varphi]_{\mathcal{B}} \;=\; [\mathbb{1}]_{\mathcal{M}}^{\mathcal{B}}\,[\varphi]_{\mathcal{M}}\,[\mathbb{1}]_{\mathcal{B}}^{\mathcal{M}} \;=\; TAT^{-1} \;=\; B$$

Now define M_i (for $i \in 1 \dots r$) to be the sub-module of M generated by $b_{\ell(i)+1}$ to $b_{\ell(i)+k(i)}$ where $\ell(i) := k(1) + \cdots + k(i-1)$ and in particular $\ell(1) = 0$. That is

$$\begin{aligned} M_1 &:= \mathsf{Lh}\{\, b_j \mid 1 \le j \le k(1) \,\} \\ M_2 &:= \mathsf{Lh}\{\, b_j \mid k(1)+1 \le j \le k(1)+k(2) \,\} \\ &\vdots \qquad\quad \vdots \\ M_r &:= \mathsf{Lh}\{\, b_j \mid n-k(r)+1 \le j \le n \,\} \end{aligned}$$

By construction the M_i are free (as they are generated by linearly independent sets) and $M = M_1 \oplus \cdots \oplus M_r$ are we only partitioned the basis $\{\, b_1, \dots, b_n \,\}$ of M. But the M_i also are φ-invariant: For ease of notation take a look at $\varphi(b_1)$: Then

$$[\varphi(b_1)]_{\mathcal{B}} \;=\; [\varphi]_{\mathcal{B}}\,[b_1]_{\mathcal{B}} \;=\; B\,e_1 \;\in\; \mathsf{Lh}\{\, e_1, \dots, e_{k(1)} \,\}$$

Taking the preimage under the isomorphism $x \mapsto [x]_{\mathcal{B}}$ we hence get $\varphi(b_1) \in M_1$ again. In complete analogy we find $\varphi(b_j) \in M_i$ for any $b_j \in M_i$ and hence $\varphi(M_i) \subseteq M_i$. Altogether this is (a).

□

Proof of (4.47):
Let us denote the set of bilinear forms $M \oplus N \to R$ by $\mathrm{bil}(M \oplus N, R) := \{\, b : M \oplus N \to R \mid b \text{ is bilinear} \,\}$. Then we need to show the bijective correspondence of $\mathrm{bil}(M \oplus N, R) \longleftrightarrow \mathrm{mat}_{r,s}(R)$ under the maps given in the claim (4.47). To do this let us also denote the basis representations $u = (u_1, \dots, u_s) = [x]_{\mathcal{M}}$ of $x \in M$ and $v = (v_1, \dots, v_r) = [y]_{\mathcal{N}}$ of $y \in N$.
Let us start with a matrix $B = (b_{i,j}) \in \mathrm{mat}_{r,s}(R)$ then we assign the map $b : M \oplus N \to R$ by letting $b(x,y) := \langle Bu \mid v \rangle$. Since both maps $x \mapsto u = [x]_{\mathcal{M}}$ and $u \mapsto \langle Bu \mid v \rangle$ are R-linear so is their composition $x \mapsto \langle Bu \mid v \rangle$. But this is the linearity of b in the first argument. Likewise $y \mapsto v = [y]_{\mathcal{N}}$ and $v \mapsto \langle Bu \mid v \rangle$ are R-linear such that $y \mapsto \langle Bu \mid v \rangle$ is R-linear which is the linearity of b in the second argument. Altogether b is bilinear and $B \mapsto b$ is well-defined. Now an easy computation reveals

$$\begin{aligned} b(x,y) &= \langle Bu \mid v \rangle \;=\; \sum_{i=1}^{r} [Bu]_i\, v_i \\ &= \sum_{i=1}^{r} \left(\sum_{j=1}^{s} b_{i,j} u_j \right) v_i \\ &= \sum_{i=1}^{r} \sum_{j=1}^{s} b_{i,j} u_j v_i \end{aligned}$$

In particular we find $b(m_j, n_i) = b_{i,j}$ (for any $i \in 1 \dots r$ and $j \in 1 \dots s$) such that the converse map $\mathrm{bil}(M \oplus N, R) \to \mathrm{mat}_{r,s}(R)$ truly matches $b \mapsto B$ again. Conversely if we start with a bilinear map $b : M \oplus N \to R$ and assign the matrix $B = (b_{i,j})$ where $b_{i,j} = b(m_j, n_i)$ we may continue the above computation to find

$$\langle Bu \mid v \rangle \;=\; \sum_{i=1}^{r} \sum_{j=1}^{s} b_{i,j} u_j v_i \;=\; \sum_{i=1}^{r} \sum_{j=1}^{s} b(m_j, n_i) u_j v_i$$

$$= \; b\left(\sum_{j=1}^{s} u_j m_j, \sum_{i=1}^{r} v_i n_i\right) \; = \; b(x,y)$$

That is we have also found the opposite direction $B \mapsto b$. Altogether we have established the mutually inverse maps $b \mapsto B$ and $B \mapsto b$ such that the correspondence is proved. It remains to show that (under the assumptions $M = N$ and $\mathcal{M} = \mathcal{N}$) b is symmetric if and only if B is such. Well, if b is symmetric, then $b_{i,j} = b(m_j, m_i) = b_(m_i, m_j) = b_{j,i}$ is obvious. But the converse implication requires only little effort: if B is symmetric, then

$$b(x,y) \; = \; \langle Bu \mid v \rangle \; = \; \langle u \mid B^* v \rangle \; = \; \langle u \mid Bv \rangle \; = \; \langle Bv \mid u \rangle \; = \; b(y,x)$$

□

Proof of (2.34):

- (a) $\implies$ (b): we have the assumption of (ACC) and need to show, that there is some maximal element $\mathfrak{a}^* \in \mathcal{A}^*$. That is there has to be some $\mathfrak{a}^* \in \mathcal{A}$ such that $(\mathfrak{a}^* \subseteq \mathfrak{a}) \implies (\mathfrak{a}^* = \mathfrak{a})$ for any $\mathfrak{a} \in \mathcal{A}$. Yet this statement is logically equivalent, to saying

 $$\exists\, \mathfrak{a}^* \in \mathcal{A} \;\; \forall\, \mathfrak{a} \in \mathcal{A} \; : \; \neg(\mathfrak{a}^* \subseteq \mathfrak{a}) \vee (\mathfrak{a}^* = \mathfrak{a})$$

 Suppose this was not the case - that is the negation of this statement was true. This is $\forall\, \mathfrak{a}^* \in \mathcal{A}\, \exists\, \mathfrak{a} \in \mathcal{A}$ such that $(\mathfrak{a}^* \subseteq \mathfrak{a}) \wedge (\mathfrak{a}^* \neq \mathfrak{a})$. And clearly this means nothing but

 $$\forall\, \mathfrak{a}^* \in \mathcal{A} \;\; \exists\, \mathfrak{a} \in \mathcal{A} \; : \; \mathfrak{a}^* \subset \mathfrak{a}$$

 Thus we could start by picking up any one $\mathfrak{a}_1 \in \mathcal{A}$ as $\mathfrak{a}^*$. And by the above property there would be some $\mathfrak{a}_2 \in \mathcal{A}$ such that $\mathfrak{a}_1 \subset \mathfrak{a}_2$. Continuing this way (using induction with $\mathfrak{a}^* := \mathfrak{a}_k$ and $\mathfrak{a}_{k+1} := \mathfrak{a}$) we could construct an infinitely ascending chain if ideals $\mathfrak{a}_1 \subset \mathfrak{a}_2 \subset \ldots \subset \mathfrak{a}_k \subset \mathfrak{a}_{k+1} \subset \ldots$ in contradiction to (ACC). Hence the assumption has to be false and this means, that (b) holds true.

- (b) $\implies$ (c): For any subset $H \subseteq I$ with $H \neq \emptyset$ let us denote the ideal $\mathfrak{a}_H \trianglelefteq_{\mathfrak{i}} R$ and the set $\mathcal{A}$ of these ideals that found on a finite subset $H \subseteq I$ to be:

 $$\begin{aligned} \mathfrak{a}_H \;\; &:= \;\; \sum_{i \in H} \mathfrak{a}_i \\ \mathcal{A} \;\; &:= \;\; \{\, \mathfrak{a}_H \mid H \subseteq I, 1 \leq \#H < \infty \,\} \end{aligned}$$

 Clearly $\mathcal{A} \neq \emptyset$ is nonempty, as $\mathfrak{a}_i \in \mathcal{A}$ for any $i \in I$. Hence by assumption (b) $\mathcal{A}$ has a maximal element $\mathfrak{a}^*$ and say $\mathfrak{a}^* = \mathfrak{a}_\Omega$ for some finite $\Omega \subseteq I$. Now consider any $i \in I$, then $\mathfrak{a}^* \subseteq \mathfrak{a}^* + \mathfrak{a}_i$. But as $\mathfrak{a}^* + \mathfrak{a}_i = \mathfrak{a}_H$ for the finite set $H = \Omega \cup \{\, i \,\} \subseteq I$ and $\mathfrak{a}^*$ is maximal, we get $\mathfrak{a}^* = \mathfrak{a}^* + \mathfrak{a}_i$ and in particular $\mathfrak{a}_i \subseteq \mathfrak{a}^*$. As this is true for any $i \in I$ we have

 $$\bigcup_{i \in \mathfrak{a}_i} \;\; \subseteq \;\; \mathfrak{a}^* \;\; = \;\; \mathfrak{a}_\Omega$$

 But as $\mathfrak{a}_\Omega$ is an ideal of R, the same is true for the ideal generated by the union of the $\mathfrak{a}_i$. And by

definition this is nothing but

$$\sum_{i\in I}\mathfrak{a}_i \quad\subseteq\quad \mathfrak{a}_\Omega \quad=\quad \sum_{i\in\Omega}\mathfrak{a}_i$$

- (c) $\Longrightarrow$ (d): Consider any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ and for any $a \in \mathfrak{a}$ we pick up the ideal $Ra \trianglelefteq_{\mathrm{i}} R$. Then

$$\sum_{a\in\mathfrak{a}} Ra \quad=\quad \mathfrak{a}$$

as any $Ra \subseteq \mathfrak{a}$ and conversely any $a \in \mathfrak{a}$ is contained in Ra. Also $\mathfrak{a} \neq \emptyset$, as $0 \in \mathfrak{a}$. Now by assumption (c) there is a finite subset $\{ a_1, \ldots, a_k \} \subseteq \mathfrak{a}$ such that

$$\sum_{a\in\mathfrak{a}} Ra \quad=\quad \sum_{i=1}^{k} Ra_i$$

and combining these equalities we have $\mathfrak{a} = Ra_1 + \cdots + Ra_k$. That is $\mathfrak{a}$ is finitely generated, which is claim (d) already.

- (d) $\Longrightarrow$ (a): consider an ascending chain $\mathfrak{a}_0 \subseteq \mathfrak{a}_1 \subseteq \ldots \subseteq \mathfrak{a}_k \subseteq \ldots$ of ideals in R. Then we define the set

$$\mathfrak{b} \qu:=\quad \bigcup_{k\in\mathbb{N}} \mathfrak{a}_k$$

As the $\mathfrak{a}_k$ have been a chain, we find that $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ is an ideal due to (2.4.(i)). And hence by assumption (d) there are finitely many elements $a_1, \ldots, a_n \in R$ generating $\mathfrak{b} = \langle a_1, \ldots, a_n \rangle_{\mathrm{i}}$. So by construction of $\mathfrak{b}$ for any $i \in 1 \ldots n$ (as $a_i \in \mathfrak{b}$) there is some $s(i) \in \mathbb{N}$ such that $a_i \in \mathfrak{a}_{s(i)}$. Now let $s := \max\{ s(1), \ldots, s(n) \}$. Then for any $i \in 1 \ldots n$ and any $t \geq s$ we get $a_i \in \mathfrak{a}_{s(i)} \subseteq \mathfrak{a}_s \subseteq \mathfrak{a}_t$. In particular

$$\mathfrak{b} \;=\; \langle a_1, \ldots, a_n \rangle_{\mathrm{i}} \quad\subseteq\quad \mathfrak{a}_t \quad\subseteq\quad \mathfrak{b}$$

Of course this means $\mathfrak{b} = \mathfrak{a}_t$ for any $t \geq s$. And this is just another way of saying that the chain of the $\mathfrak{a}_k$ stabilized at level s.

By now we have proved the equivalence of (a) to (d) in the definition of noetherian rings. And trivially we also have (d) $\Longrightarrow$ (e). These are the most important equivalences, it merely is a neat fact that (e) also implies (d). Though we will not use it we wish to present a proof (note that this is substantially more complicated than the important implications above).

- We will now prove (e) $\Longrightarrow$ (d) in several steps: We want to prove that *any* ideal of R is finitely generated. Thus let us take the set of all those ideals of R *not* being finitely generated:

$$\mathcal{Z} \qu:=\quad \{\, \mathfrak{a} \trianglelefteq_{\mathrm{i}} R \mid \mathfrak{a} \text{ is } \textit{not} \text{ finitely generated} \,\}$$

The idea of the proof will then be the following: suppose $\mathcal{Z} \neq \emptyset$, then by an application of Zorn's lemma, there is some maxmal element $\mathfrak{p} \in \mathcal{Z}^*$. In a second step we will then prove that any $\mathfrak{p} \in \mathcal{Z}^*$ is prime. So by assumption (d) $\mathfrak{p}$ is finitely generated. But because of $\mathfrak{p} \in \mathcal{Z}$ it also is not finitely generated. This can only mean $\mathcal{Z} = \emptyset$ and hence any ideal of R is finitely generated. Thus it remains to prove:

- $\mathcal{Z} \neq \emptyset \implies \mathcal{Z}^* \neq \emptyset$: thus consider a chain $(\mathfrak{a}_i)$ (where $i \in I$) in $\mathcal{Z}$. Then we denote the union

of this chain by

$$\mathfrak{b} \;=\; \bigcup_{i\in I} \mathfrak{a}_i$$

By (2.4.(i)) $\mathfrak{b} \trianglelefteq_{\mathfrak{i}} R$ is an ideal of R again. Now suppose $\mathfrak{b} \notin \mathcal{Z}$, then $\mathfrak{b}$ would be finitely generated, say $\mathfrak{b} = \langle b, \ldots, b_n\rangle_{\mathfrak{i}}$. By construction of $\mathfrak{b}$ for any $k \in 1 \ldots n$ (as $b_k \in \mathfrak{b}$) there is some $i(k) \in I$ such that $b_k \in \mathfrak{a}_{i(k)}$. And as the $\mathfrak{a}_i$ form a chain we may choose $i \in I$ such that $\mathfrak{a}_i := \max\Big\{ \mathfrak{a}_{i(1)}, \ldots, \mathfrak{a}_{i(n)} \Big\}$. Thereby $\mathfrak{b} = \langle b_1, \ldots, b_n\rangle_{\mathfrak{i}} \subseteq \mathfrak{a}_i \subseteq \mathfrak{b}$. That is $\mathfrak{a}_i = \langle b_1, \ldots, b_n\rangle_{\mathfrak{i}}$ would be finitely generated in contradiction to $\mathfrak{a}_i \in \mathcal{Z}$. Thus we have $\mathfrak{b} \in \mathcal{Z}$ again and hence $\mathfrak{b}$ is an upper bound of $(\mathfrak{a}_i)$. Now - as any chain has an upper bound, by the lemma of Zorn - there is some maximal element $\mathfrak{p} \in \mathcal{Z}^*$.

- $\mathfrak{p} \in \mathcal{Z}^* \implies \mathfrak{p}$ prime: First note thet $\mathfrak{p} \neq R$, as $R = 1R$ is finitely generated. Now suppose $\mathfrak{p}$ was not prime, then there would be some $f, g \in R$ such that $f \notin \mathfrak{p}$, $g \notin \mathfrak{p}$ but $fg \in \mathfrak{p}$. Now let $\mathfrak{a} := \mathfrak{p} + fR$, as $f \notin \mathfrak{p}$ we find $\mathfrak{p} \subset \mathfrak{a}$. And as $\mathfrak{p}$ is a maximal element of $\mathcal{Z}$ this means that $\mathfrak{a}$ is finitely generated, say $\mathfrak{a} = \langle a_1, \ldots, a_k\rangle_{\mathfrak{i}}$. As the $a_i \in \mathfrak{a} = \mathfrak{p} + fR$ there are some $p_i \in \mathfrak{p}$ and $b_i \in R$ such that $a_i = p_i + fb_i$. Therefore

$$\mathfrak{a} \;=\; \langle p_1, \ldots, p_k, f\rangle_{\mathfrak{i}} \;=\; p_1R + \cdots + p_kR + fR$$

The inclusion " $\supseteq$ " is clear, as $p_i \in \mathfrak{p} \subseteq \mathfrak{a}$ and $f \in \mathfrak{a}$. Conversely consider $x \in \mathfrak{a}$, that is there are some $x_i \in R$ such that $x = \sum_i x_i a_i = \sum_i x_i p_i + f \sum_i x_i b_i \in p_1R + \cdots + p_kR + fR$. Next we note that

$$\mathfrak{p} \;=\; f(\mathfrak{p} : f) + p_1R + \cdots + p_kR$$

where $f(\mathfrak{p} : f) = (fR)\,(\mathfrak{p} : f) = \{\, fb \mid b \in \mathfrak{p} : f \,\} \trianglelefteq_{\mathfrak{i}} R$. The inclusion " $\supseteq$ " is easy: $p_i \in \mathfrak{p}$ is true by definition. Thus consider any element $x \in f(\mathfrak{p} : f)$. That is $x = fb$ for some $b \in \mathfrak{p} : f = \{\, b \in R \mid fb \in \mathfrak{p} \,\}$. In particular $x = bf \in \mathfrak{p}$, too. For the converse inclusion we are given any $q \in \mathfrak{p} \subseteq \mathfrak{a}$. That is there are some $x_i \in R$ and $y \in R$ such that $q = x_1p_1 + \cdots + x_kp_k + yf$. As q and all the p_i are contained in $\mathfrak{p}$ this implies $yf \in \mathfrak{p}$ and thereby $y \in \mathfrak{p} : f$. Thus $yf \in f(\mathfrak{p} : f)$ and hence $q \in p_1R + \cdots + p_kR + f(\mathfrak{p} : f)$. Finally we prove

$$\mathfrak{p} : a \;\notin\; \mathcal{Z}$$

Clearly we get $\mathfrak{p} \subseteq \mathfrak{p} : a$ and $b \in \mathfrak{p} : a$ (because of $ab \in \mathfrak{p}$). But $b \notin \mathfrak{p}$ and hence $\mathfrak{p} \subset \mathfrak{p} : a$. But by the maximality of $\mathfrak{p}$ in $\mathcal{Z}$ this means $\mathfrak{p} : a \notin \mathcal{Z}$. Thus $\mathfrak{p} : a$ is finitely generated and hence $a(\mathfrak{p} : a)$ is finitely generated, too. But as the sum of finitely generated ideals is finitely generated by (1.59) this means that $\mathfrak{p} = a(\mathfrak{p} : a) + p_1R + \cdots + p_k$ is finitely generated, too, in contradiction to $\mathfrak{p} \in \mathcal{Z}$. Thus the assumption of $\mathfrak{p}$ not being prime is false.

□

Proof of (2.40):

(i) We will only prove the noetherian case - the arinian case is an analogous argument involving descending (instead of ascending) chains of ideals. Thus consider an ascending chain of ideals in $R/\mathfrak{a}$

$$\mathfrak{u}_0 \;\subseteq\; \mathfrak{u}_1 \;\subseteq\; \ldots \;\subseteq\; \mathfrak{u}_k \;\subseteq\; \ldots \;\trianglelefteq_{\mathfrak{i}}\; R\Big/_{\mathfrak{a}}$$

By the correspondence theorem (1.66) the ideals $\mathfrak{u}_k$ are of the form $\mathfrak{u}_k = \mathfrak{b}_k/\mathfrak{a}$ for sufficient ideals $\mathfrak{b}_k := \varrho^{-1}(\mathfrak{u}_k) \trianglelefteq_{\mathrm{i}} R$. Now suppose $b \in \mathfrak{b}_k$ then $b + \mathfrak{a} \in \mathfrak{u}_k \subseteq \mathfrak{u}_{k+1} = \mathfrak{b}_{k+1}/\mathfrak{a}$ and hence $b \in \mathfrak{b}_{k+1}$ again. Thus we have found an ascending chain of ideals in R

$$\mathfrak{b}_0 \subseteq \mathfrak{b}_1 \subseteq \ldots \subseteq \mathfrak{b}_k \subseteq \ldots \trianglelefteq_{\mathrm{i}} R$$

As R is noetherian this chain has to be eventually constant, that is there is some $s \in \mathbb{N}$ such that for any $i \in \mathbb{N}$ we get $\mathfrak{b}_{s+i} = \mathfrak{b}_s$. But this clearly implies $\mathfrak{u}_{s+i} = \mathfrak{u}_s$ as well and hence $R/\mathfrak{a}$ is noetherian again.

(ii) If $\varphi : R \twoheadrightarrow S$ is a surjective homomorphism, then by the first isomorphism theorem (1.83) we get $R/\mathrm{kn}(\varphi) \cong_{\mathrm{r}} S$. But by assumption R is $\star$ and hence $R/\mathrm{kn}(\varphi)$ is $\star$, too, due to (i). And because of this isomorphy we find that S thereby is $\star$, as well [this is clear by transferring a chain of ideals from S to $R/\mathrm{kn}(\varphi)$ and returning to S].

(iii) First suppose that $R \oplus S$ is $\star$. Trivially we have the following surjective ring homomorphisms $R \oplus S \twoheadrightarrow R : (a,b) \mapsto a$ and $R \oplus S \twoheadrightarrow R : (a,b) \mapsto b$. Thus both R and S are $\star$ due to (ii). Conversely suppose both R and S are noetherian. We will prove that this implies $R \oplus S$ to be noetherian again (the proof in the artinian case is completely analogous). Thus consider an ascending chain of ideals of $R \oplus S$

$$\mathfrak{u}_0 \subseteq \mathfrak{u}_1 \subseteq \ldots \subseteq \mathfrak{u}_k \subseteq \ldots \trianglelefteq_{\mathrm{i}} R \oplus S$$

Clearly $R \oplus 0$ and $0 \oplus S \trianglelefteq_{\mathrm{i}} R \oplus S$ are ideals of $R \oplus S$, too. Thus we obtain ideals $\mathfrak{a}_k := \mathfrak{u}_k \cap (R \oplus 0)$ and $\mathfrak{b}_k := \mathfrak{u}_k \cap (0 \oplus S) \trianglelefteq_{\mathrm{i}} R \oplus S$ be intersection. And for these we get

$$\mathfrak{u}_k = \mathfrak{a}_k + \mathfrak{b}_k$$

The inclusion " $\supseteq$ " is clear, as $\mathfrak{a}_k$, $\mathfrak{b}_k \subseteq \mathfrak{u}_k$. For the converse inclusion "$\subseteq$" we are given some $(a,b) \in \mathfrak{u}_k$. As $\mathfrak{u}_k$ is an ideal we find $(a,0) = (1,0)(a,b)$ and $(0,b) = (0,1)(a,b) \in \mathfrak{u}_k$. And as also $(a,0) \in R \oplus 0$ and $(0,b) \in 0 \oplus S$ this yields $(a,b) = (a,0) + (0,b) \in \mathfrak{a}_k + \mathfrak{b}_k$. But as $\mathfrak{a}_k$ is an ideal of $R \oplus S$ contained in $R \oplus 0$ it in particular is an ideal of $\mathfrak{a}_k \trianglelefteq_{\mathrm{i}} R \oplus 0$. But clearly R and $R \oplus 0$ are isomorphic under $R \cong_{\mathrm{r}} R \oplus 0 : a \mapsto (a,0)$. Thus $\mathfrak{a}_k$ corresponds to the following ideal $\mathfrak{a}_k^\circ := \{\, a \in R \mid (a,0) \in \mathfrak{a}_k \,\} \trianglelefteq_{\mathrm{i}} R$. And thus we have found an ascending chain of ideals in R

$$\mathfrak{a}_0^\circ \subseteq \mathfrak{a}_1^\circ \subseteq \ldots \subseteq \mathfrak{a}_k^\circ \subseteq \ldots \trianglelefteq_{\mathrm{i}} R$$

Yet as R was assumed to be noetherian there is some $p \in \mathbb{N}$ such that for any $i \in \mathbb{N}$ we get $\mathfrak{a}_{p+i}^\circ = \mathfrak{a}_p^\circ$. And returning to $R \oplus 0$ (via $\mathfrak{a}_k = \{\, (a,0) \mid a \in \mathfrak{a}_k^\circ \,\}$) we find that $\mathfrak{a}_{p+i} = \mathfrak{a}_p$ as well. With the same argument for the $\mathfrak{b}_k$ we find some $q \in \mathbb{N}$ such that for any $i \in \mathbb{N}$ we get $\mathfrak{b}_{q+i} = \mathfrak{b}_q$. Now let $s := \max\{\, p, q \,\}$ then it is clear that for any $i \in \mathbb{N}$ we get

$$\mathfrak{u}_{s+i} = \mathfrak{a}_{s+i} + \mathfrak{b}_{s+i} = \mathfrak{a}_s + \mathfrak{b}_s = \mathfrak{u}_s$$

that is the chain of the $\mathfrak{u}_k$ has been eventually constant. And this means nothin but $R \oplus S$ being noetherian again.

□

Proof of (2.42):
This proof requires some working knowledge of polynomials as it is presented in sections 7.2 and 7.3. Yet as the techniques used in this proof are fairly easy to see we chose to place the proof here already. In case you encounter problems with the arguements herein refer to these sections first.

(1) In a first step let us consider the case where $S = R[t]$ is the polynomial ring over R. Thus consider an ideal $\mathfrak{u} \trianglelefteq_{\mathfrak{i}} S$, then we want to verify that $\mathfrak{u}$ is finitely generated. The case $\mathfrak{u} = 0$ is clear, thus we assume $\mathfrak{u} \neq 0$. Then for any $k \in \mathbb{N}$ we denote

$$\mathfrak{a}_k \;:=\; \{\, \mathrm{lc}(f) \mid f \in \mathfrak{u},\ \deg(f) = k \,\} \cup \{0\}$$

where $\mathrm{lc}(f) := f[\deg(f)]$ denotes the *leading coefficient* of f. We will first prove that $\mathfrak{a}_k \trianglelefteq_{\mathfrak{i}} R$ is an ideal of R: $0 \in \mathfrak{a}_k$ is clear by construction. Thus suppose $a, b \in \mathfrak{a}_k$ say $a = \mathrm{lc}(f)$ and $b = \mathrm{lc}(g)$. As both f and g are of degree k we get $(f+g)[k] = f[k] + g[k] = \mathrm{lc}(f) + \mathrm{lc}(g) = a + b$. Thus if $a + b = 0$ then $a + b \in \mathfrak{a}_k$ is clear. And else, if $a + b \neq 0$ then $f + g$ is of degree k, too and $\mathrm{lc}(f+g) = (f+g)[k] = a + b$. And as $f + g \in \mathfrak{u}$ again we find $a + b \in \mathfrak{a}_k$ in both cases. Now let $r \in R$ be any element, if $ra = 0$ then $ra \in \mathfrak{a}_k$ is trivial again. And else $rf : k \mapsto rf[k]$ is of degree k again and satisfies $\mathrm{lc}(rf) = (rf)[k] = r(f[k]) = r\mathrm{lc}(f) = ra$. And as also $rf \in \mathfrak{u}$ we again found $ra \in \mathfrak{a}_k$ in both cases. Altogether $\mathfrak{a}_k \trianglelefteq_{\mathfrak{i}} R$ is an ideal. Next we will also prove the containment $\mathfrak{a}_k \subseteq \mathfrak{a}_{k+1}$. That is we consider some $a = \mathrm{lc}(f) \in \mathfrak{a}_k$ again. As $f \in \mathfrak{u}$ we also have $tf : k \mapsto f[k-1] \in \mathfrak{u}$. Obviously $\deg(tf) = \deg(f) + 1 = k + 1$ and $\mathrm{lc}(tf) = f[k+1] = f[k] = a$. Thus we have found $a = \mathrm{lc}(tf) \in \mathfrak{a}_{k+1}$. Altogether we have found the following ascending chain of ideals of R

$$\mathfrak{a}_0 \;\subseteq\; \mathfrak{a}_1 \;\subseteq\; \ldots \;\subseteq\; \mathfrak{a}_k \;\subseteq\; \ldots \;\trianglelefteq_{\mathfrak{i}}\; R$$

- As R is noetherian this chain has to be eventually constant, that is there is some $s \in \mathbb{N}$ such that for any $i \in \mathbb{N}$ we get $\mathfrak{a}_{s+i} = \mathfrak{a}_s$. And furthermore any $\mathfrak{a}_k$ is finitely generated (as R is noetherian). As we may choose generators of $\mathfrak{a}_k$ we do so

$$\mathfrak{a}_k \;=\; \langle a_{k,1}, \ldots, a_{k,n(k)} \rangle_{\mathfrak{i}}$$

and pick up polynomials $f_{k,i} \in \mathfrak{u}$ of degree $\deg(f_{k,i}) = k$ such that $\mathrm{lc}(f_{k,i}) = a_{k,i}$. Then we define the following ideal of S

$$\mathfrak{w} \;:=\; \langle f_{k,1} \mid k \in 0 \ldots s,\ i \in 1 \ldots n(k) \rangle_{\mathfrak{i}}$$

- For the first step it remains to prove that $\mathfrak{u} = \mathfrak{w}$. Then $\mathfrak{u}$ is finitely generated, as we have given a list of generators explictly. The inclusion $\mathfrak{w} \subseteq \mathfrak{u}$ is clear, as any $f_{i,k} \in \mathfrak{u}$. For the converse inclusion we start with some $f \in \mathfrak{u}$ and need to show $f \in \mathfrak{w}$. This will be done by induction on the degree $k := \deg(f)$ of f. The case $f = 0$ is clear. If $\deg(f) = k = 0$ then $f \in R$ is constant, that is $f = \mathrm{lc}(f) \in \mathfrak{a}_0 = \langle a_{0,1}, \ldots, a_{0,n(0)} \rangle_{\mathfrak{i}} \subseteq \mathfrak{w}$. Thus for the induction step we suppose $k \geq 1$ and let $a := \mathrm{lc}(f) = f[k]$. If $k \leq s$ then $a \in \mathfrak{a}_k = \langle a_{k,1}, \ldots, a_{k,n(k)} \rangle_{\mathfrak{i}}$. That is there are some $b_i \in R$

such that $a = \sum_i a_{k,i} b_i$. Now let us define the polynomial

$$g \;:=\; \sum_{i=1}^{n(k)} b_i f_{k,i} \;\in\; \mathfrak{w}$$

Then it is clear that $\mathrm{lc}(g) = \sum_i b_i \mathrm{lc}(f_{i,k}) = a = \mathrm{lc}(f)$ and hence $\deg(f-g) < k$. Thus by the induction hypothesis we get $d := f - g \in \mathfrak{w}$ again and hence $f = d + g \in \mathfrak{w}$, too. It remains to check the case $k > s$. Yet this can be dealt with using a similar argument. As $k \geq s$ we have $a \in \mathfrak{a}_k = \mathfrak{a}_s$. That is $a = \sum_i a_{k,i} b_i$ for sufficient $b_i \in R$. This time

$$g \;:=\; \sum_{i=1}^{n(s)} b_i t^{k-s} f_{k,i} \;\in\; \mathfrak{w}$$

Then $\mathrm{lc}(g) = \sum_i b_i \mathrm{lc}(f_{i,k}) = a = \mathrm{lc}(f)$ again and as before this is $\deg(f-g) < k$. By induction hypothesis again $d := f - g \in \mathfrak{w}$ and hence $f = d + g \in \mathfrak{w}$. Thus we have finished the case $S = R[t]$.

(2) As a second case let us regard $S = R[t_1, \ldots, n]$ the polynomial ring in finitely many variables. Again we want to prove that S in noetherian, and this time we use induction on the number n of variables. The case $n = 1$ has just been treated in (1). Thus consider $R[t_1, \ldots, t_n, t_{n+1}]$. Then we use the isomorphy

$$R[t_1, \ldots, t_n, t_{n+1}] \;\cong_{\mathrm{r}}\; R[t_1, \ldots, t_n][t_{n+1}]$$
$$\sum_\alpha f[\alpha] t^\alpha \;\mapsto\; \sum_{i=0}^{\infty} \left(\sum_{\alpha_{n+1}=i} f[\alpha] t_1^{\alpha_1} \ldots t_n^{\alpha_n} \right) t_{n+1}^i$$

By induction hypothesis $R[t_1, \ldots, t_n]$ is noetherian already. And by (1) this implies $R[t_1, \ldots, t_n][t_{n+1}]$ to be noetherian, too. And using the above isomorphy we finally find that $R[t_1, \ldots, t_n, t_{n+1}]$ is noetherian.

(3) We now easily derive the the general claim: let S be finitely generated over R. That is there are finitely many $e_1, \ldots, e_n \in S$ such that $S = R[e_1, \ldots, e_n]$. Then we trivially have a surjective homomoprphism $R[t_1, \ldots, t_n] \twoheadrightarrow S : f \mapsto f(e_1, \ldots, e_n)$ form the polynomial ring onto S. And by (2.40.(iii)) this implies that S is noetherian, too.

□

Proof of (2.47):
Let us denote the prime ring of R by $P := \langle \emptyset \rangle_{\mathrm{r}}$. This is the image of the uniquely determined ring-homomorphism from $\mathbb{Z}$ to R (induced by $1 \mapsto 1$). That is $P = \mathrm{im}(\mathbb{Z} \to R)$ and in particular P is noetherian by (2.40.(ii)). Let us now denote the set of finite, non-empty subsets of R by I

$$I \;:=\; \{\, i \subseteq R \mid i \neq \emptyset,\, \#i < \infty \,\}$$

And for any $i \in I$ let us denote $R_i := P[i]$ the P-subalgebra of R generated by i. Then by the Hilbert's basis theorem R_i is noetherian as well. Given any $a \in R$ we clearly have $i := \{a\} \in I$ and $a \in R_i$. In particular the R_i cover R. And given any two $i, j \in I$ we have $k := i \cup j \in I$, too. We now claim that $R_i \cup R_j \subseteq R_i$: thus suppose $i = \{i_1, \ldots, i_n\}$ and let $a = f(i_1, \ldots, i_n)$ for some

polynomial $f \in P[t_1,\ldots,t_n]$. Then it is clear that $a = g(i_1,\ldots,i_n,j_1,\ldots,j_m) \in P[i \cup j] = R_k$ if we only let $g(t_1,\ldots,t_n,t_{n+1},\ldots,t_{n+m}) := f(t_1,\ldots,t_n) \in P[t_1,\ldots,t_{n+m}]$. Thus we have seen $R_i \subseteq R_k$ and $R_j \subseteq R_k$ can be proved in complete analogy. □

Proof of (2.45):

(i) This has been proved in (2.34) as implication (a) $\implies$ (b) already. The reader is asked to refer to page 1031 for the proof.

(iii) Just let $\mathcal{P} := \{\, \mathfrak{b} \in \operatorname{Spec}(R) \mid \mathfrak{p} \subseteq \mathfrak{b} \subset \mathfrak{q} \,\}$. Then $\mathcal{P} \neq \emptyset$ is non-empty, as $\mathfrak{p} \in \mathcal{P}$. But as we have seen (i) this already implies that there is some maximal element $\mathfrak{q}_\circ \in \mathcal{P}^*$.

(iv) For any ideal $R \neq \mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ let us denote $\mathbb{V}(\mathfrak{a}) := \{\, \mathfrak{p} \in \operatorname{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\}$ and $n(\mathfrak{a}) := \#\mathbb{V}(\mathfrak{a})_* \in \mathbb{N} \cup \{\infty\}$. That is $n(\mathfrak{a})$ is the number of minimal prime ideals lying over $\mathfrak{a}$. By (2.18.(iii)) we know $1 \leq n(\mathfrak{a})$. Now let

$$\mathcal{A} \;:=\; \{\, \mathfrak{a} \trianglelefteq_{\mathrm{i}} R \mid n(\mathfrak{a}) = \infty \,\}$$

be the set of all ideals having infinitely many minimal primes lying over it. We want to show that $\mathcal{A} = \emptyset$. Hence assume $\mathcal{A} \neq \emptyset$, then - by (i), as R is noetherian - we may choose some maximal ideal $\mathfrak{u} \in \mathcal{A}^*$ in $\mathcal{A}$. Clearly $\mathfrak{u}$ cannot be prime: if it was then $\mathfrak{u}$ would be contained in precisely one minimal prime - namely $\mathfrak{u}$ itself, that is $\mathbb{V}(\mathfrak{u})_* = \{\mathfrak{u}\}$. In particular we had $n(\mathfrak{u}) = 1 < \infty$ which contradicts $\mathfrak{u} \in \mathcal{A}$. Now, as $\mathfrak{u}$ is *not* prime, there are some $a, b \in R$ such that $ab \in \mathfrak{u}$ but $a, b \notin \mathfrak{u}$. Then we define the respective ideals

$$\mathfrak{a} \;:=\; \mathfrak{u} + aR \quad \text{and} \quad \mathfrak{b} \;:=\; \mathfrak{u} + bR$$

As $a \notin \mathfrak{u}$ we have $\mathfrak{u} \subset \mathfrak{a}$ and hence $\mathfrak{a} \notin \mathcal{A}$ due to the maximality of $\mathfrak{u}$. Likewise $\mathfrak{b} \notin \mathcal{A}$ and this means that $n(\mathfrak{a}), n(\mathfrak{b}) < \infty$ are finite. But we will now prove

$$\mathbb{V}(\mathfrak{u})_* \;\subseteq\; \mathbb{V}(\mathfrak{a})_* \cup \mathbb{V}(\mathfrak{b})_*$$

To see this let $\mathfrak{p} \in \mathbb{V}(\mathfrak{u})_*$ be a minimal prime ideal over $\mathfrak{u}$. If $a \in \mathfrak{p}$ then $\mathfrak{a} \subseteq \mathfrak{p}$. Else suppose $a \notin \mathfrak{p}$ then $ab \in \mathfrak{u} \subseteq \mathfrak{p}$ implies $b \in \mathfrak{p}$, as $\mathfrak{p}$ is prime. And thereby we get $\mathfrak{b} \subseteq \mathfrak{p}$. In any case $\mathfrak{p}$ lies over one of the ideals $\mathfrak{a}$ or $\mathfrak{b}$, say $\mathfrak{a} \subseteq \mathfrak{p}$ (w.l.o.g.). If now $\mathfrak{q} \in \mathbb{V}(\mathfrak{a})$ then in particular we get $\mathfrak{q} \in \mathbb{V}(\mathfrak{u})$. Thus if $\mathfrak{q} \subseteq \mathfrak{p}$ then the minimality of $\mathfrak{p}$ over $\mathfrak{u}$ implies $\mathfrak{q} = \mathfrak{p}$. That is $\mathfrak{p}$ is a minimal element of $\mathbb{V}(\mathfrak{a})$ and hence the inclusion. As both $\mathbb{V}(\mathfrak{a})_*$ and $\mathbb{V}(\mathfrak{b})_* < \infty$ are finite, $\mathbb{V}(\mathfrak{u})_* < \infty$ would have to be finite, too. But this contradicts $\mathfrak{u} \in \mathcal{A}$ again, so the assumption $\mathcal{A} \neq \emptyset$ has to be abandoned. That is any ideal $\mathfrak{a}$ of R only has finitely many prime ideals lying over it.

(ii) Consider a set of prime ideals $\mathcal{P} \neq \emptyset$ of the noetherian ring R. It has already been shown in (2.34) that $\mathcal{P}^* \neq \emptyset$ contains maximal elements. We will now prove that $\mathcal{P}_* \neq \emptyset$ contains a minimal element, as well. Suppose this was untrue, then we start with any $\mathfrak{p} = \mathfrak{p}_0 \in \mathcal{P}$. As $\mathfrak{p}_0$ is not minimal in $\mathcal{P}$, there is some $\mathfrak{p}_1$ such that $\mathfrak{p}_0 \supset \mathfrak{p}_1$. Again $\mathfrak{p}_1$ is not minimal in $\mathcal{P}$, such that we may choose some $\mathfrak{p}_2 \in \mathcal{P}$ such that $\mathfrak{p}_1 \supset \mathfrak{p}_2$. Continuing that way we find an infinite, strictly descending chain of prime ideals

$$\mathfrak{p} \;=\; \mathfrak{p}_0 \;\supset\; \mathfrak{p}_1 \;\supset\; \mathfrak{p}_2 \;\supset\; \ldots \;\supset\; \mathfrak{p}_k \;\supset\; \ldots$$

This means that $\mathfrak{p}$ is a prime ideal of infinite height $\operatorname{height}(\mathfrak{p}) = \infty$. But in a noetherian ring we have Krull's height theorem (8.80.(ii)). And this states that $\operatorname{height}(\mathfrak{p}) \leq \operatorname{rank}(\mathfrak{p}) < \infty$. Hereby the rank is finite, as any ideal $\mathfrak{p}$ in a noetherian ring is finitely generated.

□

Proof of (2.48):
We start with the equivalences for $a \mid b$. Hereby (a) $\implies$ (c) is clear: $b \in aR = \{ ah \mid h \in R \}$ yields $b = ah$ for some $h \in R$. (c) $\implies$ (b): consider $f \in bR$, that is $f = bg$ for some $g \in R$. But as $b = ah$ this yields $f = ahg \in aR$. (b) $\implies$ (a): as $b \in bR \subseteq aR$ we have $b \in aR$.
We also have to check the equivalences for $a \approx b$ - recall that now R is an integral domain. (a) $\implies$ (b): if $aR = bR$ then in particular $aR \subseteq bR$ and hence $b \mid a$. Likewise we get $a \mid b$. (b) $\implies$ (c): Suppose $b = \alpha a$ and $a = \beta b$. If $b = 0$ then $a = \beta b = \beta \cdot 0 = 0$, as well. And hence we may choose $\alpha := 1$. Thus we continue with $b \neq 0$. Then $b = \alpha a = \alpha\beta b$. And as R is an integral domain and $b \neq 0$ we may divide by b and thereby obtain $1 = \alpha\beta$. That is $\alpha \in R^*$ and $b = \alpha a$ as claimed. (c) $\implies$ (a): As $b = \alpha a$ we get $bR \subseteq aR$. And from $a = \alpha^{-1} b$ we get $aR \subseteq bR$. □

Proof of (2.51):

(i) By definition of 1 we have $1 \cdot b = b$ and hence $1 \mid b$, likewise we have $a \cdot 0 = 0$ and hence $a \mid 0$ by (1.41). Now $ah = ab$ for $h := b$ and hence $a \mid ab$ is trivial again.

(i) Next suppose $b = 0$, then $b = 0 \cdot 1$ and hence $0 \mid b$. Conversely suppose $0 \mid b$, that is there is some $h \in R$ such that $0 = 0 \cdot h = b$. Then we have just proved $0 = b$, as well. If $a \in R^*$ then $1 = aa^{-1}$ and hence $a \mid 1$. Conversely suppose $a \mid 1$, that is there is some $h \in R$ such that $ah = 1$. As R is commutative this also is $ha = 1$ and hence $a \in R^*$. Finally let $a \mid b$, that is $ah = b$ for some $h \in R$ again. In particular this yields $(ac)h = (ah)c = bc$ and hence $ac \mid bc$.

(ii) Now suppose $u \in R$ is a non-zero divisor, by (i) we only have to show the implication " $\Longleftarrow$ ". Thus let $(au)h = bu$ for some $h \in R$, then $(ah - b)u = (au)h - bu = 0$. But as u is a non-zero divisor this can only happen if $ah - b = 0$ and this already is $a \mid b$.

(iii) First of all $a \mid a$ is clear by $a \cdot 1 = a$. If now $a \mid b$ and $b \mid c$ (say $ag = b$ and $bh = c$) then we get $a \mid c$ from $a(gh) = (ag)h = bh = c$. And that $a \mid b$ and $b \mid a$ implies $a \approx b$ is true by definition (2.48).

(iv) As we have seen in (2.48) $a \approx b$ is equivalent, to $aR = bR$. And from this it is clear that $\approx$ is reflexive, symmetric and transitive (i.e. an equivalence relation). Thus it only remains to observe that

$$[a] \;=\; \{\, b \in R \mid a \approx b \,\} \;=\; \{\, \alpha a \mid \alpha \in R^* \,\} \;=\; aR^*$$

□

Proof of (2.58):

(i) The statement is clear by induction on the number k of elements involved: if $k = 1$ then $p \mid a_1$ is just the assumption. Thus consider $k+1$ elements and let $a := a_1 \ldots a_k$ and $b := a_{k+1}$. Then by assumption we have $p \mid ab$ and (as p is prime) hence $p \mid a$ or $p \mid b$. If $p \mid b$ then we are done (with $i = k+1$). And if $p \mid a$ then by induction hypothesis we find some $i \in 1 \ldots k$ such that $p \mid a_i$. Altogether $p \mid a_i$ for some $i \in 1 \ldots k+1$.

(ii) If $p \in R$ is prime then $p \neq 0$ by definition. And as also $p \notin R^*$ we have $pR \neq R$, as well. Now $ab \in pR$ translates into $p \mid ab$ and hence $p \mid a$ or $p \mid b$. But this again is $a \in pR$ or $b \in pR$. That is we have proved that pR is prime. Conversely suppose $p \neq 0$ and that pR is a prime ideal. As $pR \neq R$ we have $p \notin R^*$. And as we also assumed $p \neq 0$ this means $p \in R^\bullet$. If we are now given $a, b \in R$ with $p \mid ab$, then $ab \in pR$ and hence $a \in pR$ or $b \in pR$, as pR is prime. Thus we find $p \mid a$ or $p \mid b$ again, and altogether p is prime.

(iii) "p irreducible $\implies$ αp irreducible": suppose $\alpha p = ab$ for some $a, b \in R$. As α is a unit this yields $p = (\alpha^{-1}a)b$ and as p is irreducible hence $\alpha^{-1}a \in R^*$ or $b \in R^*$. But $\alpha^{-1}a \in R^*$ already implies $a \in R^*$ (with inverse $a^{-1} = \alpha^{-1}(\alpha^{-1}a)^{-1}$). Conversely if αp is irreducible then $p = \alpha^{-1}\alpha p$ is irreducible, too by what we have just proved.

(iii) "p prime $\implies$ αp prime": suppose $\alpha p \mid ab$ for some $a, b \in R$. As α is a unit this yields $p \mid (\alpha^{-1}a)b$ and as p is prime we hence get $p \mid \alpha^{-1}a$ or $p \mid b$. From $p \mid \alpha^{-1}a$ we get $\alpha p \mid a$ and $p \mid b$ implies $p \mid \alpha^{-1}p$ which also implies $\alpha p \mid b$. Thus we have proved, that αp is prime too. Conversely if αp is prime then $p = \alpha^{-1}\alpha p$ is prime, too by what we have just proved.

(iv) Now let R be an integral domain, $p \in R$ be prime and suppose $p = ab$ for some $a, b \in R$. In particular $p \mid ab$ and hence $p \mid a$ or $p \mid b$. W.l.o.g. let us assume $p \mid b$, that is $ph = b$ for some $h \in R$. Then we get $p = ab = aph$ and hence $p(1 - ah) = 0$. Now as $p \neq 0$ this implies $ah = 1$, that is $a \in R^*$ is a unit of R. Thereby we have verified, that p truly is irreducible.

(v) Let $f := ab$, then it is clear that $a \mid f$ and hence $fR \subseteq aR$. And as both a and $b \neq 0$ are non-zero, so is f (as R is an integral domain). Now suppose we had $a \in fR$, that is $a = fg$ for some $g \in R$. Then we compute $a = fg = abg$. And as $a \neq 0$ this means $1 = bg$. In particular $b \in R^*$ is a unit, in contradiction to $b \in R^\bullet$. Hence $a \in aR \setminus fR$ and this yields the claim $fR \subset aR$.

(vi) If $f \approx p$ then $p = \alpha f$ for some $\alpha \in R^*$ and in particular this means $f \mid p$. Conversely suppose $f \mid p$, that is there is some $a \in R$ such that $p = af$, in particular $p \mid af$. As p is prime we hence get $p \mid a$ or $p \mid f$. If $p \mid f$ then we already have $f \approx p$, as we also have $f \mid p$. So suppose we had $p \mid a$. This would mean $a = bp$ for some $b \in R$ and hence $p = af = bpf$. As R is an integral domain, we conclude $1 = bf$ such that $f \in R^*$. But as $f \notin R^*$ this is false.

(vii) As $d \mid a$ and $d \mid b$ there are some elements $\alpha = a/d$ and $\beta = b/d \in R$ such that $a = \alpha d$ and $b = \beta d$. Now consider some $\delta \in R$ such that $\delta \mid \alpha$ and $\delta \mid \beta$. That is $\alpha = u\delta$ and $\beta = v\delta$ for some u and $v \in R$. Then $a = \alpha d = u\delta d$ and $b = \beta d = v\delta d$ such that $\delta d \mid a$ and $\delta d \mid b$. Now since $d \in \gcd\{a, b\}$ is a greatest common divisor of a and b, we get $\delta d \mid d$. However it is also clear that $d \mid \delta d$ which implies $d \approx \delta d$. Now as R is an integral domain this yields $\delta \in R^*$. But as $\delta \in R$ only needed to satisfy $\delta \mid \alpha$ and $\delta \mid \beta$ this means $1 \in \gcd\{\alpha, \beta\}$.

(viii) Clearly we have $R^* \subseteq D$, as $k = 0$ is allowed. And if $c = \alpha p_1 \dots p_k$ and $d = \beta q_1 \dots q_l \in D$ it is clear that $cd = (\alpha\beta)(p_1 \dots p_k q_1 \dots q_l) \in D$ again. Thus it remains to show the implication $cd \in D$ $\implies$ $c \in D$ (due to the symmetry of the statement it also follows that $d \in D$). Thus consider any $c, d \in R$ such that $cd = \alpha p_1 \dots p_k \in D$. We will prove the claim by induction on k - that is we will verify

$$\forall\, c, d \in R \,:\, cd = \alpha p_1 \dots p_k \in D \quad \implies \quad c \in D$$

for any $k \in \mathbb{N}$. The case $k = 0$ is trivial, since $cd = \alpha \in R^*$ implies $c \in R^* \subseteq D$. Thus regard $k \geq 1$. We let $I := \{i \in 1 \dots k \mid p_i \mid d\}$. (1) If there is some $i \in I$ then $p_i \mid b$. W.l.o.g. we may assume $i = k$. That is there is some $h \in R$ such that $d = hp_k$. Then

$$\alpha p_1 \dots p_k \;=\; cd \;=\; chp_k$$

As R is an integral domain and $p_k \neq 0$ we may divide by p_k to find $ch = \alpha p_1 \dots p_{k-1} \in D$. By induction hypothesis that is $c \in D$ already. (2) If $I = \emptyset$ then for any $i \in 1 \dots k$ we've got $p_i \nmid d$. But as p_k is prime and $p_k \mid cd$ this yields $p_k \mid c$, say $c = gp_k$. Then

$$\alpha p_1 \dots p_k \;=\; cd \;=\; gdp_k$$

We divide by p_k again to find $gd = \alpha p_1 \dots p_{k-1} \in D$. And by induction hypothesis this means $g \in D$. But $p_k \in D$ is clear, as well and therefore $c = gp_k \in D$ as claimed.

(ix) First consider the case $\alpha = 1 = \beta$. Without loss of generality we may assume $k \leq l$ and we will use induction k to prove the statement. If $k = 0$ we have to prove $l = 0$. Thus assume $l \geq 1$ then $1 = q_1 \dots q_l = q_1(q_2 \dots q_l)$. That is $q_1 \in R^*$ is a unit. But q_1 has been prime and hence $q_1 \notin R^*$ a contradiction. Thus we necessarily have $k = l = 0$. Now consider the induction step $k \geq 1$, then $p_k \mid p_1 \dots p_k = q_1 \dots q_l$ and as p_k is prime this means $p_k \mid q_j$ for some $j \in 1 \dots l$. Without loss of generality we may assume $j = l$. Hence we found $q_l = \gamma p_k$ for some $\gamma \in R$. But q_l has been prime and hence is irreducible by (iv). This means $\gamma \in R^*$ (as $p_k \notin R^*$) and hence $p_k \approx q_k$. Further we have

$$(p_1 \dots p_{k-1})p_k \;=\; p_1 \dots p_k \;=\; q_1 \dots q_l \;=\; \gamma(q_1 \dots q_{l-1})p_k$$

As $p_k \neq 0$ and R is an integral domain we may divide by p_k and thereby get $p_1 \dots p_{k-1} = (\gamma q_1)q_2 \dots q_{l-1}$. (As γq_1 is prime again) the induction hypothesis now yields that $k - 1 = l - 1$ and there is some $\sigma \in S_{k-1}$ such that for any $i \in 1 \dots k-1$ we have $p_i \approx q_{\sigma(i)}$. But this also is $k = l$ and we may extend σ to S_k by letting $\sigma(k) := k = l$. (As $q_1 \approx \gamma q_1$) we hence found $p_i \approx q_{\sigma(i)}$ for any $i \in 1 \dots k$. Thus we have completed the case $\alpha = 1 = \beta$. If now α and $\beta \in R^*$ are arbitrary, then we let $p'_1 := \alpha p_1$, $p'_i := p_i$ (for $i \in 2 \dots k$) and $q'_1 := \beta q_1$, $q'_j := q_j$ (for $j \in 2 \dots l$). By (iii) p'_i and q'_j are prime again and by construciton it is clear that $p'_i \approx p_i$ and $q'_j \approx q_j$ for any $i \in 1 \dots k$ and $j \in 1 \dots l$. As $p'_1 \dots p'_k = q'_1 \dots q'_l$ we may invoke the first case to find $k = l$ and the required permutation $\sigma \in S_k$. But now for any $i \in 1 \dots k$ we get $p_i \approx p'_1 \approx q'_{\sigma(i)} \approx q_{\sigma(i)}$ and hence $p_i \approx q_{\sigma(i)}$ as claimed.

(x) We only prove the equivalence for the least common multiple (the like statement for the greatest common divisor can be proved in complete analogy). Clearly $m \in mR^* = \operatorname{lcm}(A)$ implies $m \in \operatorname{lcm}(A)$. Thus let us assume $m \in \operatorname{lcm}(A)$, then we need to prove $\operatorname{lcm}(A) = mR^*$. For " $\supseteq$ " we are given any $\alpha \in R^*$. As $A \mid m$ it is clear that $A \mid \alpha m$, as well. And if $A \mid n$ then $m \mid n$ (by assumption) and hence also $\alpha m \mid n$ (by $(\alpha m)(\alpha^{-1}h) = n$ for $mh = n$). Concersely for " $\subseteq$ " consider $n \in \operatorname{lcm}(A)$. As $A \mid m$ and $n \in \operatorname{lcm}(A)$ we get $n \mid m$. Analogously $A \mid n$ and $m \in \operatorname{lcm}(A)$ impliy $m \mid n$. Together that is $m \approx n$ and hence $n = \alpha n$ for some $\alpha \in R^*$.

□

Proof of (2.57):

(i) If $A = \{a\}$ then $A \mid a$ is clear. Also $A \mid n$ is $a \mid n$ [for any $n \in R$] such that $A \mid n$ trivially implies $a \mid n$. Therefore $a \in \operatorname{lcm}(A)$. And $a \in \gcd(A)$ can be seen in complete analogy.

(ii) Let us denote $B := A \cup \{1\}$, then $B \mid n$ is equivalent to $A \mid n$ [for any $n \in R$], as $1 \mid n$ is always satisfied. In particular properties (1) of a least common multiple $m \in R$ of A and B are the same. Linekwise for property (2) $B \mid n \implies m \mid n$. As we can substitute $B \mid n$ by $A \mid n$ property (2) agrees, as well. From this we find that $m \in \operatorname{lcm}(B)$ is equivalent to $m \in \operatorname{lcm}(A)$.

Likewise for $B := A \cup \{0\}$ we find that $c \mid B$ is equivalent to $c \mid A$ [for any $c \in R$], as $c \mid 0$ is always satisfied. In complete analogy to the above we find that $d \in \gcd(B)$ is equivalent to $d \in \gcd(A)$.

(iii) If $A = \{0\}$ then we have already seen $0 \in \gcd(A)$ and $0 \in \operatorname{lcm}(A)$ in (i). It remains to show the converse implications: If $0 \in \gcd(A)$ then in particular $0 \mid A$. That is for any $a \in A$ we have $0 \mid a$. But this means $a = 0$ such that necessarily $A = \{0\}$.

Now let R be an integral domain and A be finite. Suppose we had $A \neq \{0\}$, letting $A' := A \setminus \{0\} \neq \emptyset$ (ii) tells us that $\operatorname{lcm}(A) = \operatorname{lcm}(A')$. As A is finite, so is A' say $A' = \{a_1, \ldots, a_k\}$. By assumption we have $0 \in \operatorname{lcm}(A) = \operatorname{lcm}(A')$ and in particular this means $A \mid n \implies n = 0$ for any $n \in R$. Therefore for any $n \neq 0$ we necessarily have $A \nmid n$, that is there is some $a \in A$ such that $a \nmid n$. Now take $n := a_1 \ldots a_k$ as R is an integral domain and $a_i \neq 0$ we also have $n \neq 0$. By assumption there is some $a_i \in A'$ such that $a_i \nmid n = a_1 \ldots a_k$ which is absurd. This contradicion yields $A' = \emptyset$ and hence $A = \{0\}$.

(iv) We only need to prove $\mathbb{N} \mid k \iff k = 0$ for any $k \in \mathbb{Z}$. If $k = 0$ then $k = 0 = n \cdot 0$ for any $n \in \mathbb{N}$ and hence $n \mid k$. Conversely suppose $\mathbb{N} \mid k$, then we choose $n := 2|k| \in \mathbb{N}$. As $n \mid k$ there is some $a \in \mathbb{Z}$ such that $\pm 2ak = an = k$ or equivalently $k(1 \mp 2a) = 0$. As 2 is not a unit of $\mathbb{Z}$ this only leaves $k = 0$. And form this equivalence it is clear, that $\operatorname{lcm}(\mathbb{Z}) = \{0\}$.

□

Proof of (2.59):

(i) Suppose $\langle a \mid b \rangle = \infty$ that is for any $k \in \mathbb{N}$ there is some $h_k \in R$ such that $a^k h_k = b$. First suppose there was some $k \in \mathbb{N}$ such that $h_k = 0$. Then $b = a^k \cdot 0 = 0$, too and then $a \mid 0$ also implies $a = 0$, a contradiction. Thus $h_k \neq 0$ for any $k \in \mathbb{N}$. Now for any $k \in \mathbb{N}$ we find $h_{k+1} a^{k+1} = b = h_k a^k$. And as $a \neq 0$ and R is an integral domain $h_{k+1} a^{k+1} = h_k a^k$ also yields $h_{k+1} a = h_k$. That is $h_{k+1} \mid h_k$ and hence we have found the ascending chain of ideals

$$h_0 R \subseteq h_1 R \subseteq \ldots \subseteq h_k R \subseteq h_{k+1} R \subseteq \ldots$$

Now suppose we had $h_k R = h_{k+1} R$ at any one stage $k \in \mathbb{N}$. That is there is some $\alpha \in R$ such that $h_{k+1} = \alpha h_k$. Thereby we compute $h_k = a h_{k+1} = \alpha a h_k$. And as $h_k \neq 0$ this implies $\alpha a = 1$. That is $a \in R^*$ a contradiction to $a \in R^\bullet$. And this only leaves $\langle a \mid b \rangle < \infty$.

(ii) As p is prime we have $p \in R^\bullet$ and hence $\langle p \mid a \rangle < \infty$ due to (i) (likewise for b and ab). That is we let $k := \langle p \mid a \rangle$, $l := \langle p \mid b \rangle$ and $n := \langle p \mid ab \rangle \in \mathbb{N}$. Then by assumption there are some α, $\beta \in R$ such that $a = \alpha p^k$ and $b = \beta p^l$. In particular $ab = \alpha\beta p^{k+1}$ such that $p^{k+l} \mid ab$ and

hence $k+l \leq n$, as n is maximal among the integers with $p^n \mid ab$. Now suppose $n > k+l$, say $p^n h = ab = \alpha\beta p^{k+l}$. As R is an integral domain we may divide by p^{k+l} and thereby obtain $p^{n-(k+l)}h = \alpha\beta$. And as $n-(k+l) \geq 1$ this yields $p \mid \alpha\beta$. Now recall that p has been prime, then we may assume (w.l.o.g.) that $p \mid \alpha$, say $pg = \alpha$. Then $a = \alpha p^k = gp^{k+1}$ and hence $p^{k+1} \mid a$. But this is a contradiction to k being maximal and hence the assumption $n > k+l$ has to be dropped. Altogether we have found $n = k+l$.

The second property is an immediate consequence of the first: If $n = 0$, then $a^n = 1$ and $p \not| 1$, as p is a non-unit. We now use induction on n, $\langle p \mid a^{n+1}\rangle = \langle p \mid a\rangle + \langle p \mid a^n\rangle$ by the above. But by induction hypothesis, this is $\langle p \mid a\rangle + n \cdot \langle p \mid a\rangle = (n+1) \cdot \langle p \mid a\rangle$.

(♡) In a first step let us prove, that for any $a \in R^\bullet$ there is an irreducible $p \in R$ such that $p \mid a$. To do this we recursively define a sequence of elements, starting with $a_0 := a$. Now suppose we had already constructed $a_0, \ldots, a_k \in R$ such that $a_0R \subset a_1R \subset \ldots \subset a_kR$. Of course $a_k = 0$ cannot be, as $0 \neq a = a_0 \in a_kR$. Then we iterate as follows: if a_k is not irreducible then there are f, $g \in R^\bullet$ such that $a_k = fg$. Then by (2.58.(iv)) we get $a_kR = (fg)R \subset fR$. Thus if we now let $a_{k+1} := f$ then we have appended our chain of ideals to

$$a_0R \subset a_1R \subset \ldots \subset a_kR \subset a_{k+1}R$$

As R is noetherian we cannot construct a strictly ascending chain of infinite length. That is our construction has to terminate at some finite level $s \in \mathbb{N}$. And this can only be if $p := a_s$ is irreducible. Thus we have $a = a_0 \in a_0R \subseteq a_sR = pR$ and thereby $p \mid a$.

(iii) If $a \in R^*$ is a unit, then the claim is clear by choosing $\alpha := a$ and $k := 0$. Thus let us assume $a \in R^\bullet$. Then by (♡) above there is some irreducible element $p_1 \in R$ such that $p_1 \mid a$, say $p_1a_1 = a$. Thus suppose we have already constructed the elements $a_1, \ldots, a_k \in R$ and $p_1, \ldots, p_k \in R$ such that the p_i are irreducible, $a = a_kp_1 \ldots p_k$ and $aR \subset a_1R \subset \ldots \subset a_kR$. Suppose that $a_k \notin R^*$ is no unit, then we iterate as follows: Note that $a_k \neq 0$ as well (else $a = 0$) and hence $a_k \in R^\bullet$. Thus by (♡) there is some irreducible element $p_{k+1} \in R$ such that $p_{k+1} \mid a_k$, say $a_k = p_{k+1}a_{k+1}$. We note that by (2.58.(iv)) this implies $a_kR = (p_{k+1}a_{k+1})R \subset a_{k+1}R$. So we have found a_{k+1} and p_{k+1} irreducible such that $a_{k+1}p_1 \ldots p_{k+1} = a_kp_1 \ldots p_k = a$ and

$$aR \subset a_1R \subset \ldots \subset a_kR \subset a_{k+1}R$$

As R is noetherian we cannot construct a strictly ascending chain of infinite length. That is our construction has to terminate at some finite level $s \in \mathbb{N}$. And this can only be if $a_s \in R^*$ is a unit. Thus we let $\alpha := a_s$ and thereby get $a = \alpha p_1 \ldots p_s$ as claimed.

(iv) As R is noetherian and $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ is an ideal there are finitely many $a_i \in R$ such that $\mathfrak{p} = \langle a_1, \ldots, a_k\rangle_{\mathrm{i}}$. Without loss of generality we may assume $a_i \neq 0$ (else we might just as well drop it). Then we use (iii) to find a decomposition of a_i into irreducible elements $p_{i,j} \in R$

$$a_i = \alpha_i \prod_{j=1}^{n(i)} p_{i,j}$$

As $a_i \in \mathfrak{p}$ and $\mathfrak{p}$ is prime this means that for any $i \in 1 \ldots k$ there is some $j(i) \in 1 \ldots n(i)$ such that $p_{i,j} \in \mathfrak{p}$ (note that $\alpha_i \neq \mathfrak{p}$ as else $1 = \alpha_i^{-1}\alpha_i \in \mathfrak{p}$). Now let $p_i := p_{i,j(i)} \in \mathfrak{p}$. Then it is clear that

$$a_i \in p_i R \subseteq \langle p_1, \ldots, p_k \rangle_{\mathfrak{i}} \subseteq \mathfrak{p} = \langle a_1, \ldots, a_k \rangle_{\mathfrak{i}}$$

for any $i \in \ldots k$. And thereby $\mathfrak{p} = \langle a_1, \ldots, a_k \rangle_{\mathfrak{i}} \subseteq \langle p_1, \ldots, p_k \rangle_{\mathfrak{i}}$ as well such that we truly find $\mathfrak{p} = \langle p_1, \ldots, p_k \rangle_{\mathfrak{i}}$ as claimed.

(vi) Let us prove the first statement $a \mid b$ by induction over k. If $k = 0$ then $a = 1$ and hence $a \mid b$ is clear. Let us now fix some some abbreviations: let $n(i) := \langle q_i \mid b \rangle \in \mathbb{N}$ due to (i). And by definition of $\langle q_i \mid b \rangle$ it is clear that $q_i^{n(i)} \mid b$, say $b = b_i q_i^{n(i)}$ for any $i \in 1 \ldots k$. Hence in case $k = 1$ we are done already, as $a = q_1^{n(1)} \mid b$. Thus we may assume $k \geq 2$. Then the induction hypothesis reads as

$$h := \prod_{i=1}^{k-1} q_i^{n(i)} \;\Big|\; b$$

Assume that $q_k \mid h$, as q_k is prime (by construction of h) this would mean $q_k \mid q_i$ for some $i \in 1 \ldots k-1$. That is $q_i = \alpha_i q_k$ for some $\alpha_i \in R$. But as R is an integral domain and q_i is prime it also is irreducible by (2.58.(v)). This yields $\alpha_i \in R^*$ and hence $q_i \approx q_k$. But by assumption this is $i = k$ in contradiction to $i \in 1 \ldots k-1$. Thus we have seen $q_k \not| h$, or in other words $\langle q_k \mid h \rangle = 0$. Now recall that $h \mid b$, that is there is some $g \in R$ such that $b = gh$. then we may easily compute (using (ii))

$$n(k) = \langle q_k \mid b \rangle = \langle q_k \mid gh \rangle = \langle q_k \mid g \rangle + \langle q_k \mid h \rangle = \langle q_k \mid g \rangle$$

That is $q_k^{n(k)} = q_k^{\langle q_k | g \rangle} \mid g$ such that $g = q_k^{n(k)} f$ for some $f \in R$. Multiplying this identity with h we finally find $a \mid b$ from

$$b = gh = q_k^{n(k)} fh = af$$

It remains to verify the second claim in (vi). That is consider any prime element $p \in R$ such that $p \mid b = af$. As p is prime this means $p \mid a$ or $p \mid f$. In the first case $p \mid a$ (by construction of a) we find some $i \in 1 \ldots k$ such that $p \mid q_i$. That is $\alpha p = q_i$ for some $\alpha \in R$. Again we use that q_i is prime and hence irreducible to deduce that $\alpha \in R^*$ and hence $p \approx q_i$. In the second case $p \mid f$ we are done already, as $f = b/a$. Thus we have proved $p \mid (b/a)$ *or* $p \approx p_i$ for some $i \in 1 \ldots k$. Now suppose *both* statements would be true, that is $p \mid f$ *and* (w.l.o.g.) $p \mid q_k$. That is $f = pr$ and $q_k = \alpha p$ for some $r \in R$ and $\alpha \in R^*$. Then we compute

$$b = af = \big(hq_k^{n(k)}\big)\big(\alpha^{-1} q_k r\big) = q_k^{n(k)+1}\big(\alpha^{-1} hr\big)$$

In particular $q_k^{n(k)+1} \mid b$. But this clearly is a contradiction to the maximality of $n(k) = \langle q_k \mid b \rangle$. Thus we have proved the truth of *either* $p \mid (b/a)$ *or* $p \approx q_i$ (and not *both*) as claimed.

(v) Suppose we had $a \in pR$ for infinitely many $p \in P$. In particular we may choose a countable subset $(p_i) \subseteq P$ such that $a \in p_i R$ for any $i \in \mathbb{N}$. By (vi) we get

$$a_k := \prod_{i=0}^{k} p_i^{\langle p_i | a \rangle} \;\Big|\; a$$

From the construction it is clear that for $f_k := p_k^{\langle p_k | a \rangle}$ we get $a_{k-1} f_k = a_k$. And as $p_k \mid a$ we have $\langle p_k \mid a \rangle \geq 1$ such that $f_k \neq 1$. In fact $f_k \in R^\bullet$ as $p_k \in R^\bullet$ and R is an integral domain. Next let us choose some $g_k \in R$ such that $a = a_k g_k$. Then for any $k \in \mathbb{N}$ we get $a_k g_k = a = a_{k+1} g_{k+1} = a_k f_{k+1} g_{k+1}$. It is clear that $a_k \neq 0$, as else $a = 0 \cdot g_k = 0$. Thus we may divide a_k from $a_k g_k = a_k f_{k+1} g_{k+1}$ and thereby find $g_k = f_{k+1} g_{k+1}$. Now using (2.58.(iv)) with $g_{k+1} \neq 0$ and $f_{k+1} \in R^\bullet$ we find $g_k R \subset g_{k+1} R$. As this is true for any $k \in \mathbb{N}$ we have found an infinitely ascending chain

$$g_0 R \subset g_1 R \subset g_2 R \subset \dots$$

of ideals in R. But this is a contradiction to R being noetherian. Thus the assumption has to be false and that is: there are only finitely many $p \in P$ with $a \in pR$.

□

Proof of (2.60):

In a first step we will prove the equivalence of (a), (b) and (c). Using these as a definition we will prove some more properties of UFDs first, before we continue with the proof of the equivalences of (d), (e) and (f) on page (1100).

- (a) $\implies$ (c): By (2.58.(v)) we already know that prime elements are irreducible (as R is an integral domain). From this (1) and the one part of (2) are trivial by assumption (a). We only have to prove the second part of (2): $\forall\, q \in R : q$ irreducible $\implies q$ prime. By assumption (a) q admits a prime decomposition $q = \alpha p_1 \dots p_k$. It is clear that $k \neq 0$ as else $q \in R^*$. Now suppose $k \geq 2$ then we would write q as $q = (\alpha q_1)(q_2 \dots q_k)$. And as q is irreducible this would mean $\alpha p_i \in R^*$ or $p_2 \dots p_k \in R^*$. But as p_1 is prime, so is αp_1 - by (2.58.(iii)) - and as R is an integral domain $R^\bullet$ is closed under multiplication such that $p_2 \dots p_k \in R^\bullet$. Hence none of this can be and this only leaves $k = 1$. That is $q = \alpha p_1$ and hence q is prime.

- (c) $\implies$ (b): consider any $0 \neq a \in R$, property (1) in (b) and (c) are identical so we only need to verify (2) in (b). Thus let $(\alpha, p_1, \dots, p_k)$ and $(\beta, q_1, \dots, q_l)$ be two irreducible decompositions of a. By assumption (2) in (c) all the p_i and p_j are prime already. Therefore $\alpha p_1 \dots p_k = a = \beta q_1 \dots q_l$ implies $k = l$ and $p_i = q_{\sigma(i)}$ (for some $\sigma \in S_k$ and any $i \in 1 \dots k$) by (2.58.(vii)). And by definition this already is $(\alpha, p_1, \dots, p_k) \approx (\beta, q_1, \dots, q_l)$.

- (b) $\implies$ (a): By assumption (b) any $0 \neq a \in R$ has an irreducible decomposition. Thus it suffices to show that any irreducible element $p \in R$ already is prime. Thus consider an irreducible $p \in R$ and arbitrary $a, b \in R$. Then we need to show $p \mid ab \implies p \mid a$ or $p \mid b$. To do this we write down irreducible decompositions of a and b

$$a = \alpha p_1 \dots p_k \quad \text{and} \quad b = \beta p_{k+1} \dots p_{k+l}$$

As $p \mid ab$ there is some $h \in R$ with $ab = ph$. Again we use an irreducible decomposition of $h = \gamma q_1 \dots q_m$. Finally let $q_{m+1} := p$

$$\gamma q_1 \dots q_m q_{m+1} = ph = ab = \alpha\beta p_1 \dots p_{k+l}$$

As all the p_i and q_j are irreducible assumption (2) now yields that $n := m + 1 = k + l$ and that

there is some $\sigma \in S_n$ such that for any $i \in 1 \ldots n$ we get $q_i \approx p_{\sigma(i)}$. Now let $j := \sigma(m+1)$, that is $p = q_{m+1} \approx p_j$. If $j \in 1 \ldots k$ then $p \approx p_j \mid a$ and hence $p \mid a$. Likewise if $j \in k+1 \ldots k+l$ then $p \approx p_j \mid b$ and hence $p \mid b$. Together this means that p is truly prime.

□

Proof of (2.64):
Until now we only have proved the equivalence of (a), (b) and (c) in the definition of an UFD. That is we understand by an UFD an integral domain satisfying (a) (equivalently (b) or (c)). And using this definition only we are able to prove the theorem given:

(i) Let $I := \{i \in 1 \ldots k \mid p \approx p_i\}$ and $n := \#I$. Then for any $i \in I$ there is some $\alpha_i \in R^*$ such that $p_i = \alpha_i p$. Then it is immediately clear that

$$a \;=\; \beta b p^n \quad \text{where} \quad \beta := \alpha \prod_{i \in I} \alpha_i \quad \text{and} \quad b := \prod_{j \notin I} p_j$$

In particular $p^n \mid a$ and this means $n \leq \langle p \mid a \rangle$. Conversely suppose $p^m \mid a$ for some $m > n$, say $p^m h = a = \beta b p^n$. Then $p^{m-n} \beta^{-1} h = b$ and hence $p \mid b$ as $p \mathrm{dim} p^{m-n}$. By definition of b this would imply $p \mid p_j$ for some $j \notin I$. Say $p_j = \gamma p$ for some $\gamma \in R$. But as p_j is irreducible (and $p \notin R^*$ this yields $\gamma \in R^*$ and hence $p \approx p_j$ in contradiction to $j \notin I$. Thus we have proved the maximality of n and hence $n = \langle p \mid a \rangle$.

(ii) Using (i) this boils down to an easy computation: pick up two prime decompositions $a = \alpha p_1 \ldots p_k$ and $b = \beta q_1 \ldots q_l$. For $j \in 1 \ldots l$ we let $p_{k+j} := q_j$. Then it is clear that $ab = \alpha\beta p_1 \ldots p_{k+l}$ and thereby

$$\begin{aligned} \langle p \mid ab \rangle &= \#\{\, i \in 1 \ldots (k+l) \mid p \approx p_i \,\} \\ &= \#\{\, i \in 1 \ldots k \mid p \approx p_i \,\} + \#\{\, j \in 1 \ldots l \mid p \approx q_j \,\} \\ &= \langle p \mid a \rangle + \langle p \mid b \rangle \end{aligned}$$

The reasoning for the power to multiple property is precisely the same, as in the case of a noetherian integral domain, please refer to (2.59.(ii)).

(v) *Existence:* consider any $0 \neq a \in R$ and pick up a prime decomposition $a = \beta q_1 \ldots q_k$ of a. As the q_i is prime there is a uniquely determined $p_i \in \mathbb{P}$ such that $q_i \approx p_i$, say $q_i = \alpha_i p_i$ for some $\alpha_i \in R^*$. Then

$$a = \alpha p_1 \ldots p_k \quad \text{where} \quad \alpha := \alpha_1 \ldots \alpha_k$$

For any $p \in \mathbb{P}$ now let $n(p) := \#\{\, i \in 1 \ldots k \mid p_i = p \,\} \in \mathbb{N}$. Then it is clear that only finitely many $n(p)$ are non-zero, as they sum up to

$$\sum_{p \in \mathbb{P}} n(p) \;=\; k$$

That is $n \in \oplus_p \mathbb{N}$ And further it is clear that a has the representation

$$a \;=\; \alpha \prod_{i=1}^{k} p_i \;=\; \alpha \prod_{p \in \mathbb{P}} p^{n(p)}$$

Uniqueness: Consider any $a \neq 0$ represented as $a = \alpha \prod_p p^{n(p)}$ as presented in the theorem. Then we fix any $q \in \mathbb{P}$, it is clear that

$$a \;=\; \alpha h q^{n(q)} \quad \text{where} \quad h := \prod_{p \neq q} p^{n(p)}$$

It is clear that $\langle q \mid q^n \rangle = n$, as $q^n \mid q^n$ and $q^{n+1} \mid q$ would imply $q \mid 1$ and hence $q \in R^*$. Further it is easy to see that $\langle q \mid \alpha h \rangle = 0$. Because if $q \mid \alpha h$ then $q \mid h$ (as $\alpha \in R^*$) and hence there has to be some $p \neq q$ such that $q \mid p$. That would be $q \approx p$ due to the irreducibility of p in contradiction to $p \neq q$ (as $\mathbb{P}$ was a representing system). Hence we may use (i) again to find

$$\langle q \mid a \rangle \;=\; \langle q \mid \alpha h q^{n(q)} \rangle \;=\; \langle q \mid \alpha h \rangle + \langle q \mid q^{n(q)} \rangle \;=\; n(q)$$

In particular the exponent $n(q)$ in this representation of a is uniquely determined to be $\langle q \mid a \rangle$. And as q has been arbitrary this means that n is uniquely determined. And as R is an integral domain this finally yields that α is uniquely determined, as well.

(iii) Suppose $b = ah$ for some $h \in R$. Then for any $p \in R$ prime we get $\langle p \mid b \rangle = \langle p \mid ah \rangle = \langle p \mid a \rangle + \langle p \mid h \rangle \geq \langle p \mid a \rangle$. Conversely suppose $\langle p \mid a \rangle \leq \langle p \mid b \rangle$ for any $p \in R$ prime. Pick up a representing system $\mathbb{P}$ and use it to write a and b in the form

$$a \;=\; \alpha \prod_{p \in \mathbb{P}} p^{m(p)} \quad \text{and} \quad b \;=\; \beta \prod_{p \in \mathbb{P}} p^{n(p)}$$

By assumption we have $m(p) = \langle p \mid a \rangle \leq \langle p \mid b \rangle = n(p)$. That is $k(p) := n(p) - m(p) \geq 0$. Hence we explicitly find some $h \in R$ such that

$$b \;=\; ah \quad \text{where} \quad h \;:=\; \alpha^{-1} \beta \prod_{p \in \mathbb{P}} p^{k(p)}$$

(iv) Pick up a representing system $\mathbb{P} \subseteq R^\bullet$ of the prime elements of R modulo associateness. Then according to (v) we find

$$\begin{aligned} a &= \alpha \prod_{p \in \mathbb{P}} p^{\langle p|a \rangle} \\ b &= \beta \prod_{p \in \mathbb{P}} p^{\langle p|b \rangle} \end{aligned}$$

for some units $\alpha, \beta \in R^*$. Hence $ab = \alpha\beta \prod_p p^{\langle p|a\rangle + \langle p|b\rangle}$ such that (iii) applied to $d \mid ab$ yields the following upper bound

$$\forall\, p \in \mathbb{P} \;:\; \langle p \mid d \rangle \;\leq\; \langle p \mid a \rangle + \langle p \mid b \rangle$$

If there was some $p \in \mathbb{P}$ with $\langle p \mid a \rangle \neq 0$ and $\langle p \mid d \rangle \neq 0$ then p would be a common divisor of a and d in contradiction to $1 \in \gcd\{a, d\}$. Hence we have

$$\forall\, p \in \mathbb{P} \;:\; \langle p \mid d \rangle \neq 0 \implies \langle p \mid a \rangle = 0$$

That is we get $\langle p \mid d \rangle \leq \langle p \mid b \rangle$ for any $p \in \mathbb{P}$ with $\langle p \mid d \rangle \neq 0$. In case $\langle p \mid d \rangle = 0$ however

$\langle p \mid d\rangle \leq \langle p \mid b\rangle$ is satisfied trivially. So we altogether have $\langle p \mid d\rangle \leq \langle p \mid b\rangle$ for *any* $p \in \mathbb{P}$. And according to (iii) again, this truly implies $d \mid b$.

(vi) Let us abbreviate $d := \prod_p p^{m(p)}$ then we need to verify that d is a greatest common divisor of A. By definition of $m(p)$ we have $\langle p \mid d\rangle = m(p) \leq \langle p \mid a\rangle$ for any $p \in \mathbb{P}$ and any $a \in A$. And by (iii) that is $d \mid a$ and for any $a \in A$ and hence $d \mid A$. Conversely consider any $c \in R$ with $c \mid A$. In particular we have $c \neq 0$ as $0 \notin A \neq \emptyset$. And hence $c \mid a$ implies $\langle p \mid c\rangle \leq \langle p \mid a\rangle$ for any $p \in \mathbb{P}$ (and $a \in A$) by (iii) again. This is $\langle p \mid c\rangle \leq m(p) = \langle p \mid d\rangle$ for any $p \in \mathbb{P}$ and hence $c \mid d$ by (iii). The statement for the least common multiple can be proved in complete analogy. We only have to note that the assumption $\#A < \infty$ guarantees $n \in \oplus_p \mathbb{N}$ again.

(vii) Once more we choose a representing system $\mathbb{P}$ of the primes of R. And for any $p \in \mathbb{P}$ let us abbreviate $m(p) := \min\{\langle p \mid a\rangle, \langle p \mid b\rangle\}$ and likewise $n(p) := \min\{\langle p \mid a\rangle, \langle p \mid b\rangle\}$. Then it is a standard fact that $m(p) + n(p) = \langle p \mid a\rangle + \langle p \mid b\rangle$. By (ii) and (v) that is

$$\begin{aligned} \langle p \mid ab\rangle &= \langle p \mid a\rangle + \langle p \mid b\rangle = m(p) + n(p) \\ &= \langle p \mid a\rangle + \langle p \mid b\rangle = \langle p \mid dm\rangle \end{aligned}$$

And as this holds true for any $p \in \mathbb{P}$ (iv) immediately yields the claim.

(viii) We commence with the notation of (vi) and choose any $e \in \gcd\{a, b, c\}$. Then by (v) the order of $p \in \mathbb{P}$ in c is given to be the following

$$\begin{aligned} \langle p \mid e\rangle &= \min\{\, \langle p \mid a\rangle, \langle p \mid b\rangle, \langle p \mid c\rangle \,\} \\ &= \min\{\, \min\{\, \langle p \mid a\rangle, \langle p \mid b\rangle \,\}, \langle p \mid c\rangle \,\} \\ &= \min\{\, \langle p \mid d\rangle, \langle p \mid c\rangle \,\} = \langle p \mid e'\rangle \end{aligned}$$

And the latter is the order of any greatest common divisor of $e' \in \gcd\{c, d\}$. As this is true for any $p \in \mathbb{P}$ we thereby find that e and e' are associated. The claim for the greatest common divisors follows immediately. The analogous argumentation also rests the case for the least common multiples.

□

Proof of (2.65):
As R is an UFD, it is an integral domain, by definition. Thus choose any $0 \neq x = b/a \in \mathrm{QUOT}(R)$ that is integral over R, i.e. $\exists\, a_1, \ldots, a_n \in R$ with

$$x^n + a_1 x^{n-1} + \cdots + a_n = 0$$

Then we need to show that $a \mid b$ already. But as R is an UFD we may let $d := \gcd\{a, b\}$ and write $a = \alpha d$ and $b = \beta d$. Then α and β are relatively prime and $a \mid b$ can be put as $\alpha \in R^*$ (as then $b = (\alpha^{-1}\beta)a$). By multiplying the above equation with α^n we find (note $x = \beta/\alpha$)

$$\beta^n + \alpha\,(a_1\beta^{n-1} + \cdots + \alpha^{n-1}a_n) = 0$$

And hence α divides β^n - but as α and β were relatively prime, so are α and β^n. But together this implies that α truly is a unit of R. □

Proof of (2.66):

(ii) We first prove the irreducibility of $2 \in \mathbb{Z}[\sqrt{-3}]$. Thus let $\omega := i\sqrt{3}$ and suppose $2 = (a+b\omega)(c+d\omega)$. Then by complex conjugation we find $2 = (a-b\omega)(c-d\omega)$. Multiplying these two equations we get

$$4 \;=\; 2\cdot 2 \;=\; (a^2+3b^2)(c^2+3d^2) \;\geq\; 9(bd)^2$$

Thus if both $b \neq 0$ and $d \neq 0$ this formula ends up with the contradicion $4 \geq 9(bd)^2 \geq 9$. Thus without loss of generality (interchanging a, c and b, d if necessary) we may assume $d = 0$. Then we have

$$4 \;=\; (a^2+3b^2)c^2$$

Of course $c = 0$ cannot be (else $4 = 0$). If $|c| = 1$ then $c + d\omega = \pm 1$ which of course is a unit in $\mathbb{Z}[\sqrt{-3}]$. Thus suppose $|c| \geq 2$ then $c^2 \geq 4$ such that necessarily $a^2 + 3b^2 = 1$. This of course can only be if $a = 1$ and $b = 0$ such that now $a + b\omega$ is a unit of $\mathbb{Z}[\sqrt{-3}]$. Altogether 2 is irreducible.

- On the other hand $2 \mid 4 = (1+\omega)(1-\omega)$. Now suppose we had $2 \mid 1+\omega$, say $2(a+b\omega) = 1+\omega$. Then $2a = 1$ and hence $2 =\in \mathbb{Z}^*$ which is false. Likewise we see that 2 does not divide $1-\omega$ and this means that 2 is not prime.

(iii) We first prove that $p = s^2 + t^2 - 1$ is irreducible in $\mathbb{R}[s,t]$. To do this we fix the graded lexicographic order on $\mathbb{R}[s,t]$, that is $\mathbb{R}[s,t]$ is ordered by (total) degree and by $s < t$. Now consider any two polynomials $f, g \in \mathbb{R}[s,t]$ such that $fg = p$. Then

$$\mathrm{lt}(f)\mathrm{lt}(g) \;=\; \mathrm{lt}(fg) \;=\; \mathrm{lt}(p) \;=\; \mathrm{lt}(-1+s^2+t^2) \;=\; t^2$$

By prime decomposition of the leading coefficient in $\mathbb{R}[s,t]$ we see that either $lt(f) = 1$, $\mathrm{lt}(f) = t$ or $\mathrm{lt}(f) = t^2$. If $\mathrm{lt}(f) = 1$ then f is a unit in $\mathbb{R}[s,t]$, likewise if $\mathrm{lt}(f) = t^2$ then $\mathrm{lt}(g) = 1$ and hence g is a unit in $\mathbb{R}[s,t]$. thus we only have to exclude the case $\mathrm{lt}(f) = t$. But in this case $\mathrm{lt}(g) = t$ as well such that

$$\begin{aligned} f &= a + bs + ct \\ g &= u + vs + wt \end{aligned}$$

for some coefficients a, b, c, u, v and $w \in \mathbb{R}$. From this we may compute fg and compare its coefficients with those of p. Doing this an easy computation yields

(1)	au	=	-1	constant term
(2)	$av + bu$	=	0	s-term
(3)	$aw + cu$	=	0	t-term
(4)	bv	=	1	s^2-term
(5)	$bw + cv$	=	0	st-term
(6)	cw	=	1	t^2-term

In particular $a \neq 0$ and hence we may regard $(f/a)(ag) = fg = p$ instead. That is we may assume $a = 1$, then $u = -1$ by (1). And thus (2) turns into $b = v$ and (3) becomes $c = w$. From this and (5) we get $2bc = 0$. That is $b = 0$ or $c = 0$. But $b = 0$ would be a contradiction to (4) and $c = 0$ would be a contradiction to (6). Thus $\mathrm{lc}(f) = t$ cannot occur and this is the irreducibility of p.

- We now prove that $R = \mathbb{R}[s,t]/\mathfrak{p}$ is no UFD. To do this let us denote the set $X := \{\, (x,y) \in \mathbb{R}^2 \mid x^2 + y^2 = 1 \,\}$. And thereby we define the following multiplicatively closed subset of R

$$U \;:=\; \{\, f + \mathfrak{p} \in R \mid \forall\, (x,y) \in X \,:\, f(x,y) \neq 0 \,\}$$

 By construction it is clear that U is truly well defined (if $f - g = q \in \mathfrak{p}$ then for any $(x,y) \in X$ we get $f(x,y) = g(x,y) + q(x,y) = g(x,y)$) and multiplicatively closed (as $\mathbb{R}$ is an integral domain). Let us now denote the element $r := s + \mathfrak{p} \in R$. Then we will prove that $r/1 \in U^{-1}R$ is irreducible but not prime. Thus $U^{-1}R$ is no UFD and hence R has not been an UFD by virtue of (2.131).

- Let us first prove that $r/1$ is not prime. To do this let us define the following elements $a := 2(t+1) + \mathfrak{p}$ and $b := -2(t-1) + \mathfrak{p} \in R$. Then $ab = -4(t^2-1) + \mathfrak{p} = 4s^2 + \mathfrak{p} = 4r^2$. In particular $r \mid ab$ and hence $r/1 \mid (ab)/1 = (a/1)(b/1)$. Now assume $r/1 \mid a/1$ that is there are some $h + \mathfrak{p} \in R$ and $u + \mathfrak{p} \in U$ such that $a/1 = (r/1)(h + \mathfrak{p}/u + \mathfrak{p})$. As $\mathbb{R}[s,t]$ is an integral domain that is $2(t+1)u + \mathfrak{p} = sh + \mathfrak{p}$ or in other words $2(t+1)u - sh =: q \in \mathfrak{p}$. Now regard $(0,1) \in X$ then $0 = q(0,1) = 4u(0,1) \neq 0$, a contradiction. That is $r/1 \not| \; a/1$ and likewise we find $r/1 \not| \; b/1$ by regarding $(0,-1) \in X$.

- So it only remains to prove that $r/1$ is irreducible. Thus suppose there are some $f, g \in \mathbb{R}[s,t]$ and $u + \mathfrak{p}$, $v + \mathfrak{p} \in U$ such that

$$\frac{s+\mathfrak{p}}{1} \;=\; \frac{r}{1} \;=\; \frac{f+\mathfrak{p}}{u+\mathfrak{p}}\frac{g+\mathfrak{p}}{v+\mathfrak{p}} \;=\; \frac{fg+\mathfrak{p}}{uv+\mathfrak{p}}$$

 That is $suv + \mathfrak{p} = fg + \mathfrak{p}$ or in other words $suv - fg =: q \in \mathfrak{p}$. As $q \in \mathfrak{p} = p\mathbb{R}[s,t]$ and p vanishes on X identically, so does q. And this means that for any $(x,y) \in X$ we have the following identity

$$xu(x,y)v(x,y) \;=\; f(x,y)g(x,y)$$

 In particular fg and suv and have the same roots. And as u, v do not vanish on X these are precisely the points $(0,1)$ and $(0,-1) \in X$. If f does not vanish on X then $f + \mathfrak{p} \in U$ and hence $f + \mathfrak{p}/u + \mathfrak{p}$ is a unit of $U^{-1}R$. Likewise if g does not vanish on X then $g + \mathfrak{p}/v + \mathfrak{p}$ is a unit of $U^{-1}R$. Thus in order to prove the irreducibility of $r/1$ it suffices to check that at f or g does not vanish on X.

- Thus assume this was false, that is f and g vanish on at least one point, say $f(0,1) = 0$ and $g(0,-1) = 0$ (else interchange f and g). We now parametrisize X using the following curve

$$\Omega \,:\, [0,2\pi] \twoheadrightarrow X \,:\, \omega \mapsto \begin{pmatrix} \cos(\omega) \\ \sin(\omega) \end{pmatrix}$$

 First suppose neither $f(0,-1) = 0$ nor $g(0,1) = 0$, that is f and g both have precisely one root on X. Then f cannot change signs on X (else $[0,2\pi] \to \mathbb{R} : \omega \mapsto f\Omega(\omega)$ would have to

have at least two roots because of $f\Omega(0) = f\Omega(2\pi) \neq 0$). And the same is true for g. Thus $(x,y) \mapsto f(x,y)g(x,y)$ *does not* change sign on X. Likewise uv does not have a single root on X and hence its sign on X is constant. Hence $(x,y) \mapsto xu(x,y)v(x,y)$ *does* change sign in contradiction to the equality of these two functions. Thus at least one of the two f or g even has to have two roots on X.

- We only regard the case $f(0,1) = 0$ and $g(0,1) = 0 = g(0,-1)$. The other case (where f has both roots) is completely analogous. The basic ideas is the following: as both f and g vanish in $(0,1)$ this is a root of order 2 for fg. But xuv only has a root of order 1 in $(0,1)$. Thus let us do same basic calculus - we have $\Omega(\pi/2) = (0,1)$ and in this point we get $\Omega'(\pi/2) = (1,0)$. Thus in this case we find another contradiction to $suv = fg$ by evaluating

$$\begin{aligned}\big((suv)\Omega\big)'(\pi/2) &= \langle \begin{pmatrix} uv + sv\partial_s u + su\partial_s v \\ sv\partial_t u + su\partial_t v \end{pmatrix} \begin{pmatrix} 0 \\ 1 \end{pmatrix} \mid \begin{pmatrix} 1 \\ 0 \end{pmatrix} \rangle \\ &= u(0,1)v(0,1) \neq 0\end{aligned}$$

$$\begin{aligned}\big((fg)\Omega\big)'(\pi/2) &= \langle \begin{pmatrix} g\partial_s f + g\partial_s g \\ g\partial_t f + g\partial_t f \end{pmatrix} \begin{pmatrix} 0 \\ 1 \end{pmatrix} \mid \begin{pmatrix} 1 \\ 0 \end{pmatrix} \rangle \\ &= \langle (0,0) \mid (1,0) \rangle = 0\end{aligned}$$

Proof of (2.71):

(ii) First consider $a > 0$, then it is clear that $q := b \operatorname{div} a \in \mathbb{Z}$ exists, as the set $\{q \in \mathbb{Z} \mid aq \leq b\} =]-\infty, b/a] \cap \mathbb{Z}$ contains the maximal element $q = a/b$ rounded down. And from the construction of $r := b \bmod a$ it is clear that $b = aq + r$. From the definition of q it is also clear that $0 \leq r$. Now assume $r \geq a$ then $a(q+1) = aq + a \leq aq + r = b$ and hence q would not have been maximal - a contradiction. Thus we also have $0 \leq r < a$ and hence $\alpha(r) = r < a = \alpha(a)$. Thus we have established the division with remainder for $a > 0$. If conversely $a < 0$ then $-a > 0$ and hence we may let $q := (-b) \operatorname{div} (-a)$ and $r := -((-b) \operatorname{div} (-a))$. Then we have just proved $-b = q(-a) - r$ which yields $b = qa + r$ and $\alpha(r) = \alpha(-r) < \alpha(-a) = \alpha(a)$.

(iii) Consider any $g \in E[t]$, $0 \neq f \in E[t]$ and let $\alpha := \operatorname{lc}(f)$. Then $\overline{f} := \alpha^{-1} f \in E[t]$ is normed. Further let $\overline{g} := \alpha^{-1} g$. Then by (2.67) there are $q, r \in E[t]$ such that $\overline{g} = q\overline{f} + r$. Multiplying with α we find $g = qf + \alpha r$ and $\deg(\alpha r) = \deg(r) < \deg(f)$ (as $\alpha \in E^*$). Thus we have established the division with remainder on $E[t]$.

(iv) It is straightforward to check that $\mathbb{Z}[\sqrt{d}]$ truly is a sub-ring of $\mathbb{C}$. Clearly $0 = 0 + 0\sqrt{d} \in \mathbb{Z}[\sqrt{d}]$ and $1 = 1 + 0\sqrt{d} \in \mathbb{Z}[\sqrt{d}]$. Now consider $x = a + b\sqrt{d}$ and $y = f + g\sqrt{d} \in \mathbb{Z}[\sqrt{d}]$. Then it is clear that

$$\begin{aligned} x + y &= (a+f) + (b+g)\sqrt{d} \quad \in \mathbb{Z}[\sqrt{d}] \\ xy &= (af + dbg) + (ag + bf)\sqrt{d} \quad \in \mathbb{Z}[\sqrt{d}] \end{aligned}$$

Thus $\mathbb{Z}[\sqrt{d}]$ is a sub-ring of $\mathbb{C}$ and in particular an integral domain. Now assume $x = y$, then we wish to verify $(a,b) = (f,g)$ (the converse implication is clear). Assume we had $b \neq g$ then we

would be able to divide by $b-g \neq 0$ and hence get

$$\sqrt{d} \;=\; \frac{f-a}{b-g} \;\in\; \mathbb{Q}$$

a contradiction to the assumption $\sqrt{d} \notin \mathbb{Q}$. Thus we have $b = g$ and hence (substracting $b\sqrt{d} = g\sqrt{d}$) also $a = f$. Thus $x \mapsto \overline{x}$ is truly well defined and the bijectivity is clear. We also see $\overline{0} = 0 - 0\sqrt{d} = 0$ and $\overline{1} = 1 - 0\sqrt{d} = 1$ immediately. It remains to prove that $x \mapsto \overline{x}$ also is additive and multiplicative, by computing

$$\overline{x} + \overline{y} \;=\; (a - b\sqrt{d}) + (f - g\sqrt{d}) \;=\; (a+f) - (b+g)\sqrt{d}) \;=\; \overline{x+y}$$

$$\overline{xy} \;=\; (a - b\sqrt{d})(f - g\sqrt{d}) \;=\; (af + dbg) - (ag + bf)\sqrt{d} \;=\; \overline{xy}$$

But from this it is clear that ν also is multiplicative. Just compute $\nu(xy) = |xy\overline{xy}| = |x\overline{x}y\overline{y}| = |x\overline{x}| \cdot |y\overline{y}| = \nu(x)\nu(y)$. We finally note that for any $0 \neq x \in \mathbb{Z}[\sqrt{d}]$ we get $\nu(x) \neq 0$, since $\nu(x) = |a^2 - db^2| = 0$ is equivalent to $a^2 = db^2$. Thus if $b = 0$ then $a = 0$ and hence $x = 0$ as claimed. And if $b \neq 0$ then we may divide by b to find $(a/b)^2 = d$. In other words $\sqrt{d} = a/b \in \mathbb{Q}$, a contradiction to the assumption $\sqrt{d} \notin \mathbb{Q}$. Thus the case $b \neq 0$ cannot occur in the first place.

Next we prove that the units of $\mathbb{Z}[\sqrt{d}]$ are precisely the elements x such that $\nu(x) = 1$. If $x \in \mathbb{Z}[\sqrt{d}]^*$ is a unit, then we have $1 = \nu(1) = \nu(xx^{-1}) = \nu(x)\nu(x^{-1})$ and hence $\nu(x) \in \mathbb{Z}^*$. But as also $\nu(x) \geq 0$ this yields $\nu(x) = 1$. Thus consider any $x = a + b\sqrt{d} \in \mathbb{Z}[\sqrt{d}]$ such that $\nu(x) = 1$. Then $x\overline{x} = a^2 - db^2 = \pm 1$ and hence $x^{-1} = \pm\overline{x}$ is invertible.

Now assume that $d \leq -3$ then we want to prove that 2 is an irreducible element of $\mathbb{Z}[\sqrt{d}]$ that is not prime. We begin by proving that 2 is not prime: as either d or $d-1$ is even we have

$$2 \mid d(d-1) \;=\; d^2 - d \;=\; (d + \sqrt{d})(d - \sqrt{d})$$

but we have $2 \nmid d \pm \sqrt{d}$, because if we assume $2(a + b\sqrt{d}) = d \pm \sqrt{d}$ then (comparing the $\sqrt{d}$-coefficient) we had $2b = \pm 1 \in \mathbb{Z}$ in contradiction to $2 \notin \mathbb{Z}^*$. However 2 is irreducible, assume $2 = xy$ for some $x, y \in \mathbb{Z}[\sqrt{d}]$. Then $4 = \nu(2) = \nu(xy) = \nu(x)\nu(y)$. Hence we have $\nu(x) \in \{1, 2, 4\}$. If $\nu(x) = 1$ then $x \in \mathbb{Z}[\sqrt{d}]^*$ is a unit. And if $\nu(x) = 4$ then $\nu(y) = 1$ and hence $y \in \mathbb{Z}[\sqrt{d}]^*$ is a unit. It suffices to exclude the case $\nu(x) = 2$, that is assume $\nu(x) = 2$. As $d \leq -3$ we have $2 = \nu(x) = a^2 - db^2$. Thus in the case $b \neq 0$ we obtain $2 = a^2 - db^2 \geq 0 + 3 \cdot 1 = 3$ a contradiction. And in case $b = 0$ we get $2 = a^2$ for some $a \in \mathbb{Z}$, in contradiction to the irreducibility of 2 in $\mathbb{Z}$. Thus $\nu(x) = 2$ cannot occur and this means that $2 \in \mathbb{Z}[\sqrt{d}]$ is irreducible.

It remains to prove that $(\mathbb{Z}[\sqrt{d}], \nu)$ even is an Euclidean domain for $d \in \{-2, -1, 2, 3\}$. We consider the elements $0 \neq x = a + b\sqrt{d}$ and $y = f + g\sqrt{d} \in \mathbb{Z}[\sqrt{d}]$, then (as $\nu(y) \neq 0$) we may define

$$\begin{aligned} p &:= \frac{af - dbg}{a^2 - db^2} \\ q &:= \frac{ag - bf}{a^2 - db^2} \end{aligned}$$

That is $p + q\sqrt{d} := (1/(a^2 - db^2))y\overline{x}$. And therefore we obtain the identity $(p + q\sqrt{d})x = (1/(f^2 - dg^2))y\overline{x}x = y$. In other words we have found y/x to be $p + q\sqrt{d} \in \mathbb{Q}[\sqrt{d}]$. Now choose

$r, s \in \mathbb{Z}$ such that $|p-r|$ and $|q-s| \leq 1/2$ (which is possible, as the intervals $[r-1/2, r+1/2]$ (for $r \in \mathbb{Z}$) cover $\mathbb{Q}$) and define

$$\begin{aligned} u &:= r + s\sqrt{d} \\ v &:= y - ux \end{aligned}$$

Then it is clear that $u, v \in \mathbb{Z}[\sqrt{d}]$ and $y = ux + v$. But further we find

$$x\big((p-r) + (q-s)\sqrt{d}\big) = x\left(\frac{y}{x} - u\right) = y - ux = v$$

Due to the multiplicativity of ν (which even remains true for coefficients (here $p-r$ and $q-s$) in $\mathbb{Q}$) we find $\nu(v) = \nu(x)|(p-r)^2 - d(q-s)^2|$. But as $|d| \leq 3$ we can estimate

$$|(p-r)^2 - d(q-s)^2| \;\leq\; (p-r)^2 + |d|(q-s)^2 \;\leq\; (1/2)^2 + 3(1/2)^2 \;=\; 1$$

The case $|(p-r)^2 - d(q-s)^2| = 1$ can only occur if $|p-r| = |p-s| = 1/2$ and $d = 3$. But in this case we have $|(p-r)^2 - d(q-s)^2| = |1/4 - 3/4| = 1/2 < 1$. Thus we have even proved the strict estimate

$$\nu(v) \;=\; \nu(x)|(p-r)^2 - d(q-s)^2| \;<\; \nu(x)$$

Altogether we have seen that $\mathbb{Z}[\sqrt{d}]$ is an integral domain and that given $0 \neq x, y \in \mathbb{Z}[\sqrt{d}]$ we can find $u, v \in \mathbb{Z}[\sqrt{d}]$ such that $y = ux + v$ and $\nu(v) < \nu(x)$. But this is the condition to be an Euclidean domain.

□

Proof of (2.72):

- Without loss of generality we assume $\nu(a) \leq \nu(b)$ and let $f_1 := b$ and $f_2 := a$. That is if f and g are determined using the initialisation of the algorithm, then we get $f_1 = g$ and $f_2 = f$. Suppose we have already computed $f_1, \ldots, f_k \in R$ and $f_k \neq 0$, then in the next step the algorithm computes $q_k := q$ and $f_{k+1} := r \in R$ such that

$$f_{k-1} \;=\; q_k f_k + f_{k+1}$$

and $\nu(f_{k+1}) < \nu(f_k)$. Thus by induction on k we find the following strictly decreasing sequence of natural numbers

$$\nu(b) \;=\; \nu(f_1) \;\geq\; \nu(f_2) \;>\; \nu(f_3) \;>\; \ldots \;>\; \nu(f_k) \;>\; \nu(f_{k+1}) \;>\; \ldots$$

As $\nu(b)$ is finite this chain cannot decrease indefinitely but has to terminate at some level n. That is $f = f_{n+1} = 0$. And therefore $f_{n-1} = q_n g$ where $g = f_n$.

- We will now prove that for any $1 \leq k \leq n$ we have $g \mid f_k$. For $k = n$ we trivially have $g \mid g = f_n$. And for $k = n-1$ we have $f_{n-1} = q_n g$ by construction. Thus by induction we can assume $k \leq n-1$ and $g \mid f_n$ to $g \mid f_k$. Then from $f_{k-1} = q_k f_k + f_{k+1}$ it also is clear that $g \mid f_{k-1}$ completing the induction. In particular we have $g \mid f_2 = a$ and $g \mid f_1 = b$.

- Now suppose we are given some $d \in R$ with $d \mid a = f_2$ and $d \mid b = f_1$. Then we will prove that for any $k \in 1 \ldots n$ we get $d \mid f_n$ by induction on k. Thus assume $k \geq 2$ and $d \mid f_1$ to $d \mid f_k$. Then from $f_{k+1} = f_{k-1} + q_k f_k$ we also get $d \mid f_{k+1}$ completing the induction. In particular we get $d \mid f_n = g$. And hence g truly is the greatest common divisor of a and b.

- We will now prove the correctness of the refined Euclidean algorithm. The first part (the computation of g) is just a reformulation of the standard Euclidean algorithm. And as the second part is a finite computation, it is clear that the algorithm terminates. Next we will first prove that for any $2 \leq k \in \mathbb{N}$ we have $f_k = r_k f_2 + s_k f_1$. For $k = 2$ this is trivial $f_2 = 1 \cdot f_2 + 0 \cdot f_1 = r_2 f_2 + s_2 f_1$. And for $k \geq 3$ we have computed $q_k \in R$ such that $f_{k-1} = q_k f_k + f_{k+1}$ for some $f_{k+1} \in R$. In particular $f_3 = f_1 - q_2 f_2 = (-q_2) f_2 + 1 \cdot f_1 = r_3 f_2 + s_3 f_1$. Now we will use induction on k. That is we assume $f_{k-1} = r_{k-1} f_2 + s_{k-1} f_1$ and $f_k = r_k f_2 + s_k f_1$. Then a computation immediately yields

$$\begin{aligned} r_{k+1} f_2 + s_{k+1} f_1 &= (r_{k-1} - q_k r_k) f_2 + (s_{k-1} - q_k s_k) f_1 \\ &= (r_{k-1} f_2 + s_{k-1} f_1) - q_k (r_k f_2 + s_k f_1) \\ &= f_{k-1} - q_k f_k \;=\; f_{k+1} \end{aligned}$$

 In particular for $k = n$ we find $g = f_n = r_n f_2 + s_n f_1$. Thus let us distinguish the two cases. If $\nu(a) \leq \nu(b)$ we have $f_1 = b$, $f_2 = a$, $r = r_n$ and $s = s_n$. Thereby we get $g = r_n f_2 + s_n f_1 = ra + sb$. And conversely if $\nu(a) > \nu(b)$ then $f_1 = a$, $f_2 = b$, $r = s_n$ and $s = r_n$. Thereby we get $g = r_n f_2 + s_n f_1 = sb + ra$. Thus in any case we have obtained r and $s \in R$ such that $g = ra + sb$.

□

Proof of (2.76):

(i) We use induction on n to prove the statement. For $n = 0$ and any $a \in R_0 = R^*$ it is clear that $a \in R_1$, as for any $b \in R$ we may choose $r = 0$ and thereby get $a(ba^{-1}) = b$ such that $a \mid b - r$. Thus for $n \mapsto n + 1$ we are given $a \in R_n$ and any $b \in R$. That is we have $a \mid b - r$ for some $r \in R_{n-1}$. But by induction hypothesis we know $R_{n-1} \subseteq R_n$ and hence $r \in R_n$. But this again means $a \in R_{n+1}$ (as b has been arbitrary) which had to be proved.

(ii) We use induction on n again. For $n = 0$ we are given any $a \in R$ such that $\nu(a) \leq 0$. If $\nu(a) < 0$ then $\nu(a) = -\infty$ and hence $a = 0$. Otherwise $\nu(a) = 0$ and we use division with remainder to find some q, $r \in R$ such that $1 = qa + r$ and $\nu(r) < \nu(a) = 0$. But this can only be if $\nu(r) = -\infty$ which is $r = 0$. Hence we have $1 = qa$, that is $a \in R^* = R_0$ is a unit of R. In the induction step $n \mapsto n + 1$ we are given some $a \in R$ with $\nu(a) \leq n + 1$. Given $b \in R$ we use division with remainder to find q, $r \in R$ such that $b = qa + r$ and $\nu(r) < \nu(a) \leq n + 1$. Thus we have $\nu(r) \leq n$ and by induction hypothesis this yields $r \in R_n \cup \{0\}$. That is $a \mid b - r$ for some $r \in R_n \cup \{0\}$. And as b has been arbitrary this means $a \in R_{n+1}$, which had to be shown.

(iii) Clearly μ is well defined, as by assumption any $0 \neq a \in R$ is contained in some R_n. We need to prove that μ truly allows division with remainder: thus consider any $0 \neq a$ and $b \in R$, then we need to find q, $r \in R$ such that $b = qa + r$ and $\mu(r) < \mu(a)$. If $\mu(a) = 0$ then $a \in R_0 = R^*$ and hence we may choose $q := ba^{-1}$ and $r = 0$. If $\mu(a) \geq 1$ then we let $n := \mu(a) - 1 \in \mathbb{N}$. As $a \in R_{n+1}$ and $b \in R$ we have $a \mid b - r$ for some $r \in R_n \cup \{0\}$. This again yields $\mu(r) \leq n < n + 1 = \mu(a)$ and $b = qa + r$ for some $q \in R$, just what we wanted.

(iii) Next we want to prove $\mu(a) \leq \mu(ab)$. If $ab = 0$ then (as $b \neq 0$ and R is an itegral domain) we have $a = 0$. Thereby $\mu(a) = -\infty = \mu(ab)$. Thus assume $ab \neq 0$, and let $n := \mu(ab) \in \mathbb{N}$. If $n = 0$ then $ab \in R_0 = R^*$ and hence $a \in R^* = R_0$ (with $a^{-1} = b(ab)^{-1}$). Thus we likewise have $\mu(a) = 0 = \mu(ab)$. If now $n \geq 1$ then for any $c \in R$ there is some $r \in R_{n-1} \cup \{0\}$ such that $ab \mid c - r$. But as $a \mid ab$ this yields $a \mid c - r$, too and hence $a \in R_n$ again. Thereby $\mu(a) \leq n = \mu(ab)$.

(iii) If $a \in R^*$ then by (iii) above we have $\mu(b) \leq \mu(ab) \leq \mu(a^{-1}ab) = \mu(b)$ and hence $\mu(b) = \mu(ab)$. Conversely suppose $\mu(b) = \mu(ab)$. As $b \neq 0$ we also have $ab \neq 0$ (else $\mu(ab) = -\infty \neq \mu(b)$). Thus we may use division with remainder to find some q, $r \in R$ such that $b = q(ab) + r$ and $\mu(r) < \mu(b)$. Rearranging this equation we find $(1 - qa)b = r$. Now suppose we had $1 - qa \neq 0$, then by (iii) above again we had $\mu(b) \leq \mu((1 - qa)b) = \mu(r) < \mu(b)$, a contradiction. Thus we have $qa = 1$ and this means $a \in R^*$ as claimed.

(iv) If $R \setminus \{0\} = \bigcup_n R_n$ then (R, μ) is an Euclidean domain by (iii). Conversely suppose (R, ν) is an Euclidean domain for some Euclidean function ν. Now consider any $0 \neq a \in R$, and let $n := \nu(a)$. Then we have already seen in (ii) that $a \in R_n$ and hence we have $R \setminus \{0\} = \bigcup_n R_n$.

(v) As (R, ν) is an Euclidean domain we have $R \setminus \{0\} = \bigcup_n R_n$ by (iv). But by (iii) this implies that (R, μ) is an Euclidean domain, too. Thus consider any $a \in R$, if $a = 0$ then $\mu(a) = -\infty = \nu(a)$ by convention. Else let $n := \nu(a) \in \mathbb{N}$. Then $a \in R_n$ by (ii) and hence $\mu(a) \leq n = \nu(a)$ by construction of μ.

□

Proof of (2.79):
We will only prove parts (i), (ii) and (iii) here. Part (iv) requires the theory of Dedekind domains an will be postponed until then - see page (1118).

(i) Clearly $0 \trianglelefteq_{\mathfrak{i}} R$ is a prime ideal, as R is an integral domain (if $ab \in 0$ then $ab = 0$ and hence $a = 0$ or $b = 0$ such that $a \in 0$ or $b \in 0$ again). And further any maximal ideal is prime, because of (2.24). Conversely consider any non-zero prime ideal $0 \neq \mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$. As R is a PID there is some $p \in R$ such that $\mathfrak{p} = pR$. By (2.58.(ii)) this means that p is prime and due to (2.58.(v)) this implies that p is irreducible (as R is an integral domain). Now consider any ideal $\mathfrak{a}$ such that $\mathfrak{p} \subseteq \mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$. As R is a PID there is some $a \in R$ with $\mathfrak{a} = aR$ again. Now $p \in pR \subseteq aR$ means that there is some $b \in R$ such that $p = ab$. But p has been irreducible, that is $a \in R^*$ or $b \in R^*$. In the case $a \in R^*$ we have $\mathfrak{a} = aR = R$. And in the case $\mathfrak{b} \in R^*$ we have $a \approx b$ and hence $\mathfrak{a} = aR = pR = \mathfrak{p}$. As $\mathfrak{a}$ has been arbitrary this means that $\mathfrak{p}$ already is maximal.

(ii) As R is a PID every ideal $\mathfrak{a}$ of R is generated by *one* element $\mathfrak{a} = aR$. In particular any ideal $\mathfrak{a}$ is generated by *finitely many* elements. Thus R is notherian by property (c) in (2.34). We will now prove property (d) of UFDs. As R is noetherian property (1) in (2.60.(d)) is trivially satisfied by (ACC) of noetherian rings. Hence it suffices to check property (2) of (2.60.(d)). But as R is an integral domain any prime element $p \in R$ already is irreducible, due to (2.58.(ii)). This leaves

$$p \in R \text{ irreducible} \quad \Longrightarrow \quad p \in R \text{ prime}$$

Thus suppose $p \mid ab$ for some p, a and $b \in R$, say $pq = ab$. As R is a PID and $aR + pR \trianglelefteq_{\mathfrak{i}} R$ is an ideal we find some $d \in R$ such that $dR = aR + pR$. That is there are r, $s \in R$ such that $d = ar + ps$. And as $a \in aR + pR = dR$ there is some $f \in R$ with $a = df$. Likewise we find some $g \in R$ with $p = dg$. But as p is irreducible we have $g \in R^*$ or $d \in R^*$. If $g \in R^*$ then we get $p \mid a$ from

$$p(fg^{-1}) \;=\; (g^{-1}p)f \;=\; df \;=\; a$$

And if $d \in R^*$ we get $p \mid b$ by the equalities below. Thus we have found $p \mid a$ or $p \mid b$ which means that p is prime

$$\begin{aligned} p(d^{-1}qr + d^{-1}bs) \;&=\; d^{-1}(pqr + pbs) \;=\; d^{-1}(abr + pbs) \\ &=\; bd^{-1}(ar + ps) \;=\; bd^{-1}d \;=\; b \end{aligned}$$

(iii) If $\mathfrak{a} = 0$ then $\mathfrak{a} = 0R$ is a principal ideal (generated by $0 \in R$). And if $\mathfrak{a} \neq 0$ there is some $0 \neq b \in \mathfrak{b}$. Therefore we may choose a as given in the claim of (iii). Now consider any $b \in \mathfrak{a}$ and choose q, $r \in R$ such that $b = qa + r$ and $\nu(r) < \nu(a)$. Then $r = b - qa \in \mathfrak{a}$ (as a, $b \in \mathfrak{a}$). But a has minimal value $\nu(a)$ among all those $b \in \mathfrak{a}$ with $b \neq 0$. Therefore $r \in \mathfrak{a}$ and $\nu(r) < \nu(a)$ implies $r = 0$. Thus $b = qa \in aR$, and as b has been arbitrary this means $\mathfrak{a} \subseteq aR$. And as $a \in R$ we have $aR \subseteq \mathfrak{a}$. Together we find that $\mathfrak{a} = aR$ is a principal ideal. And as $\mathfrak{a}$ has been arbitrary this means that R is a PID.

□

Proof of (2.80):

- Let us prove this statement by induction on n, starting with $n = 1$. Clearly $\mathfrak{m} := tF[t] \trianglelefteq_{\mathfrak{i}} F[t]$ is a maximal ideal, as $F[t]/\mathfrak{m} \xrightarrow{\sim} F$ are isomorphic under $f + \mathfrak{m} \mapsto f(0)$. Thus $F[t]/\mathfrak{m}$ is a field and thereby $\mathfrak{m}$ a maximal ideal. Thus $F[t]$ has at least one maximal ideal.

- Suppose $F[t]$ only had finitely many ideals, say $\mathrm{Smax}(F[t]) = \{\, \mathfrak{m}_1, \ldots, \mathfrak{m}_n \,\}$ are all of them. By (2.79.(iii)) $F[t]$ is a PID, as it is an Euclidean domain under the degree function. So any $\mathfrak{m}_i$ is generated by a single element $\mathfrak{m}_i = p_i F[t]$. As any maximal ideal $\mathfrak{m}_i$ is prime, the p_i are prime elements of $F[t]$. Now define

$$g \;:=\; p_1 \ldots p_n + 1 \;\in\; F[t]$$

As p_i is prime it is non-zero and not a unit. As $F[t]^* = F^*$ together this means $\deg(p_i) \geq 1$, and therefore $\deg(g) = \deg(p_1) + \cdots + \deg(p_n) \geq 1$. In particular $g \in F[t] \setminus F$ is non-zero and not a unit. As $F[t]$ is a PID and therefore an UFD, g admits a prime divisor, i.e. there is a prime element $p \in F[t]$ with $p \mid g$. That is there is some $h \in F[t]$ with $ph = g = p_1 \ldots p_n + 1$. Suppose we had $p = ap_1$ for some $a \in F^*$, then $ap_1 h = ph = p_1 \ldots p_n + 1$ such that $p_1(ah - p_2 \ldots p_n) = 1$. This would mean $p_1 \in F[t]^*$ in contradiction to p_1 being a prime element. Therefore p is not associate to p_1 and similarly not to any of the p_i. That is $pF[t]$ is an ideal, different from $\mathfrak{m}_1$ to $\mathfrak{m}_n$. But p is a prime element and hence $pF[t]$ is a non-zero prime ideal. By (2.79.(i)) this means $pF[t]$ is a maximal ideal. But this contradicts $\{\, \mathfrak{m}_1, \ldots, \mathfrak{m}_n \,\}$ to be a complete list of maximal ideals of $F[t]$. Therefore $F[t]$ has infinitely many maximal ideals.

- Now for the induction step: By induction hypothesis we know that $R := F[t_1, \ldots, t_n]$ has finitely many maximal ideals. We have to check that $F[t_1, \ldots, t_{n+1}] = R[t_{n+1}]$ has infinitely many prime ideals, as well. Let us abbreviate $t := t_{n+1}$, and pick up any maximal ideal in R. Then

$$\widetilde{\mathfrak{m}} \;:=\; \mathfrak{m} + tR[t] \;=\; \{\, f \in R[t] \mid f(0) \in \mathfrak{m} \,\}$$

gives rise to an isomorphism $R[t]/\widetilde{\mathfrak{m}} \xrightarrow{\sim} R/\mathfrak{m}$ of R-algebras, according to (3.43.(iv)). But $R/\mathfrak{m}$ is a field, as $\mathfrak{m}$ is a maximal ideal and thereby $R[t]/\widetilde{\mathfrak{m}}$ is a field, which means $\widetilde{\mathfrak{m}} \trianglelefteq_{\mathrm{i}} R[t]$ is a maximal ideal. These ideals are pairwise distinct: If $\mathfrak{m}$ and $\mathfrak{n} \trianglelefteq_{\mathrm{i}} R$ are maximal ideals with $\widetilde{\mathfrak{m}} = \widetilde{\mathfrak{n}}$, then we get $\mathfrak{m} = \widetilde{\mathfrak{m}} \cap R = \widetilde{\mathfrak{n}} \cap R = \mathfrak{n}$. Thus we have an injective map

$$\mathrm{Smax}(R) \;\hookrightarrow\; \mathrm{Smax}(R[t]) \;:\; \mathfrak{m} \mapsto \widetilde{\mathfrak{m}}$$

That is $F[t_1, \ldots, t_{n+1}] = R[t]$ has as least as many maximal ideals, as $R = F[t_1, \ldots, t_n]$. In particular, as $\mathrm{Smax}(R)$ is infinite by induction hypothesis, $\mathrm{Smax}(R[t])$ is infinite, as well.

□

Proof of (2.82):

(i) As R is an UFD by (2.79.(ii)) the length $\ell(a) \in \mathbb{N}$ of $0 \neq a \in R$ is well defined, due to (2.60.(b)). Therefore $\delta : R \to \mathbb{N}$ is a well-defined function and it is clear that it satisfies properties (1) and (2). Thus consider any $0 \neq a, b \in R$, as R is a PID we may choose some $r \in R$ such that $rR = aR + bR$. It is clear that $r \neq 0$, as $0 \neq a \in rR$. Now suppose $b \notin aR$, Then it is clear that $r \in aR + bR$ and it remains to prove $\delta(r) < \delta(a)$. As $a \in aR + bR = rR$ there is some $s \in R$ such that $a = rs$. Suppose $s \in R^*$, then $a \approx r$ and hence $aR = rR$. But $b \in aR + bR = rR = aR$ is a contradiction to $b \notin aR$. Thus $s \notin R^*$ which means $\ell(s) \geq 1$. Hence we have $\delta(s) \geq 2$ and as $\delta(r) > 0$ (recall $r \neq 0$) this finally is

$$\delta(r) \;<\; 2\delta(r) \;\leq\; \delta(r)\delta(s) \;=\; \delta(rs) \;=\; \delta(a)$$

(ii) As $\mathfrak{a} \neq 0$ there is some $0 \neq b \in \mathfrak{a}$. And hence we may choose $a \in \mathfrak{a}$ as given in the claim of (ii). We now want to verify $\mathfrak{a} = aR$, as $a \in \mathfrak{a}$ the inclusion $aR \subseteq \mathfrak{a}$ is clear. Conversely choose any $0 \neq b \in \mathfrak{a}$ ($0 \in aR$ is clear). If we had $b \notin aR$, then by property (3) there would be some $r \in aR + bR$ such that $\delta(r) < \delta(a)$. But as $a, b \in \mathfrak{a}$ we have $aR + bR \subseteq \mathfrak{a}$ and hence $r \in \mathfrak{a}$. As a has been chosen to have minimal value $\delta(a)$ this only leaves $r = 0$ and hence $0 \neq a \in aR + bR = rR = 0$, a contradiction. Thus we have $b \in aR$ and hence $\mathfrak{a} \subseteq aR$ as well.

(iii) By construction of δ it is clear that $\delta : R \to \mathbb{N}$ and that δ satisfies (2). It remains to verify (3), thus consider any $0 \neq a, b \in R$ then we choose $q, r \in R$ such that $b = qa + r$ and $\nu(r) < \nu(a)$. If $r = 0$ then $b = qa \in aR$. And if $r \neq 0$ we have $r = -qa + b \in aR + bR$ and $\delta(r) = \nu(r) + 1 < \nu(a) + 1 = \delta(a)$.

□

Proof of (2.83):

(i) First suppose $mR = \bigcap_a aR$, in particular $mR \subseteq aR$ for any $a \in R$. But this is $a \mid m$ for any $a \in A$ and hence $A \mid m$. Now consider any $n \in R$ such that $A \mid n$, that is $a \mid n$ and hence $n \in aR$

for any $a \in A$. Therfore $n \in \bigcap_a aR = mR$ and hence $m \mid n$. Thus we have proved $m \in \operatorname{lcm}(A)$. Conversely suppose $m \in \operatorname{lcm}(A)$, then $A \mid m$ and hence $m \in \bigcap_a aR$ again. In particular we have $mR \subseteq \bigcap_a aR$. Now consider any $n \in \bigcap_a aR$, then $A \mid n$ again and hence $m \mid n$ by assumption on m. Thus we have $n \in mR$ and as n has been arbitrary this is the converse inclusion $\bigcap_a aR \subseteq mR$.

(ii) Let $dR = \sum_a aR$ then for any $a \in A$ we have $aR \subseteq dR$ and hence $d \mid a$. Thus we found $d \mid A$, as a has been arbitrary. Now consider some $c \in R$ such that $c \mid A$. That is for any $a \in A$ we get $c \mid a$ and hence $aR \subseteq cR$. But from this we get $dR = \sum_a aR \subseteq cR$ which also is $c \mid d$. Together we have proved $d \in \gcd(A)$ again.

(iii) Now assume that R is a PID, then we will also prove the converse implication. By assumption on R there is some $g \in R$ such that $gR = \sum_a aR$ and by (ii) this means $g \in \gcd(A)$. Now from (2.58.(viii)) and d, $g \in \gcd(A)$ we get $d \approx g$ and hence $dR = gR = \sum_a aR$.

(iv) For $n = 1$ the statement is trivial for $b_1 := b$, thus let us assume $n \geq 2$. Then we denote $a := a_1 \dots a_n$ and $\widehat{a}_i := a/a_i \in R$. Now consider $d \in \gcd\{\widehat{a}_1, \dots, \widehat{a}_n\}$ and suppose we had $d \notin R^*$. Then (as R is an UFD) there would be a prime element $p \in R$ dividing $p \mid d$. Thus we had $p \mid d \mid \widehat{a}_1$ and hence (as p is prime) there would be some $i \in 2 \dots n$ such that $p \mid a_i$. Likewise for i we have $p \mid d \mid \widehat{a}_i$ and hence $p \mid a_j$ for some $j \neq i$. But a_i and a_j are relatively prime by assupmtion, a contradiction. Thus we have $d \in R^*$, that is $1 \in \gcd\{\widehat{a}_1, \dots, \widehat{a}_n\}$. And by (iii) this means that there are some $h_1, \dots, h_n \in R$ such that $1 = h_1\widehat{a}_1 + \dots + h_n\widehat{a}_n$. Now let $b_i := bh_i$, then the claim is immediate from

$$\sum_{i=1}^{n} \frac{b_i}{a_i} \;=\; \sum_{i=1}^{n} \frac{bh_i\widehat{a}_i}{a} \;=\; \frac{b}{a} \sum_{i=1}^{n} h_i\widehat{a}_i \;=\; \frac{b}{a}$$

□

Proof of (2.84):

- (a) $\implies$ (b): consider $a, b \in R$, by assumption there are $r, s \in R$ such that $d = ra + sb \in \gcd(a, b)$. By construction we have $d \in aR + bR$ and hence $dR \subseteq aR + bR$. On the other hand we have $d \in \gcd(a, b)$ and hence $d \mid a$ and $d \mid b$. But that is $aR \subseteq dR$ and $bR \subseteq dR$ such that $aR + bR \subseteq dR$ as well. Together that is $dR = aR + bR$.

- (b) $\implies$ (c): $\mathfrak{a}$ being finitely generated means that there are some $a_1, \dots, a_n \in R$ such that $\mathfrak{a} = a_1R + \dots + a_nR$. We will now use induction on n to prove that $\mathfrak{a}$ is principal. In the case $n = 0$ we have $\mathfrak{a} = 0 = 0R$ and in the case $n = 1$ trivially $\mathfrak{a} = a_1R$ is principal. Thus we may assume $n \geq 2$. Then by induction hypothesis $\mathfrak{u} := a_1R + \dots + a_{n-1}R \trianglelefteq_{\mathrm{i}} R$ is principal, that is there is some $u \in R$ such that $\mathfrak{u} = uR$. Now $\mathfrak{a} = a_1R + \dots + a_nR = \mathfrak{u} + a_nR = uR + a_nR$. Thus by assumption (b) there is some $d \in R$ such that $\mathfrak{a} = dR$ is principal.

- (c) $\implies$ (a): consider any $a, b \in R$ and let $\mathfrak{a} := aR + bR$. By construction $\mathfrak{a}$ is finitely generated and hence there is some $d \in R$ such that $\mathfrak{a} = dR$. Now $d \in aR + bR$ means that there are some r, $s \in R$ such that $d = ra + sb$. And by (2.83.(ii)) $dR = aR + bR$ yields that $ra + sb = d \in \gcd(a, b)$ as well.

□

Proof of (2.85):

- (a) $\implies$ (b) and (c): if R is a PID then R is a noetherian UFD due to (2.79.(ii)). And it is clear that R also is a Bezout domain (e.g. by property (c) in (2.84)).
- (c) $\implies$ (a): consider any ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$, as R is noetherian $\mathfrak{a}$ is finitely generated, due to property (c) of noetherian rings (2.34). And due to poroperty (c) of Bezout domains (2.84) this means that $\mathfrak{a}$ is principal. As a Bezout domain also is an integral domain this means that R is a PID.
- (b) $\implies$ (a): consider any ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$. If $\mathfrak{a} = 0$ then $\mathfrak{a} = 0R$ trivially is principal. Thus we assume $\mathfrak{a} \neq 0$ and choose any $0 \neq a \in R$ with

 $$\ell(a) \;=\; \min\{\, \ell(b) \mid 0 \neq b \in \mathfrak{a} \,\}$$

 where $\ell(a)$ is the number of prime factors of a, that is $\ell(a) = k$, where $a = p_1 \dots p_k$ for some prime elements $p_i \in R$. As $a \in \mathfrak{a}$ we have $aR \subseteq \mathfrak{a}$. Conversely consider any $0 \neq b \in \mathfrak{a}$. As R is a Bezout domain the ideal $aR + bR$ is principal $aR + bR = dR$ for some $d \in R$, due to property (b) in (2.84). As $a, b \in \mathfrak{a}$ we have $d \in aR + bR \subseteq \mathfrak{a}$ and clearly $d \neq 0$ (as $a \neq 0$). Thus by construction of a we have $\ell(a) \leq \ell(d)$. But on the other hand we have $a \in aR + bR = dR$ and hence $d \mid a$ which implies $\ell(d) \leq \ell(a)$ by (2.64.(iii)). But from $d \mid a$ and $\ell(a) = \ell(d)$ we get $a \approx d$ by choosing prime decompositions of a and d as in (2.64.(iv)). Therefore we have $b \in aR + bR = dR = aR$. This proves $b \in aR$ and hence $\mathfrak{a} \subseteq aR$, as b has been arbitrary ($b = 0$ is clear). Altogether we have $\mathfrak{a} = aR$ is principal and hence R is a PID, as $\mathfrak{a}$ has been arbitrary.

□

Proof of (2.88):

- (a) $\implies$ (b): consider $a + \mathfrak{a} \in \mathrm{zd}(R/\mathfrak{a})$, that is $a \in \mathrm{zd}_R(R/\mathfrak{a})$, then by assumption we have $a \in \sqrt{\mathfrak{a}}$. That is $a^k \in \mathfrak{a}$ for some $k \in \mathbb{N}$ and hence $(a + \mathfrak{a})^k = a^k + \mathfrak{a} = 0 + \mathfrak{a}$ such that $a + \mathfrak{a}$ is a nilpotent of $R/\mathfrak{a}$.
- (b) $\implies$ (c): the nil-radical of $R/\mathfrak{a}$ is trivially included in the set of zero-divisors of $R/\mathfrak{a}$ due to (1.47.(ii)), which implies equality.
- (c) $\implies$ (a): consider $a \in \mathrm{zd}_R(R/\mathfrak{a})$, that is $a + \mathfrak{a} \in \mathrm{zd}(R/\mathfrak{a})$. Then by assumption $a + \mathfrak{a}$ is a nilpotent of $R/\mathfrak{a}$, that is $a^k + \mathfrak{a} = (a + \mathfrak{a})^k = 0 + \mathfrak{a}$ for some $k \in \mathbb{N}$. But this again means $a^k \in \mathfrak{a}$ and hence $a \in \sqrt{\mathfrak{a}}$.
- (c) $\implies$ (d): consider $a, b \in R$ such that $ab \in \mathfrak{a}$ but $b \notin \mathfrak{a}$. That is $(a + \mathfrak{a})(b + \mathfrak{a}) = ab + \mathfrak{a} = 0 + \mathfrak{a}$ and as $b + \mathfrak{a} \neq 0 + \mathfrak{a}$ this means that $a + \mathfrak{a} \in \mathrm{zd}(R/\mathfrak{a})$ is a zero-divisor of $R/\mathfrak{a}$. By assumption this means that $a + \mathfrak{a}$ is a nilpotent of $R/\mathfrak{a}$ and hence $a^k + \mathfrak{a} = (a + \mathfrak{a})^k = 0 + \mathfrak{a}$ for some $k \in \mathbb{N}$. But this again is $a^k \in \mathfrak{a}$ and hence $a \in \sqrt{\mathfrak{a}}$.
- (d) $\implies$ (b): consider $a + \mathfrak{a} \in \mathrm{zd}R/\mathfrak{a}$ that is there is some $0 + \mathfrak{a} \neq b + \mathfrak{a} \in R/\mathfrak{a}$ such that $ab + \mathfrak{a} = (a + \mathfrak{a})(b + \mathfrak{a}) = 0 + \mathfrak{a}$. But this means $ab \in \mathfrak{a}$ and as also $b \notin \mathfrak{a}$ we find $a \in \sqrt{\mathfrak{a}}$ by assumption. That is $a^k \in \mathfrak{a}$ for some $k \in \mathbb{N}$ and hence $(a + \mathfrak{a})^k = a^k + \mathfrak{a} = 0 + \mathfrak{a}$ such that $a + \mathfrak{a}$ is a nilpotent of $R/\mathfrak{a}$.

- The equivalence (d) $\iff$ (e) is finally true by elementary logical operations (note that we may commute the quantifiers $\forall\, a$ and $\forall\, b$)

$$\begin{aligned}
\text{(d)} &\iff \forall\, a,b \in R \,:\, \neg\Big((ab \in \mathfrak{a}) \wedge (b \notin \mathfrak{a})\Big) \vee (a \in \sqrt{\mathfrak{a}}) \\
&\iff \forall\, a,b \in R \,:\, (ab \notin \mathfrak{a}) \vee (b \in \mathfrak{a}) \vee (a \in \sqrt{\mathfrak{a}}) \\
&\iff \forall\, b,a \in R \,:\, (ba \notin \mathfrak{a}) \vee (a \in \mathfrak{a}) \vee (b \in \sqrt{\mathfrak{a}}) \\
&\iff \forall\, a,b \in R \,:\, (ab \notin \mathfrak{a}) \vee (b \in \sqrt{\mathfrak{a}}) \vee (a \in \mathfrak{a}) \\
&\iff \forall\, a,b \in R \,:\, \neg\Big((ab \in \mathfrak{a}) \wedge (b \notin \sqrt{\mathfrak{a}})\Big) \vee (a \in \mathfrak{a}) \\
&\iff \text{(e)}
\end{aligned}$$

□

Proof of (2.90):
We will only prove statements (i) to (vii) here. Statement (viii) is concerned with localizations and requires the correspondence theorem of ideals in localizations. Its proof is hence postponed until we have shown this theorem. Hence it can be found on page (1102).

(i) If $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ is prime and we assume $ab \in \mathfrak{p}$ for some a, $b \in R$, then $a \notin \mathfrak{p}$ or $b \in \mathfrak{p}$. Thus if also $b \notin \mathfrak{p}$ then necessarily $a \in \mathfrak{p} \subseteq \sqrt{\mathfrak{p}}$. Thus $\mathfrak{p}$ is primary, by property (d) in (2.88).

(ii) Let $\mathfrak{p} := \sqrt{\mathfrak{a}}$, then $\mathfrak{p}$ is an ideal of R, due to (2.22.(ii)). Now assume $1 \in \mathfrak{p}$, then there would be some $k \in \mathbb{N}$ such that $1 = 1^k \in \mathfrak{a}$. That is $1 \in \mathfrak{a}$ and hence $\mathfrak{a} = R$ in contradiction to $\mathfrak{a}$ being a primary ideal. Now assume $ab \in \mathfrak{p}$ for some a, $b \in R$. That is there is some $k \in \mathbb{N}$ such that $(ab)^k = a^k b^k \in \mathfrak{a}$. If we have $b^k \in \sqrt{\mathfrak{a}} = \mathfrak{p}$ then $b \in \mathfrak{p}$, as $\mathfrak{p}$ is a radical ideal. Thus assume $b^k \notin \sqrt{\mathfrak{a}}$. Then by property (e) we get $a^k \in \mathfrak{a}$ and hence $a \in \mathfrak{p}$. Thus $\mathfrak{p}$ is a prime ideal.

(ii) It remains to prove that $\mathfrak{p} = \sqrt{\mathfrak{a}}$ is the uniquely determined minimal prime ideal containing $\mathfrak{a}$. Thus assume $\mathfrak{a} \subseteq \mathfrak{q} \trianglelefteq_{\mathfrak{i}} R$ is any prime ideal containing $\mathfrak{a}$. Then we have $\mathfrak{p} = \sqrt{\mathfrak{a}} \subseteq \sqrt{\mathfrak{q}} = \mathfrak{q}$. Thus if $\mathfrak{q} \subseteq \mathfrak{p}$, then $\mathfrak{p} = \mathfrak{q}$, such that $\mathfrak{p}$ is a minimal prime ideal containing $\mathfrak{a}$. And if $\mathfrak{p}_*$ is minimal then $\mathfrak{p} \subseteq \mathfrak{p}_*$ again and hence $\mathfrak{p}_* = \mathfrak{p}$, due to minimality. Thus $\mathfrak{p}$ also is uniquely determined.

(iii) Let $\mathfrak{m} := \sqrt{\mathfrak{a}}$ and assume that $\mathfrak{m}$ is maximal. Now consider any a, $b \in R$ such that $ab \in \mathfrak{a}$ but $b \notin \mathfrak{a}$. Then we have to prove $a \in \mathfrak{m}$ (in order to satisfy property (d) of primary ideals). Thus suppose $a \notin \mathfrak{m}$, then (because of the maximality of $\mathfrak{m}$) we had $R = \mathfrak{m} + aR$. That is there would be some $h \in R$ such that $1 - ah \in \mathfrak{m}$. And by definition of $\mathfrak{m}$ this is $(1-ah)^k \in \mathfrak{a}$ for some $k \in \mathbb{N}$. Now define

$$f \;:=\; -\sum_{i=1}^{k} (-1)^i \binom{k}{i} \frac{(ah)^i}{a} \;\in\; R$$

Then using the binomial rule we find $1 - af = (1-ah)^k \in \mathfrak{a}$ by a straightforward computation. That is $af + \mathfrak{a} = 1 + \mathfrak{a}$ and hence $0 + \mathfrak{a} = (f+\mathfrak{a})(0+\mathfrak{a}) = (f+\mathfrak{a})(ab+\mathfrak{a}) = (fa+\mathfrak{a})(b+\mathfrak{a}) = (1+\mathfrak{a})(b+\mathfrak{a}) = b + \mathfrak{a}$. That is $b \in \mathfrak{a}$ in contradiction to the assumption. Thus we have $a \in \mathfrak{m}$, which we had to prove.

(iv) From the assumption we get $\mathfrak{m} = \sqrt{\mathfrak{m}} = \sqrt{\mathfrak{m}^k} \subseteq \sqrt{\mathfrak{a}} \subseteq \sqrt{\mathfrak{m}} = \mathfrak{m}$ due to (2.22.(vi)) (and as any maximal ideal is prime and hence radical). Thus we have $\sqrt{\mathfrak{a}} = \mathfrak{m}$ and hence $\mathfrak{a}$ is a primary ideal by (iii).

(v) Denote $\mathfrak{a} := \mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_k$, then we first note that according to (2.25.(v))

$$\sqrt{\mathfrak{a}} \;=\; \sqrt{\bigcap_{i=1}^{k} \mathfrak{a}_i} \;=\; \bigcap_{i=1}^{k} \sqrt{\mathfrak{a}_i} \;=\; \bigcap_{i=1}^{k} \mathfrak{p} \;=\; \mathfrak{p}$$

Now consider any $a, b \in R$ such that $b \notin \mathfrak{a}$. That is there is some $i \in 1 \ldots k$ such that $b \notin \mathfrak{a}_i$. But as $ab \in \mathfrak{a} \subseteq \mathfrak{a}_i$ and $\mathfrak{a}_i$ is primary we find $a \in \sqrt{\mathfrak{a}_i} = \mathfrak{p} = \sqrt{\mathfrak{a}}$. That is $\mathfrak{a}$ satisfies property (d) in (2.88).

(vi) Recall that $\mathfrak{a} : u = \{\, b \in R \mid bu \in \mathfrak{a} \,\}$. (1) Hence if $u \in \mathfrak{a}$ and $b \in R$, then $bu \in \mathfrak{a}$, too, since $\mathfrak{a}$ is an ideal. But this already means $b \in \mathfrak{a} : u$. (3) In this case we have $u \notin \mathfrak{p} = \sqrt{\mathfrak{a}}$. If $b \in \mathfrak{a} : u$ then $bu \in \mathfrak{a}$ and since $\mathfrak{a}$ is primary together these imply $b \in \mathfrak{a}$. Hence we have $\mathfrak{a} : u \subseteq \mathfrak{a}$. Conversely, if $b \in \mathfrak{a}$, then $bu \in \mathfrak{a}$ is trivial, as $\mathfrak{a}$ is an ideal and hence we have $b \in \mathfrak{a} : u$, such that $\mathfrak{a} \subseteq \mathfrak{a} : u$, as well. (2) We now have $u \notin \mathfrak{a}$. Consider any $b \in \sqrt{\mathfrak{a} : u}$, that is there is some $k \in \mathbb{N}$ such that $b^k u \in \mathfrak{a}$. As $u \notin \mathfrak{a}$ and $\mathfrak{a}$ is primary, we find $b^k \in \sqrt{\mathfrak{a}}$ and hence $b \in \sqrt{\mathfrak{a}} = \mathfrak{p}$, as $\sqrt{\mathfrak{a}}$ is a radical ideal. That is we have proved $\sqrt{\mathfrak{a} : u} \subseteq \mathfrak{p}$, but as $\mathfrak{a} \subseteq \mathfrak{a} : u$ the converse inclusion is clear from $\mathfrak{p} = \sqrt{\mathfrak{a}} \subseteq \sqrt{\mathfrak{a} : u}$. Thus we have $\sqrt{\mathfrak{a} : u} = \mathfrak{p}$. Now consider any $a, b \in R$ such that $ab \in \mathfrak{a} : u$ but $b \notin \mathfrak{a} : u$. This means $abu \in \mathfrak{a}$ but $bu \notin \mathfrak{a}$. As $\mathfrak{a}$ is primary we again find $a \in \sqrt{\mathfrak{a}} = \mathfrak{p} = \sqrt{\mathfrak{a} : u}$ and hence $\mathfrak{a} : u$ is primary, as well.

(vii) First observe that the radical of $\mathfrak{a}$ is truly given to be $\mathfrak{p}$, as we compute

$$\begin{aligned}
\sqrt{\mathfrak{a}} \;&=\; \left\{ a \in R \;\middle|\; \exists\, k \in \mathbb{N} \;:\; a^k \in \mathfrak{a} = \varphi^{-1}(\mathfrak{b}) \right\} \\
&=\; \left\{ a \in R \;\middle|\; \exists\, k \in \mathbb{N} \;:\; \varphi(a)^k = \varphi(a^k) \in \mathfrak{p} \right\} \\
&=\; \left\{ a \in R \;\middle|\; \exists\, \varphi(a) \in \sqrt{\mathfrak{b}} = \mathfrak{q} \right\} \;=\; \varphi^{-1}(\mathfrak{q}) \;=\; \mathfrak{p}
\end{aligned}$$

Thus consider $a, b \in R$ sucht that $ab \in \mathfrak{a}$ but $b \notin \mathfrak{a}$, that is $\varphi(a)\varphi(b) = \varphi(ab) \in \mathfrak{b}$ but $\varphi(b) \notin \mathfrak{b}$. As $\mathfrak{b}$ is primary this yields $\varphi(a) \in \sqrt{\mathfrak{b}} = \mathfrak{q}$ and hence $a \in \varphi^{-1}(\mathfrak{q}) = \sqrt{\mathfrak{a}}$. That is $\mathfrak{a}$ is primary again.

□

Proof of (2.91):

(i) Let us denote $\mathfrak{p} := pR$, then $\mathfrak{p}$ is a prime ideal, as p is a prime element. Also we have $\mathfrak{p}^n = p^n R = \mathfrak{a}$ and hence $\sqrt{\mathfrak{a}} = \sqrt{\mathfrak{p}^n} = \sqrt{\mathfrak{p}} = \mathfrak{p}$. That is $\mathfrak{a}$ is associated to $\mathfrak{p}$. We will now prove, that $\mathfrak{a}$ is primary, by using induction on n. For $n = 1$ we have $\mathfrak{a} = pR = \mathfrak{p}$, that is $\mathfrak{a}$ is prime and hence primary by (2.90.(i)). Now consider any $n \geq 2$, and $a, b \in R$ such that $ab \in \mathfrak{a}$ but $b \notin \sqrt{\mathfrak{a}} = \mathfrak{p}$. That is there is some $h \in R$ such that $ab = p^n b$ but $p \not| b$. As p is prime, $p \mid hp^n = ab$ and $p \not| b$ we have $p \mid a$, that is there is some $\alpha \in R$ such that $a = \alpha p$. As R is an integral domain we get $\alpha b = (ab)/p = (p^n h)/p = p^{n-1} h$. Now from $ab \in p^{n-1}R$ and $b \notin \sqrt{p^{n-1}R} = \mathfrak{p}$ the induction hypothesis yields $\alpha \in p^{n-1}R$ and therefore $a = \alpha p \in p^n R = \mathfrak{a}$, that is $\mathfrak{a}$ is primary.

(ii) If $\mathfrak{a} = 0$ then $\mathfrak{a}$ is prime (as R is an integral domain) and hence primary (by (2.90.(i))). And if $\mathfrak{a} = p^n R$ for some prime element $p \in R$ and $1 \leq n \in \mathbb{N}$, then $\mathfrak{a}$ is primary, as we have seen in (i). Conversely consider any primary ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$. As R is a PID it is generated by a single element

$\mathfrak{a} = aR$. Clearly $a \notin R^*$ (as else $\mathfrak{a} = R$ would not be primary). If $a = 0$ then $\mathfrak{a} = 0$ and hence there is nothing to prove. Thus assume $a \neq 0$, recall that R is an UFD by (2.79) and assume there would be two non-associate prime elements $p, q \in R$ such that $p \mid a$ and $q \mid a$. Then we let $m := \langle a \mid p \rangle$ and $n := \langle a \mid q \rangle$ (clearly $1 \leq m, n \in \mathbb{N}$ by (2.64.(iv))) and thereby get $p^m q^m \mid a$. That is there is some $b \in R$ such that $p^m q^n b = a$ and $p \nmid b$ and $q \nmid b$. It is clear that $p^m \notin \sqrt{\mathfrak{a}}$ as else there would be some $k \in \mathbb{N}$ such that $q \mid a \mid p^{mk}$. On the other hand we have $q^n b \notin \mathfrak{a}$, as else $p \mid a \mid q^n b$. This contradicts $\mathfrak{a}$ being a primary ideal and hence there is only one prime element $p \in R$ (up to associatedness) dividing a. Thus $a = \alpha p^m$ for some $\alpha \in R^*$ and this finally means $\mathfrak{a} = aR = p^n R$.

(iii) First of all $\mathfrak{m} = \langle s, t \rangle_{\mathrm{i}}$ is a maximal ideal, as $R/\mathfrak{m}$ is a field (in fact we find $R/\mathfrak{m} \cong_{\mathrm{r}} E : f + \mathfrak{m} \mapsto f(0,0)$). Further we have $\mathfrak{a} = \langle s, t^2 \rangle_{\mathrm{i}} \subseteq \langle s, t \rangle_{\mathrm{i}} = \mathfrak{m}$. It is even true that $t \notin \mathfrak{a}$ and hence $\mathfrak{a} \subset \mathfrak{m}$ (suppose $t = fs + gt^2$ for some $f, g \in R$. Then letting $t = 0$ we would find $0 = fs$ and hence $f = 0$. But this yields $1 = gt$ a contradiction to $t \notin R^*$). Next we have $\mathfrak{m} = \langle s^2, st, t^2 \rangle_{\mathrm{i}} \subseteq \langle s, t^2 \rangle_{\mathrm{i}} = \mathfrak{a}$. And in analogy to the above we find $s \notin \mathfrak{m}^2$, altogether this means

$$\mathfrak{m}^2 \subset \mathfrak{a} \subset \mathfrak{m}$$

As $\mathfrak{m}$ is maximal (2.90.(iv)) yields that $\mathfrak{a}$ is primary and associated to $\mathfrak{m}$. Now suppose there would be some $k \in \mathbb{N}$ and $\mathfrak{p} \in \operatorname{Spec}(R)$ such that $\mathfrak{a} = \mathfrak{p}^k$. Then from $\mathfrak{m}^2 \subseteq \mathfrak{a} = \mathfrak{p}^k \subseteq \mathfrak{m}$ we would get $\mathfrak{m} = \sqrt{\mathfrak{m}^2} \subseteq \mathfrak{p} = \sqrt{\mathfrak{p}^k} \subseteq \sqrt{\mathfrak{m}} = \mathfrak{m}$. That is $\mathfrak{p} = \mathfrak{m}$ and hence $\mathfrak{m}^2 \subset \mathfrak{a} = \mathfrak{m}^k \subset \mathfrak{m}$. If $k \leq 1$ then we have $\mathfrak{m}^k \supseteq \mathfrak{m}$ a contradiction. And if $k \geq 2$ then $\mathfrak{m}^2 \supseteq \mathfrak{m}^k$ a contradiction, too. Thus there is no prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ and $k \in \mathbb{N}$ with $\mathfrak{a} = \mathfrak{p}^k$.

(iv) First of all it is clear that $\mathfrak{u} = \langle u^2 - st \rangle_{\mathrm{i}} \subseteq \langle t, u \rangle_{\mathrm{i}}$. And as $\langle t, u \rangle_{\mathrm{i}}$ is a prime ideal of $E[s,t,u]$ we find that $\mathfrak{p} = \langle t, u \rangle_{\mathrm{i}}/\mathfrak{u}$ is a prime ideal of R, due to the corresopndence theorem (1.66). Now regard

$$\mathfrak{a} = \langle b, c \rangle_{\mathrm{i}}^2 = \langle b^2, bc, c^2 \rangle_{\mathrm{i}} = \langle b^2, bc, ba \rangle_{\mathrm{i}} = (bR)\langle a, b, c \rangle_{\mathrm{i}}$$

Then it is clear that $\sqrt{\mathfrak{a}} = \sqrt{\mathfrak{p}^2} = \mathfrak{p}$ and $ab = c^2 \in \mathfrak{a}$. However a (a bit cumbersome) computation yields $b \notin \mathfrak{a}$ and $a \notin \mathfrak{p} = \sqrt{\mathfrak{a}}$. This means that $\mathfrak{a}$ is not primary.

□

Proof of (2.92):

- As $\mathfrak{a} \neq R$ is a proper ideal, we have $1 \in R \setminus \mathfrak{a}$. Therefore for any $a \in \mathfrak{a}^n$ we have $a \cdot 1 \in \mathfrak{a}^n$ and thereby $a \in \mathfrak{a}^{(n)}$. This is $\mathfrak{a}^n \subseteq \mathfrak{a}^{(n)}$.

- Next we need to prove that $\mathfrak{p}^{(n)}$ truly is an ideal of R: As $0 \in \mathfrak{p}^n$ we already have $0 \in \mathfrak{p}^{(n)}$, too. Now consider any two $a, b \in \mathfrak{p}^{(n)}$, that is au and $bv \in \mathfrak{p}^n$ for some $u, v \in R \setminus \mathfrak{p}$. As $\mathfrak{p}$ is prime, we have $uv \in R \setminus \mathfrak{p}$ again. Yet also $(a+b)uv = (au)v + (bv)u \in \mathfrak{p}^n$ such that $a + b \in \mathfrak{p}^{(n)}$. Also for any $r \in R$ we get $(ra)u = r(au) \in \mathfrak{p}^n$ such that $ra \in \mathfrak{p}^{(n)}$, too. Altogether $\mathfrak{p}^{(n)}$ is an ideal of R.

- For (i) it only remains to prove $\mathfrak{p}^{(n)} \subseteq \mathfrak{p}$: So consider any $a \in \mathfrak{p}^{(n)}$, that is $au \in \mathfrak{p}^n$ for some $u \in R \setminus \mathfrak{p}$. As $au \in \mathfrak{p}^n \subseteq \mathfrak{p}$ and $\mathfrak{p}$ is prime we either have $a \in \mathfrak{p}$ or $u \in \mathfrak{p}$. But the latter is ruled out, so we are left with $a \in \mathfrak{p}$, which is $\mathfrak{p}^{(n)} \subseteq \mathfrak{p}$.

- Claim (ii) is immediate from the definition: As $\mathfrak{p}^{n+1} \subseteq \mathfrak{p}^n$ any $au \in \mathfrak{p}^{n+1}$ is already contained in $au \in \mathfrak{p}^n$. Therefore $a \in \mathfrak{p}^{(n+1)}$ implies $a \in \mathfrak{p}^{(n)}$.

- From this we can easily conclude $\sqrt{\mathfrak{p}^{(n)}} = \mathfrak{p}$: By (2.25.(vi)) and (i) we get the chain of inclusions $\mathfrak{p} = \sqrt{\mathfrak{p}^n} \subseteq \sqrt{\mathfrak{p}^{(n)}} \subseteq \sqrt{\mathfrak{p}} = \mathfrak{p}$. Hence, as the radical of $\mathfrak{p}^{(n)}$ is constrained by $\mathfrak{p}$ from both sides, it has to be equal to $\mathfrak{p}$.

- To conclude (iii) we have to prove, that $\mathfrak{p}^{(n)}$ is a primary ideal: That is we start with $ab \in \mathfrak{p}^{(n)}$ such that $b \notin \sqrt{\mathfrak{p}^{(n)}} = \mathfrak{p}$. That is there is some $u \notin \mathfrak{p}$ such that $abu \in \mathfrak{p}^n$. But as both b, $u \notin \mathfrak{p}$ and $\mathfrak{p}$ is prime, we again conclude $bu \notin \mathfrak{p}$. But $a(bu) \in \mathfrak{p}^n$ is precisely what it takes for $a \in \mathfrak{p}^{(n)}$, such that $\mathfrak{p}^{(n)}$ is primary, by property (e).

- It remains to verify (iv): As $\mathfrak{p}^n \subseteq \mathfrak{p}^{(n)}$ we already have $\mathfrak{p}^n R_{\mathfrak{p}} \subseteq \mathfrak{p}^{(n)} R_{\mathfrak{p}}$. Conversely we start with $a/u \in \mathfrak{p}^{(n)} R_{\mathfrak{p}}$ that is $av \in \mathfrak{p}^n$ for some $v \in R \setminus \mathfrak{p}$. However this already is $a/u = (av)/(uv) \in \mathfrak{p}^n R_{\mathfrak{p}}$ such that $\mathfrak{p}^{(n)} R_{\mathfrak{p}} \subseteq \mathfrak{p}^n R_{\mathfrak{p}}$, too.

□

Proof of (2.94):

(i) Suppose $\mathfrak{p} = \mathfrak{a} \cap \mathfrak{b}$ for some ideals $\mathfrak{a}$, $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{a} \neq \mathfrak{p}$ and $\mathfrak{p} \neq \mathfrak{b}$. As $\mathfrak{p} = \mathfrak{a} \cap \mathfrak{b} \subseteq \mathfrak{a}$ this means $\mathfrak{p} \subset \mathfrak{a}$, that is there is some $a \in \mathfrak{a}$ with $a \notin \mathfrak{p}$. Likewise there is some $b \in \mathfrak{b}$ with $b \notin \mathfrak{p}$. Yet $ab \in \mathfrak{a} \cap \mathfrak{b} = \mathfrak{p}$, and as $\mathfrak{p}$ is prime this yields $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$, a contradiction. Thus there are no such $\mathfrak{a}$, $\mathfrak{b}$ and this means that $\mathfrak{p}$ is irreducible.

(ii) Consider a, $b \in R$ such that $ab \in \mathfrak{p}$ but $b \notin \mathfrak{p}$. We will prove $a \in \sqrt{\mathfrak{p}}$ which is property (d) of primary ideals. Thus let $\mathfrak{b} := \mathfrak{p} + bR$. Then we regard the following ascending chain of ideals

$$\mathfrak{p} \subseteq \mathfrak{p} : a \subseteq \mathfrak{p} : a^2 \subseteq \ldots \subseteq \mathfrak{p} : a^k \subseteq \mathfrak{p} : a^{k+1} \subseteq \ldots$$

As R is noetherian this chain has to stabilize. That is there is some $s \in \mathbb{N}$ such that for all $i \in \mathbb{N}$ we get $\mathfrak{p} : a^s = \mathfrak{p} : a^{s+i}$. Now let $\mathfrak{a} := \mathfrak{p} + a^s R$. Then we will prove

$$\mathfrak{p} = \mathfrak{a} \cap \mathfrak{b}$$

The inclusion "$\subseteq$" is clear, as $\mathfrak{p} \subseteq \mathfrak{a}$ and $\mathfrak{p} \subseteq \mathfrak{b}$ by construction. Thus consider any $h \in \mathfrak{a} \cap \mathfrak{b}$. As $h \in \mathfrak{b} = \mathfrak{p} + bR$ there are some $q \in \mathfrak{p}$ and $g \in R$ such that $h = q + bg$. Therefore $ah = aq + abg \in \mathfrak{p}$ as we have $ab \in \mathfrak{p}$. And as $h \in \mathfrak{a} = \mathfrak{p} + a^s R$ as well, there are some $p \in \mathfrak{p}$ and $f \in R$ such that $h = p + a^s f$. Hence $ah = ap + a^{s+1} f$ such that $a^{s+1} f = ah - ap$. Now recall that $ah \in \mathfrak{p}$, then $a^{s+1} f = ah - ap \in \mathfrak{p}$ and this means $f \in \mathfrak{p} : a^{s+1} = \mathfrak{p} : a^s$. Therefore we have $a^s f \in \mathfrak{p}$ and this finally means $h = p + a^s f \in \mathfrak{p}$. Thus we have established $\mathfrak{p} = \mathfrak{a} \cap \mathfrak{b}$. However as $b \notin \mathfrak{p}$ we have $\mathfrak{p} \subset \mathfrak{b}$. And hence the irreducibility of $\mathfrak{p}$ yields $\mathfrak{p} = \mathfrak{a} = \mathfrak{p} + a^s R$. In particular $a^s \in \mathfrak{p}$ and that is $a \in \sqrt{\mathfrak{p}}$ which had to be shown.

(iii) Let us denote the set of all proper ideals that do *not* satisfy the claim (i.e. that are *no* finite intersection of irreducible ideals) by

$$\mathcal{A} := \{ \mathfrak{a} \trianglelefteq_{\mathrm{i}} R \mid \mathfrak{a} \neq R,\ \nexists \mathfrak{p}_1, \ldots, \mathfrak{p}_k \trianglelefteq_{\mathrm{i}} R : \text{(1) and (2)} \}$$

We have to prove $\mathcal{A} = \emptyset$, thus assume $\mathcal{A} \neq \emptyset$, as R is a noetherian ring this would mean that $\mathcal{A}$ contains a maximal element $\mathfrak{a}^* \in \mathcal{A}^*$. As $\mathfrak{a}^* \in \mathcal{A}$ we in particular have that $\mathfrak{a}^*$ is not irreducible (else $\mathfrak{a}^*$ would be its own irreducible decomposition). And as also $\mathfrak{a}^* \neq R$ this means that there are ideals $\mathfrak{a}$, $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ such that $\mathfrak{a}^* = \mathfrak{a} \cap \mathfrak{b}$ and $\mathfrak{a}^* \subset \mathfrak{a}$ and $\mathfrak{a}^* \subset \mathfrak{b}$. By maximality of $\mathfrak{a}^*$ this means $\mathfrak{a}, \mathfrak{b} \notin \mathcal{A}$ and hence there are irreducible decompositions $(\mathfrak{p}_1, \ldots, \mathfrak{p}_k)$ of $\mathfrak{a}$ and $(\mathfrak{q}_1, \ldots, \mathfrak{q}_l)$ of $\mathfrak{b}$. Hence

$$\mathfrak{a}^* \;=\; \mathfrak{a} \cap \mathfrak{b} \;=\; \left(\bigcap_{i=1}^{k} \mathfrak{p}_i\right) \cap \left(\bigcap_{j=1}^{l} \mathfrak{q}_i\right)$$

This means that $\mathfrak{a}^*$ admits $(\mathfrak{p}_1, \ldots, \mathfrak{p}_k, \mathfrak{q}_1, \ldots, \mathfrak{q}_l)$ as an irreducible decomposition and hence $\mathfrak{a}^* \notin \mathcal{A}$, a contradiction. Thus we have $\mathcal{A} = \emptyset$, that is *every* proper ideal of R admits an irreducible decomposition.

□

Proof of (2.98):
By assumption (2) we have $\mathfrak{a}_N = \mathfrak{a}$ for $N := 1 \ldots n$. And hence we may choose a subset M of minimal cardinality with this property. So step (1) of the proposition is legitimate. Now it is clear that $\approx$ is an equivalence relation on M, as it belongs to the function

$$p \;:\; M \to \operatorname{Spec}(R) \;:\; i \mapsto \sqrt{\mathfrak{a}_i}$$

Hence $A = M/\approx$ is a well defined partition of M (the equivalence classes $\alpha \in A$ are just the fibers of p). And for any $\alpha = [i] \in A$ we may define $\mathfrak{p}_\alpha := \sqrt{\mathfrak{a}_i}$. That is for any $\alpha \in A$ the set $\{\mathfrak{a}_i \mid i \in \alpha\}$ is a finite collection of primary ideals associated to $\mathfrak{p}_\alpha$. Hence by (2.90.(v)) $\mathfrak{a}_\alpha$ is a primary ideal associated to $\mathfrak{p}_\alpha$ as well. In particular $(\mathfrak{a}_\alpha)$ (where $\alpha \in A$) satisfies property (1) of primary decompositions. Further we have

$$\bigcap_{\alpha \in A} \mathfrak{a}_\alpha \;=\; \bigcap_{\alpha \in A} \bigcap_{i \in \alpha} \mathfrak{a}_i \;=\; \bigcap_{i \in M} \mathfrak{a}_i \;=\; \mathfrak{a}$$

as the α partition M and construction of M. Thus also property (2) of primary decompositions is satisfied. And property (4) is clear from the construction of A precisely by this relation. It remains to verify property (3). That is fix any $\beta = [j] \in A$ and assume $\mathfrak{a} = \bigcap_{\alpha \neq \beta} \mathfrak{a}_\alpha$. As $j \in \beta$ we in particular find

$$\mathfrak{a} \;=\; \bigcap_{i \in M} \mathfrak{a}_i \;\subseteq\; \bigcap_{j \neq i \in I} \mathfrak{a}_i \;\subseteq\; \bigcap_{\beta \neq \alpha \in A} \mathfrak{a}_\alpha \;=\; \mathfrak{a}$$

But this would mean $\mathfrak{a} = \bigcap_{i \neq j} \mathfrak{a}_i$ in contradiction to the minimality of M. Altogether we have proved properties (1) to (4), that is $(\mathfrak{a}_\alpha)$ (where $\alpha \in A$) is a minimal primary decomposition of $\mathfrak{a}$. □

Proof of (2.99):

(i) By definition $\#\mathrm{ass}(\mathfrak{a}_1, \ldots, \mathfrak{a}_k) = \#\{\mathfrak{p}_1, \ldots, \mathfrak{p}_k\} \leq k$. And if we suppose $\mathfrak{p}_i = \mathfrak{p}_j$ then by minimality of $(\mathfrak{a}_1, \ldots, \mathfrak{a}_k)$ we have $i = j$ (this is property (4)). Hence we even find $\#\{\mathfrak{p}_1, \ldots, \mathfrak{p}_k\} = k$ as claimed.

(ii) As $\mathfrak{a} = \bigcap_i \mathfrak{a}_i$ and using (2.22.(vi)) and (2.25.(v)) we can easily compute

$$\sqrt{\mathfrak{a} : u} \;=\; \sqrt{\left(\bigcap_{i=1}^{k} \mathfrak{a}_i\right) : u} \;=\; \sqrt{\bigcap_{i=1}^{k} (\mathfrak{a}_i : u)} \;=\; \bigcap_{i=1}^{k} \sqrt{\mathfrak{a}_i : u}$$

If $u \in \mathfrak{a}_i$ then we have $\mathfrak{a}_i : u = R$ according to (2.22.(iv)). And if $u \notin \mathfrak{a}_i$ then $\mathfrak{a}_i : u$ is primary again with $\sqrt{\mathfrak{a}_i : u} = \sqrt{\mathfrak{a}_i} = \mathfrak{p}_i$ by virtue of (2.90.(vi)). Thus we have obtained

$$\sqrt{\mathfrak{a} : u} \;=\; \bigcap_{i=1}^{k} \begin{cases} R \text{ if } u \in \mathfrak{a}_i \\ \mathfrak{p}_i \text{ if } u \notin \mathfrak{a}_i \end{cases}$$

Thus we may ignore any $i \in 1 \ldots k$ with $u \in \mathfrak{a}_i$, as they do not contribute to the intersection. What remains is precisely the claim

$$\sqrt{\mathfrak{a} : u} \;=\; \bigcap_{u \notin \mathfrak{a}_i} \mathfrak{p}_i$$

(iv) If $\mathfrak{p} \in \operatorname{ass}(\mathfrak{a})$ then by definition of $\operatorname{ass}(\mathfrak{a})$ there is some $u \in R$ such that $\mathfrak{p} = \sqrt{\mathfrak{a} : u}$. Thus by (ii) we have the identity

$$\mathfrak{p} \;=\; \bigcap_{u \notin \mathfrak{a}_i} \mathfrak{p}_i$$

And hence by (2.14.(ii)) there is some $i \in 1 \ldots k$ satisfying ($u \notin \mathfrak{a}_i$ and) $\mathfrak{p}_i \subseteq \mathfrak{p}$. And as $\mathfrak{p} \subseteq \mathfrak{p}_i$ is clear this is $\mathfrak{p} = \mathfrak{p}_i \in \operatorname{ass}(\mathfrak{a}_1, \ldots, \mathfrak{a}_k)$. Conversely choose any $j \in 1 \ldots k$. As $(\mathfrak{a}_1, \ldots, \mathfrak{a}_k)$ is minimal we have $\mathfrak{a} \subset \bigcap_{i \neq j} \mathfrak{a}_i$ and hence there is some $u_i \in \mathfrak{a}_i$ for any $i \neq j$ but $u_j \notin \mathfrak{u}_j$. Thus for this u_j by (ii) we get

$$\bigcap_{u_j \notin \mathfrak{a}_i} \mathfrak{p}_i \;=\; \mathfrak{p}_j \;=\; \sqrt{\mathfrak{a} : u_j} \;\in\; \operatorname{ass}(\mathfrak{a})$$

(iii) Without loss of generality we consider $\mathfrak{p}_1 \in \operatorname{ass}(\mathfrak{a}_1, \ldots, \mathfrak{a}_k)_*$. That is for any $i \in 2 \ldots k$ we have $\mathfrak{p}_i \not\subseteq \mathfrak{p}_1$. And this again means that there is some $a \in \mathfrak{p}_i$ with $a \notin \mathfrak{p}_1$. Now let $U := R \setminus \mathfrak{p}_1$, in particular $a \in U$. Then because of $a \in \mathfrak{p}_i = \sqrt{\mathfrak{a}_i}$ there is some $n \in \mathbb{N}$ such that $a^n \in \mathfrak{a}_i$. And as $a^n \in U$, too, we get $1/1 = (a^n)/(a^n) \in U^{-1}\mathfrak{a}_i$. Hence we get $U^{-1}\mathfrak{a}_i = U^{-1}R$ and this again means

$$R \;=\; \left(U^{-1}\mathfrak{a}_i\right) \cap R \;=\; \mathfrak{a}_i : U$$

for any $i \in 2 \ldots k$. This now can be used to prove $\mathfrak{a} : U = \mathfrak{a}_1$ by virtue of the following computation (see (2.125) - for convenience we even gave an elementary proof of $(\mathfrak{a} \cap \mathfrak{b}) : U = (\mathfrak{a} : U) \cap (\mathfrak{b} : U)$ there)

$$\mathfrak{a} : U \;=\; \left(\bigcap_{i=1}^{k} \mathfrak{a}_i\right) : U \;=\; \bigcap_{i=1}^{k} (\mathfrak{a}_i : U) \;=\; \mathfrak{a}_1 : U \;=\; \mathfrak{a}_1$$

Hereby $\mathfrak{a}_1 : U = \mathfrak{a}_1$ holds true because $\mathfrak{a}_1$ is primary and $U = R \setminus \mathfrak{p}_1$. To be precise consider $a \in \mathfrak{a}_i : U$, that is there is some $u \in U$ such that $au \in \mathfrak{a}_i$. But by definition of U we have $u \notin \mathfrak{p}_1 = \sqrt{\mathfrak{a}_1}$, and as $\mathfrak{a}_1$ is primary this yields $a \in \mathfrak{a}_1$. Thus we have $\mathfrak{a}_1 : U \subseteq \mathfrak{a}_1$ and the converse inclusion is trivial.

(v) If $\mathfrak{p} \in \operatorname{ass}(\mathfrak{a})_*$ then by virtue of (iv) we have $\mathfrak{p} = \mathfrak{p}_i$ for some $i \in 1 \ldots k$. And as $\mathfrak{p}_i$ is minimal (iii) implies $\mathfrak{a} : (R \setminus \mathfrak{p}) = \mathfrak{a}_i \in \operatorname{iso}(\mathfrak{a}_1, \ldots, \mathfrak{a}_k)$. Conversely consider any $\mathfrak{a}_i \in \operatorname{iso}(\mathfrak{a}_1, \ldots, \mathfrak{a}_k)$. Then by

definition $\mathfrak{p}_i \in \operatorname{ass}(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)_*$ and by (iii) this means $\mathfrak{a}_i = \mathfrak{a} : (R \setminus \mathfrak{p})$. And by (iv) we also have $\mathfrak{p}_i \in \operatorname{ass}(\mathfrak{a})_*$ and thereby $\mathfrak{a}_i \in \operatorname{iso}(\mathfrak{a})$.

□

Proof of (2.101):

(1) By (2.94.(iii)) there are some irreducible ideals $\mathfrak{p}_1,\ldots,\mathfrak{p}_k \trianglelefteq_{\mathrm{i}} R$ such that $\mathfrak{a} = \mathfrak{p}_1 \cap \cdots \cap \mathfrak{p}_k$. And by (2.94.(ii)) these irreducible ideals already are primary. Thus $(\mathfrak{p}_1,\ldots,\mathfrak{p}_k)$ is a primary decomposition of $\mathfrak{a}$. And by (2.98) we find that $\mathfrak{a}$ then already has a minimal primary decomposition.

(2) Now assume that $(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)$ and $(\mathfrak{b}_1,\ldots,\mathfrak{b}_l)$ are minimal primary decompositions of $\mathfrak{a}$. Then by (2.99.(iii)) we get the identity

$$\operatorname{ass}(\mathfrak{a}_1,\ldots,\mathfrak{a}_k) \;=\; \operatorname{ass}(\mathfrak{a}) \;=\; \operatorname{ass}(\mathfrak{b}_1,\ldots,\mathfrak{b}_l)$$

(Note that by definition $\operatorname{ass}(\mathfrak{a})$ and $\operatorname{iso}(\mathfrak{a})$ only depend on $\mathfrak{a}$, not on the decomposition). And by (2.99.(i)) this in particular implies $k = l$. The third identity we finally get from (2.99.(iv))

$$\operatorname{iso}(\mathfrak{a}_1,\ldots,\mathfrak{a}_k) \;=\; \operatorname{iso}(\mathfrak{a}) \;=\; \operatorname{iso}(\mathfrak{b}_1,\ldots,\mathfrak{b}_l)$$

(3) Let us denote the minimal prime ideals over $\mathfrak{a}$ by $\mathfrak{a}_i$, that is we let $\{\mathfrak{a}_1,\ldots,\mathfrak{a}_k\} := \{\mathfrak{p} \in \operatorname{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p}\}_*$ (note that there are only finitely many $\mathfrak{a}_i$, due to (2.45.(iii))). Then by (2.25.(i)) we have

$$\mathfrak{a} \;=\; \sqrt{\mathfrak{a}} \;=\; \bigcap \{\,\mathfrak{p} \in \operatorname{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p}\,\}_* \;=\; \bigcap_{i=1}^{k} \mathfrak{a}_i$$

And as the $\mathfrak{a}_i$ are prime they in particular are primary according to (2.94.(i)). That is $(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)$ is a primary decomposition of $\mathfrak{a}$. And as $\sqrt{\mathfrak{a}_i} = \mathfrak{a}_i \neq \mathfrak{a}_j = \sqrt{\mathfrak{a}_j}$ (for $i \neq j$) it even satisfies property (4) of minimal primary decompositions. Now assume that for some index $j \in 1\ldots k$ we had the equality

$$\bigcap_{i \neq j} \mathfrak{a}_i \;=\; \mathfrak{a} \;\subseteq\; \mathfrak{a}_j$$

Then by (2.14.(ii)) there would be some $i \neq j$ such that $\mathfrak{a} \subseteq \mathfrak{a}_i \subseteq \mathfrak{a}_j$. And by minimality of $\mathfrak{a}_j$ this would mean $\mathfrak{a}_i = \mathfrak{a}_j$, a contradiction. Thus $(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)$ also satisfies property (3), that is it *is* a minimal primary decomposition of $\mathfrak{a}$. In fact this even is $\operatorname{ass}(\mathfrak{a}_1,\ldots,\mathfrak{a}_k) = \operatorname{iso}(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)$, that is every associated ideal is an isolated component. Now assume that $(\mathfrak{b}_1,\ldots,\mathfrak{b}_l)$ is any minimal primary decomposition of $\mathfrak{a}$, then by (2) we have $l = k$ and

$$\begin{aligned} \{\,\mathfrak{a}_1,\ldots,\mathfrak{a}_k\,\} &= \operatorname{ass}(\mathfrak{a}_1,\ldots,\mathfrak{a}_k) \\ &= \operatorname{iso}(\mathfrak{a}_1,\ldots,\mathfrak{a}_k) \\ &= \operatorname{iso}(\mathfrak{b}_1,\ldots,\mathfrak{b}_k) \end{aligned}$$

That is for any $i \in 1\ldots k$ we have $\mathfrak{a}_i \in \operatorname{iso}(\mathfrak{b}_1,\ldots,\mathfrak{b}_k) = \{\,\mathfrak{a}_1,\ldots,\mathfrak{a}_k\,\}$ and this again means that for any $i \in 1\ldots k$ there is some $\sigma(i) \in 1\ldots k$ such that $\mathfrak{b}_i = \mathfrak{a}_{\sigma(i)}$. Clearly σ is injective, because if we assume $\sigma(i) = \sigma(j)$ then $\mathfrak{b}_i = \mathfrak{a}_{\sigma(i)} = \mathfrak{a}_{\sigma(j)} = \mathfrak{b}_j$ in contradiction to the minimality

of $(\mathfrak{b}_1,\ldots,\mathfrak{b}_k)$. But as k is finite this already means that σ is bijective, that is $\sigma \in S_k$. Altogether $(\mathfrak{b}_1,\ldots,\mathfrak{b}_k)$ is just a rearranged version of $(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)$.

□

Proof of (2.102):

(i) Let $(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)$ be a minimal primary decomposition of $\mathfrak{a}$ (which exists, due to (2.101)) and $\mathfrak{p}_i := \sqrt{\mathfrak{a}_i}$. Then we have seen in (2.99.(iv)) that $\operatorname{ass}(\mathfrak{a}) = \{\mathfrak{p}_1,\ldots,\mathfrak{p}_k\}$. Thus from $\bigcap_i \mathfrak{a}_i = \mathfrak{a} \subseteq \mathfrak{q}$ we get $\mathfrak{a}_i \subseteq \mathfrak{q}$ for some $i \in 1\ldots k$, according to (2.14.(ii)). Therefore $\mathfrak{p}_i = \sqrt{\mathfrak{a}_i} \subseteq \sqrt{\mathfrak{q}} = \mathfrak{q}$ and $\mathfrak{p}_i \in \operatorname{ass}(\mathfrak{a})$. Now let $\mathfrak{p}_j \subseteq \mathfrak{q}$ for some $\mathfrak{p}_j \in \operatorname{ass}(\mathfrak{a})$. Then we may choose some minimal $\mathfrak{p}_i \in \operatorname{ass}(\mathfrak{a})_*$ with $\mathfrak{p}_i \subseteq \mathfrak{p}_j$ (as $\operatorname{ass}(\mathfrak{a})$ is finite). And hence we get $\mathfrak{a}_i \subseteq \mathfrak{p}_i \subseteq \mathfrak{p}_j \subseteq \mathfrak{q}$, that is $\mathfrak{a}_i \subseteq \mathfrak{q}$. Finally consider $\mathfrak{a}_i \subseteq \mathfrak{q}$ then $\mathfrak{a} \subseteq \mathfrak{a}_i \subseteq \mathfrak{q}$ is clear.

(ii) We stick to the notation used for (i) that is $(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)$ is a minimal primary decomposition and $\mathfrak{p}_i := \sqrt{\mathfrak{a}_i}$. "$\subseteq$" if $\mathfrak{a} \subseteq \mathfrak{q}$ then by (i) there exists some $\mathfrak{a}_i \in \operatorname{iso}(\mathfrak{a})$ such that $\mathfrak{a}_i \subseteq \mathfrak{q}$. Then $\mathfrak{a} \subseteq \mathfrak{a}_i \subseteq \mathfrak{p}_i = \sqrt{\mathfrak{a}_i} \subseteq \sqrt{\mathfrak{q}} = \mathfrak{q}$. By minimality of $\mathfrak{q}$ this yields $\mathfrak{q} = \mathfrak{p}_i \in \operatorname{ass}(\mathfrak{a})_*$. "$\supseteq$" conversely, if $\mathfrak{p}_i \in \operatorname{ass}_*$ then $\mathfrak{a} \subseteq \mathfrak{a}_i \subseteq \mathfrak{p}_i$. Thus if we consider any prime ideal $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ such that $\mathfrak{a} \subseteq \mathfrak{p} \subseteq \mathfrak{p}_i$, then by (i) there is some $\mathfrak{p}_j \in \operatorname{ass}(\mathfrak{a})$ such that $\mathfrak{p}_j \subseteq \mathfrak{p} \subseteq \mathfrak{p}_i$. By minimality of $\mathfrak{p}_i$ in $\operatorname{ass}(\mathfrak{a})$ this means $\mathfrak{p}_j = \mathfrak{p}_i$ and hence $\mathfrak{p} = \mathfrak{p}_i$. Hence $\mathfrak{p}_i$ is a minimal prime ideal containing $\mathfrak{a}$.

(iii) This follows immediately from (ii) and (2.25.(i)): by the propositions cited, we have $\sqrt{\mathfrak{a}} = \bigcap\{\mathfrak{q} \in \operatorname{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{q}\} = \bigcap \operatorname{ass}(\mathfrak{a})_*$. And it is clear that $\bigcap \operatorname{ass}(\mathfrak{a}) \subseteq \bigcap \operatorname{ass}(\mathfrak{a})_*$, as $\operatorname{ass}(\mathfrak{a})_* \subseteq \operatorname{ass}(\mathfrak{a})$. But on the other hand, if $\mathfrak{i} \in \operatorname{ass}(\mathfrak{a})$ there some $\mathfrak{i}_* \in \operatorname{ass}(\mathfrak{a})_*$ such that $\mathfrak{i}_* \subseteq \mathfrak{i}$ (as $\operatorname{ass}(\mathfrak{a})$ is finite). Thus we also have $\bigcap \operatorname{ass}(\mathfrak{a})_* \subseteq \bigcap \operatorname{ass}(\mathfrak{a})$.

□

Proof of (2.105):

We will first prove the ζ truly is a homomorphism of rings. By definition we have $\zeta(0) = 0_R$ and $\zeta(1) = 1_R$. If now $k \in \mathbb{N}$ then $\zeta(-k) = k(-1_R) = -(k1_R) = -\zeta(k)$ by general distributivity. Hence we have $\zeta(-k) = -\zeta(k)$ *for any* $k \in \mathbb{Z}$ (because if $k < 0$ then $-k \in \mathbb{N}$ and hence $-\zeta(k) = -\zeta(--k) = --\zeta(-k) = \zeta(-k)$). This will be used to prove the additivity of ζ. First of all it is clear that for i, $j \in \mathbb{N}$ we get

$$\zeta(i+j) \;=\; (i+j)1_R \;=\; (i1_R) + (j1_R) \;=\; \zeta(i) + \zeta(j)$$

And likewise $\zeta((-i)+(-j)) = \zeta(-(i+j)) = -\zeta(i+j) = -(\zeta(i)+\zeta(j)) = -\zeta(i) + -\zeta(j) = \zeta(-i) + \zeta(-j)$. Now assume $i \geq j$ then by general associativity it is clear that $\zeta(i+(-j)) = \zeta(i-j) = (i-j)1_R = (i1_R) - (j1_R) = \zeta(i) - \zeta(j) = \zeta(i) + \zeta(-j)$. And if $i \leq j$ then $\zeta(i+(-j)) = \zeta(-(j-i)) = -\zeta(j-i) = -\zeta(j) + \zeta(-i) = \zeta(-j) + -\zeta(-i) = \zeta(i) + \zeta(-j)$. Thus in any case we have $\zeta(i+(-j)) = \zeta(i)+\zeta(-j)$ and likewise we see $\zeta((-i)+j) = \zeta(-i)+\zeta(j)$. Thus we have finally arrived at $\zeta(i+j) = \zeta(i)+\zeta(j)$ for any i, $j \in \mathbb{Z}$. For the multiplicativity things are considerably simpler: let i, $j \in \mathbb{N}$ again, then by the general rule of distributivity we get $\zeta(ij) = (ij)1_R = (i1_R)(j1_R) = \zeta(i)\zeta(j)$. And as also $\zeta(-k) = -\zeta(k)$ this clearly yields $\zeta(ij) = \zeta(i)\zeta(j)$ for any i, $j \in \mathbb{Z}$. Thus ζ is a homomorphism of rings. And if $\varphi : \mathbb{Z} \to R$ is any homomorphism, then $\varphi(1) = 1_R$. By induction on $k \in \mathbb{N}$ we see $\varphi(k) = \varphi(1+\cdots+1) = \varphi(1)+\cdots+\varphi(1) = 1_R+\cdots+1_R = k1_R = \zeta(k)$. And of course $\varphi(-k) = -\varphi(k) = -\zeta(k) = \zeta(-k)$ such that $\varphi = \zeta$. This also is the uniqueness of ζ.

Thus $\mathrm{im}(\zeta)$ is a sub-ring of R by virtue of (1.76.(v)). Let us denote the intersection of all sub-rings of R by P - note that this is a sub-ring again, due to (1.52). From the construction of P it is clear, that $P \subseteq \mathrm{im}(\zeta) \leq_\mathrm{r} R$. But as $1_R \in P$ we have and hence $\zeta(k) = k1_R \in P$ f0r any $k \in \mathbb{N}$. Likewise $-1_R \in P$ and hence $\zeta(-k) = k(-1_R) \in P$. This is the converse inclusion $\mathrm{im}(\zeta) \subseteq P$ and hence $\mathrm{im}(\zeta) = P$.
Now $\mathrm{kn}(\zeta) \trianglelefteq_\mathrm{i} \mathbb{Z}$ is an ideal in $\mathbb{Z}$ due to (1.76.(v)) again. But as $(\mathbb{Z}, \alpha)$ is an Euclidean domain $\mathbb{Z}$ is a PID due to (2.79.(iii)). Hence there is some $n \in \mathbb{Z}$ such that $\mathrm{kn}(\zeta) = n\mathbb{Z}$. Thereby n is determined up to associatedness. And as $\mathbb{Z}^* = \{1, -1\}$ this is n is uniquely determined up to sign $\pm n$. Thus by fixing $n \geq 0$ it is uniquely determined. Now

$$\begin{aligned}\mathrm{kn}(\zeta) &= \{\, k \in \mathbb{Z} \mid \zeta(k) = 0_R \,\} \\ &= \{\, \pm k \mid k \in \mathbb{N},\ \zeta(k) = 0_R \,\} \\ &= \{\, \pm k \mid k \in \mathbb{N},\ k1_R = 0_R \,\}\end{aligned}$$

Thus if $n = 0$ then $\mathrm{kn}(\zeta) = 0$ and hence $k1_R = 0_R$ implies $k \in \mathrm{kn}(\zeta) = 0$ which is $k = 0$. And if $n \neq 0$ then $\mathrm{kn}(\zeta) \neq 0$. And hence we have seen in (2.79.(iii)) that $\alpha(n) = |n| = n$ is minimal in $\mathrm{kn}(\zeta)$. And due to the explict realisation of the kernel above this is $n = \min\{\, 1 \leq k \in \mathbb{N} \mid k1_R = 0 \,\}$. □

Proof of (2.107):

(i) As R is an integral domain, so are its sub-rings $P \leq_\mathrm{r} R$. In particular $\mathrm{im}(\zeta) \leq_\mathrm{r} R$ is an integral domain. But by definition and (1.83.(ii)) we've got the isomorphy (where $n := \mathrm{CHAR}(R)$)

$$\mathbb{Z}\big/_{n\mathbb{Z}} = \mathbb{Z}\big/_{\mathrm{kn}(\zeta)} \cong_\mathrm{r} \mathrm{im}(\zeta) = \mathrm{PRR}(R) \leq_\mathrm{r} R$$

Hence $\mathbb{Z}/n\mathbb{Z}$ is an integral domain, too and by (2.12) this implies that $n\mathbb{Z} = \mathbb{Z}$ or $n\mathbb{Z}$ is a prime ideal in $\mathbb{Z}$. If we had $n\mathbb{Z} = \mathbb{Z}$, then $n = 1$, which would mean $1_R = 0_R$ in contradiction to $R \neq 0$. This only leaves, that $n\mathbb{Z}$ is a prime ideal. But this again means that $n = 0$ or that n is prime because of (2.58.(ii)).

(ii) Suppose $n := \mathrm{CHAR}(R) = 0$ and $k_R = 0_R$, then $k \in \mathrm{kn}(\zeta) = n\mathbb{Z} = 0$ which is $k = 0$. Conversely suppose $n \in n\mathbb{Z} = \mathrm{kn}(\zeta)$, that is $n_R = \zeta(n) = 0_R$ and by assumption this implies $n = 0$. We now prove the second equivalence. That is we assume $n = 0$ and want to show $\zeta : \mathbb{Z} \cong_\mathrm{r} \mathrm{PRR}(R)$. But as in (i) we find the following isomorphies

$$\mathbb{Z} \cong_\mathrm{r} \mathbb{Z}\big/_{0\mathbb{Z}} = \mathbb{Z}\big/_{\mathrm{kn}(\zeta)} \cong_\mathrm{r} \mathrm{im}(\zeta) = \mathrm{PRR}(R)$$

where $k \mapsto k + 0\mathbb{Z} = k + \mathrm{kn}(\zeta) \mapsto \zeta(k)$ - which precisely is ζ again. Conversely suppose $\Phi : \mathbb{Z} \cong_\mathrm{r} \mathrm{PRR}(R)$ for some isomorphism Φ. If we had $n \neq 0$, then $\mathbb{Z}_n = \mathbb{Z}/n\mathbb{Z}$ would be finite. But as we have the isomorphy $\mathbb{Z} \cong_\mathrm{r} \mathrm{PRR}(R) \cong_\mathrm{r} \mathbb{Z}_n$ once more this cannot be (as we thereby find the contradiction $\infty = \#\mathbb{Z} = \#\mathbb{Z}_n = n < \infty$).

(iii) If $n := \mathrm{CHAR}(R) \neq 0$, then we have already proved the minimality of n, that is $n = \min\{\, 1 \leq k \in \mathbb{N} \mid k_R = 0_R \,\}$ in (2.105). Conversely suppoese n is this minimum and denote $c := \mathrm{CHAR}(R)$. As $c_R = 0_R$ and n is minimal with this property we have $n \leq c$. On the other hand we have $\zeta(n) = n_R = 0_R$ and hence $n \in \mathrm{kn}(\zeta) = c\mathbb{Z}$. That is $c \mid n$ and hence $c \leq n$, altogether $n = c = \mathrm{CHAR}(R)$. And $n \neq 0$ is trivial (as n is contained in a subset of $\{k \mid 1 \leq k \in \mathbb{N}\}$). The second equivalence results from the

following isomorphy again (refer to (1.83.(ii))

$$\mathbb{Z}_n \;=\; \mathbb{Z}\big/_{n\mathbb{Z}} \;=\; \mathbb{Z}\big/_{\mathsf{kn}(\zeta)} \;\cong_{\mathsf{r}}\; \mathsf{im}(\zeta) \;=\; \mathsf{PRR}(R)$$

where $k + n\mathbb{Z} = k + \mathsf{kn}(\zeta) \mapsto \zeta(k)$. Thus if $\mathsf{CHAR}R = n \neq 0$ we are done already. Conversely suppose there was some isomorphism Φ such that $\Phi : \mathbb{Z}_n \;\cong_{\mathsf{r}}\; \mathsf{PRR}(\mathbb{Z})$. Then we had (where $c := \mathsf{CHAR}(R)$ again)

$$\mathbb{Z}_c \;=\; \mathbb{Z}\big/_{\mathsf{kn}(\zeta)} \;\cong_{\mathsf{r}}\; \mathsf{im}(\zeta) \;=\; \mathsf{PRR}(R) \;\cong_{\mathsf{r}}\; \mathbb{Z}_n$$

In particular we find $c = \#\mathbb{Z}_c = \#\mathbb{Z}_n = n$ (as $n \neq 0$ and hence $c \neq 0$). That is we have found $n = c = \mathsf{CHAR}(R)$ and $n \neq 0$ has been assumed.

(iv) If $n := \mathsf{CHAR}(R) = 0$, then by (ii) we have $\zeta : \mathbb{Z} \;\cong_{\mathsf{r}}\; \mathsf{PRR}(R)$. And as $\mathsf{PRF}(R)$ is the quotient field of $\mathsf{PRR}(R)$ this implies $\mathbb{Q} \;\cong_{\mathsf{r}}\; \mathsf{PRF}(R)$ under the isomorphy $a/b \mapsto \zeta(a)\zeta(b)^{-1}$. Likewise if $n := \mathsf{CHAR}(R) \neq 0$ then by (iii) we have $\mathbb{Z}_n \;\cong_{\mathsf{r}}\; \mathsf{PRR}(R)$. As R is a field it is a non-zero integral domain. Thus by (i) n is prime. Hence $n\mathbb{Z}$ is a non-zero prime ideal and hence maximal (due to (2.79.(i))), such that $\mathbb{Z}_n$ is a field. As $\mathsf{PRF}(R)$ is the quotient field of (the field) $\mathsf{PRR}(R)$ this implies $\mathbb{Z}_n \;\cong_{\mathsf{r}}\; \mathsf{PRR}(R) = \mathsf{PRF}(R)$. Conversely if $\mathbb{Q} \;\cong_{\mathsf{r}}\; \mathsf{PRF}(R)$, then $\mathsf{CHAR}(R) = 0$ as else $\mathbb{Z}_n \;\cong_{\mathsf{r}}\; \mathsf{PRF}(R) \;\cong_{\mathsf{r}}\; \mathbb{Q}$ (where $n = \mathsf{CHAR}(R) \neq 0$) by what we have just proved. And if $\Phi : \mathbb{Z}_n \;\cong_{\mathsf{r}}\; \mathsf{PRF}(R)$ for some isomorphism Φ, then we have $n_R = n1_R = n\Phi(1 + n\mathbb{Z}) = \Phi(n + n\mathbb{Z}) = \Phi(0 + n\mathbb{Z}) = 0_R$. Thus if $c := \mathsf{CHAR}(R)$, then $n \in \mathsf{kn}(\zeta) = c\mathbb{Z}$ and hence $c \mid n$. On the other hand we have $0_R = c_R = c1_R = c\Phi(1 + n\mathbb{Z}) = \Phi(c + n\mathbb{Z})$. From the injectivity of Φ we get $c + n\mathbb{Z} = 0 + n\mathbb{Z}$ and hence $n \mid c$. As both n and c are positive this only leaves $n = c$.

(v) First suppose we had $c := \mathsf{CHAR}(R) = 0$, then $\zeta : \mathbb{Z} \hookrightarrow R$ would be injective (as $\mathsf{kn}(\zeta) = c\mathbb{Z} = 0$), which contradicts R being finite. Thus we have $c \neq 0$, now let $P := \mathsf{PRR}(R)$, then by (iii) we have $P \;\cong_{\mathsf{r}}\; \mathbb{Z}_c$ and hence $\#P = \#\mathbb{Z}_c = c$. But - being a sub-ring - $P \;\leq_{\mathsf{g}}\; R$ is a subgroup (under the addition $+$ on R). Thus by the theorem of Lagrange (1.7) we have $c = \#P \mid \#R$.

□

Proof of (2.108):

- First of all note that $\mathbb{Z}$ is an euclidean domain (2.71) and hence a PID, which in turn implies that $\mathbb{Z}$ is an UFD (2.79) (iii) and (ii). That is we may use prime decompositions in $\mathbb{Z}$.

- Let $m \in 2 \ldots n$ be the minimal number such that $m \mid n$. That is $qm = n$ for some $1 \leq q < n$. If n is prime, then $n = m$ and conversely if $m < n$ then $n \nmid m$ and $n \nmid q$ such that n is not a prime number. For any $k \in \mathbb{Z}$ the map

$$\mu_k \;:\; \mathbb{Z}_n \;\to\; \mathbb{Z}_n \;:\; a + n\mathbb{Z} \mapsto ka + n\mathbb{Z}$$

is additive (a homomorphism of the additive group $(\mathbb{Z}_n, +)$, as $k(a + b) = ka + kb$ and this equation transfers to $\mathbb{Z}_n$. Let now k be relatively prime to n - that is $1 \in \gcd(k, n)$. Then μ_k even is injective: Suppose $ka + n\mathbb{Z} = kb + n\mathbb{Z}$, then $k(b - a) \in n\mathbb{Z}$ and this means $n \mid k(b - a)$. By (2.64.(iv)) this implies $n \mid (b - a)$ which is $b - a \in n\mathbb{Z}$ and thereby $a + n\mathbb{Z} = b + n\mathbb{Z}$. We are now ready to

prove

$$\mathbb{Z}_n^* \;=\; \{\, k+n\mathbb{Z} \mid 1 \in \gcd(k,n) \,\}$$

If $1 \in \gcd(k,n)$ then $\mu_k : \mathbb{Z}_n \hookrightarrow \mathbb{Z}_n$ is injective. As $\mathbb{Z}_n$ is a finite set, this means μ_k is bijective and hence there is a $j+n\mathbb{Z}$ such that $\mu_k(j+n\mathbb{Z}) = 1+n\mathbb{Z}$. By construction this is $(k+n\mathbb{Z})(j+n\mathbb{Z}) = kj+n\mathbb{Z} = 1+n\mathbb{Z}$ and thereby $k+n\mathbb{Z} = (j+n\mathbb{Z})^{-1}$ is a unit. Conversely suppose $d \mid k$ and $d \mid n$ for some $d \geq 2$. Say $rd = k$ and $sd = n$. Then $s < n$ as $d \geq 2$ and thereby $s+n\,\{\,Z\,\} \neq 0+n\mathbb{Z}$. Yet $sk = s(rd) = r(sd) = rn$ such that $(s+n\mathbb{Z})(k+n\mathbb{Z}) = rn+n\mathbb{Z} = 0+n\mathbb{Z}$. If $k+n\mathbb{Z}$ was a unit we could multiply with its inverse and find $s+n\mathbb{Z} = 0+n\mathbb{Z}$ a contradiction. Thus $k+n\mathbb{Z}$ is a unit if and only if $1 \in \gcd(k,n)$.

- Now the equivalences are easy: If (a) n is a prime number, then any $k \in \mathbb{Z}$ with $1 \leq k < n$ is relatively prime to n. And hence $k+n\mathbb{Z}$ is a unit of $\mathbb{Z}_n$. That is $\mathbb{Z}_n^* = \mathbb{Z}_n \setminus \{\, 0+n\mathbb{Z} \,\}$ which means $\mathbb{Z}_n$ is a field (b). Any field is an integral domain, so we also get (c). Now if (c) $\mathbb{Z}_n$ is an integral domain, suppose n was not prime, then there were some a, $b \in \mathbb{Z}$ such that $n \mid ab$ but n does neither divide a nor b. Say $qn = ab$, then we have $(a+n\mathbb{Z})(b+n\mathbb{Z}) = qn+n\mathbb{Z} = 0+n\mathbb{Z}$. As n does not divide a we have $a+n\mathbb{Z} \neq 0+n\mathbb{Z}$ and likewise $b+n\mathbb{Z} \neq 0+n\mathbb{Z}$. But this contradicts $\mathbb{Z}_n$ being an integral domain, so we conclude, that n is prime.

□

Proof of (2.109):

(i) Consider a unit $a \in R^*$ of R and suppose $ab = 0$, then $b = a^{-1}0 = 0$ and hence a is no zero-divisor of R. Conversely suppose that $a \notin \mathrm{zD}(R)$ is a non-zero-divisor of R. Then the mapping

$$R \hookrightarrow R \;:\; b \mapsto ab$$

is injective (as $ab = ac$ implies $a(b-c) = 0$ and as $a \notin \mathrm{zD}(R)$ this yields $b-c = 0$ such that $b = c$). But as R is finite any injective map on R also is surjective (and vice versa). Hence there is some $b \in R$ such that $ab = 1$. But this means that $a \in R^*$ is a unit of R.

(ii) For any finite group G we may define the *exponent* of G to be the least common multiple of the orders of its elements

$$\exp(G) \;:=\; \mathrm{lcm}\{\, \mathrm{ord}(x) \mid x \in G \,\}$$

By the Theorem of Lagrange we have $\mathrm{ord}(x) \mid \#G$ for any $x \in G$ such that the least common multiple $\exp(G)$ of the orders is a divisor of $\#G$, as well. By (??) there is some element $g \in G$ such that $\mathrm{ord}(g) = \exp(G)$. Thus if we have $\#G = \exp(G)$ then G is cyclic as it then is generated by the element $g \in G$ with $\mathrm{ord}(g) = \exp(G) = \#G$.

Let now G be a finite subgroup of F^* and let us denote $n := \#G$ and $m := \exp(G)$. Then we need to show $m = n$. As $m \mid n$ we already have $m \leq n$ so it only remains to show $n \leq m$. Now choose any $x \in G \subseteq F^*$, then by construction $x^m = 1$ and hence x is a root of the polynomial $t^m - 1$. Thus we have found n different roots of $t^m - 1$ (namely the elements of G). But the number of roots of $t^m - 1$ is bounded by

$$n \;\leq\; \deg(t^m - 1) \;=\; m$$

(iii) As F has n elements, the multiplicative group $F^* = F \setminus \{0\}$ contains $n-1$ elements. Hence by the theorem of Lagrange (1.9) we get $a^{n-1} = 1$ for any $a \in F^*$. Multiplying this by a we get $a^n = a$. And $0^n = 0$ is clear, as well, such that we get $a^n = a$ for any $a \in F$.

Let $z(t) := t^n - t \in F[t]$, then we have just seen $z(a) = 0$ for any $a \in F$. By (7.54.(iii)) this implies $t - a \mid z$. Now by (2.7.(i)) any $(t-a)F[t]$ is a maximal and hence prime ideal. Therefore the $t - a$ are distinct prime elements of $F[t]$ and therefore

$$p(t) \;:=\; \prod_{a \in F} (t-a) \;\mid\; z$$

by (2.59.(vi)). But as F contains n elements, $p(t) \in F[t]$ is of degree n, just like $z(t)$. Suppose $z(t) = p(t) \cdot q(t)$, then $\deg(q) = \deg(z) - \deg(q) = 0$ such that $q(t) = u$ for some $q \in F$. But both p and z are monic, so q must have leading coefficient $u = 1$, as well. And this is $q(t) = 1$ such that we find the identity $z(t) = p(t)$ of these two polynomials.

(iv) If $f = pa$ then we easily have $(f + p^n S)(p^{n-1} + p^n S) = p^n a + p^n S = 0 + p^n S$. And as S is an integral domain we have $p^n \not\mid p^{n-1}$ or in other words $p^{n-1} + p^n S \neq 0 + p^n S$. And hence $f + p^n S$ is a zero-divisor of $S/p^n S$. Conversely suppose $(f + p^n S)(g + p^n S) = 0 + p^n S$ for some $g + p^n S \neq 0 + p^n S$. This means $p^n \not\mid g$ and hence we obtain a well-defined $l \in 1 \ldots n-1$ by letting

$$l \;:=\; g[p] \;:=\; \max\Big\{ k \in \mathbb{N} \mid p^k \mid g \Big\}$$

If we now write $g = p^l b$ then by assumption we have $p^n \mid fg = fp^l b$ and hence $p \mid p^{n-l} \mid fb$. As p is prime we get $p \mid f$ or $p \mid b$. But as l has been chosen maximally $p \mid b$ is absurd, which only leaves $p \mid f$.

(v) As $R \neq 0$ (because of $p^n S \subseteq pS \neq S$) we have already seen the inclusions $\mathrm{nil}(R) \subseteq \mathrm{zd}(R) \subseteq R \setminus R^*$ in (1.47.(ii)). And by (ii) we already know $\mathrm{zd}(R) = (p + p^n S)R$. And if $pa + p^n S \in \mathrm{zd}(R)$ then

$$(pa + p^n S)^n \;=\; p^n a^n + p^n S \;=\; 0 + p^n S$$

which also proves $\mathrm{zd}(R) \subseteq \mathrm{nil}(R)$. Thus it only remains to prove the inclusion $R \setminus R^* \subseteq (p + p^n S)R$. Thus consider $x = f + p^n S \notin R^*$, in particular we have $f \notin S^*$ (as else $x^{-1} = f^{-1} + p^n S$). Thus f has a true (i.e. $r \geq 1$) prime factorization

$$f \;=\; \alpha q \quad \text{where} \quad q \;:=\; \prod_{i=1}^{r} q_i$$

with $\alpha \in S^*$ and $q_i \in S$ prime. Now suppose that p is not associated to any of the q_i (formally that is $\neg(p \approx q_i)$ for any $i \in 1 \ldots r$) then we had $\gcd(p^n, q) = 1$. The lemma of Bezout (2.83.(iii)) then implies

$$p^n S + qS \;=\; \gcd(p^n, q)S \;=\; S$$

Therefore there are a and $b \in S$ such that $ap^n + bq = 1$ or in other words $bq = 1 - ap^n$. Now let $g := ap^n + \alpha^{-1} b$, then it is clear that

$$fg \;=\; \alpha q(ap^n + \alpha^{-1} b) \;=\; (\alpha a q - a)p^n + 1$$

And hence $(f+p^nS)(g+p^nS) = 1+p^nS$ which implies $x^{-1} = g+p^nS$ and in particular $x \in R^*$, a contradiction. Hence there has to be some $i \in 1\ldots r$ such that $p \approx q_i$. And therefore we find $p \approx q_i \mid f$ such that $p \mid f$, or in other words again $f \in (p+p^nS)R$. Thus we got

$$\text{NIL}(R) \;=\; \text{ZD}(R) \;=\; R \setminus R^* \;=\; (p+p^nS)\,R$$

Now consider any prime ideal $\mathfrak{p} \trianglelefteq_{\text{i}} R$, then it is clear that $\text{NIL}(R) \subseteq \mathfrak{p} \subseteq R \setminus R^*$. But by the equality $\text{NIL}(R) = R \setminus R^*$ this means $\mathfrak{p} = \text{NIL}(R)$. Therefore $\text{NIL}(R)$ is the one and only prime ideal of R. But $\text{NIL}(R)$ already is maximal - if $\text{NIL}(R) \subset \mathfrak{a} \trianglelefteq_{\text{i}} R$, then there is some $a \in \mathfrak{a} \cap R^*$ and hence $\mathfrak{a} = R$. Thus we have also proved the second equality

$$\text{Spec}(R) \;=\; \text{Smax}(R) \;=\; \{\,\text{NIL}(R)\,\}$$

(vi) We will prove the claim in several steps: (1) given any commutative ring R and any ideal $\mathfrak{a} \trianglelefteq_{\text{i}} R$ let us first denote the following set

$$X_n(R,\mathfrak{a}) \;:=\; \{\,\mathfrak{p} \in \text{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p},\ \#R/\mathfrak{p} \leq n\,\}$$

Then it is clear that $\mathfrak{a} \subseteq \mathfrak{b} \implies X_n(R,\mathfrak{b}) \subseteq X_n(R,\mathfrak{a})$ (because if we are given $\mathfrak{p} \in X_n(R,\mathfrak{b})$, then $\mathfrak{a} \subseteq \mathfrak{b} \subseteq \mathfrak{p}$ and hence $\mathfrak{a} \subseteq \mathfrak{p}$, such that $\mathfrak{p} \in X_n(R,\mathfrak{a})$). Further $X_n(R,\mathfrak{a}\,\mathfrak{b}) \subseteq X_n(R,\mathfrak{a}) \cup X_n(R,\mathfrak{b})$ (because if we are given $\mathfrak{p} \in X_n(R,\mathfrak{a}\,\mathfrak{b})$ then $\mathfrak{a}\,\mathfrak{b} \subseteq \mathfrak{p}$ and as $\mathfrak{p}$ is prime this implies $\mathfrak{a} \subseteq \mathfrak{p}$ or $\mathfrak{b} \subseteq \mathfrak{p}$ such that $\mathfrak{p} \in X_n(R,\mathfrak{a})$ or $\mathfrak{p} \in X_n(R,\mathfrak{b})$). Now suppose $\mathfrak{a} \subseteq \mathfrak{b} \trianglelefteq_{\text{i}} R$, then we will prove

$$\#X_n(R,\mathfrak{b}) \;=\; \#X_n\left(R\Big/_{\mathfrak{a}}, \mathfrak{b}\Big/_{\mathfrak{a}}\right)$$

This is clear once we prove that $\mathfrak{p} \mapsto \mathfrak{p}/\mathfrak{a}$ is a bijection from $X_n(R,\mathfrak{b})$ to $X_n(R/\mathfrak{a},\mathfrak{b}/\mathfrak{a})$. But by the correspondence theorem (1.66) (and the remarks following it) $\overline{\mathfrak{p}} \trianglelefteq_{\text{i}} R/\mathfrak{a}$ is prime if and only if $\overline{\mathfrak{p}} = \mathfrak{p}/\mathfrak{a}$ for some $\mathfrak{p} \trianglelefteq_{\text{i}} R$ prime, with $\mathfrak{a} \subseteq \mathfrak{p}$. And due to the correspondence theorem we also have $\mathfrak{b} \subseteq \mathfrak{p}$ if and only if $\mathfrak{b}/\mathfrak{a} \subseteq \mathfrak{p}/\mathfrak{a}$. Finally we've got the third isomorphism theorem (1.83.(iv)) which provides the isomorphy $R/\mathfrak{p} \;\cong_{\text{r}}\; (R/\mathfrak{a})/(\mathfrak{p}/\mathfrak{a})$. In particular we have $\#R/\mathfrak{p} = \#(R/\mathfrak{a})/(\mathfrak{p}/\mathfrak{a})$. Thus $\mathfrak{p} \mapsto \mathfrak{p}/\mathfrak{a}$ is well-defined and surjective. But the injectivity is clear (by the correspondence theorem) and hence it is bijective. In a second step (2) let us now denote the set

$$\mathcal{A} \;:=\; \{\,\mathfrak{a} \trianglelefteq_{\text{i}} R \mid \#X_n(R,\mathfrak{a}) = \infty\,\}$$

Suppose $\mathcal{A} \neq \emptyset$ was non-empty, then (as R is noetherian) there would be a maximal element $\mathfrak{a}^* \in \mathcal{A}^*$. We now claim that this maximal element $\mathfrak{a}^*$ is prime. It is clear, that $\mathfrak{a}^* \neq R$, as $R/R = 0$ has not a single prime ideal, in particular $\#X_n(R,R) = 0$. Thus suppose there would be some $a, b \in R$ such that $ab \in \mathfrak{a}^*$ but $a, b \notin \mathfrak{a}^*$. Then we let $\mathfrak{a} := \mathfrak{a}^* + aR$ and $\mathfrak{b} := \mathfrak{a}^* + bR$ and thereby get $\mathfrak{a}^* \subset \mathfrak{a}, \mathfrak{b}$ and $\mathfrak{a}\,\mathfrak{b} \subseteq \mathfrak{a}^*$. Thus by the inclusions in (1) we would find

$$X_n(R,\mathfrak{a}^*) \;\subseteq\; X_n(R,\mathfrak{a}\,\mathfrak{b}) \;\subseteq\; X_n(R,\mathfrak{a}) \cup X_n(R,\mathfrak{b})$$

But as $\mathfrak{a}^*$ is maximal in $\mathcal{A}$ we have $\mathfrak{a}, \mathfrak{b} \notin \mathcal{A}$. That is both $X_n(R,\mathfrak{a})$ and $X_n(R,\mathfrak{b})$ are finite. Thus by the above inclusion $X_n(R,\mathfrak{a}^*)$ is finite, too, in contradiction to $\mathfrak{a}^* \in \mathcal{A}$ - thus $\mathfrak{a}^*$ is prime. For

the third step (3) let $Q := R/\mathfrak{a}^*$, then by (2) Q is an integral domain. And if $0 \neq \mathfrak{u} \trianglelefteq_{\mathrm{i}} Q$ is a non-zero ideal, then by the correspondence therorem there is some ideal $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{a}^* \subset \mathfrak{b}$ such that $\mathfrak{u} = \mathfrak{b}/\mathfrak{a}^*$. But as $\mathfrak{a}^*$ has been maximal the equality in (1) yields

$$\#X_n(Q,\mathfrak{u}) \;=\; X_n\left(R\Big/_{\mathfrak{a}^*}, \mathfrak{b}\Big/_{\mathfrak{a}^*}\right) \;=\; \#X_n(R,\mathfrak{b}) \;<\; \infty$$

(4) the same reasoning yields $\#X_n(Q,0) = \#X_n(R,\mathfrak{a}^*) = \infty$, such that Q is infinite (if it was finite, that so was its spectrum and hence the subset $X_n(Q,0)$ was finite as well). Thus we may choose pairwise distinct elements $f_1,\ldots,f_{n+1} \in Q$ and let

$$f \;:=\; \prod_{i\neq j}(f_i - f_j) \;\in\; Q$$

as $f_i - f_j \neq 0$ for any $i \neq j$ and Q is an integral domain we have $f \neq 0$ as well. Now consider any prime ideal $\mathfrak{q} \trianglelefteq_{\mathrm{i}} Q$, if we have $f \notin \mathfrak{q}$ then (as $\mathfrak{q}$ is an ideal) for any $i \neq j \in 1\ldots n+1$ we have $f_i - f_j \notin \mathfrak{q}$. Thus for any $i \neq j \in 1\ldots n+1$ we have $f_i + \mathfrak{q} \neq f_j + \mathfrak{q}$. That is $Q/\mathfrak{q}$ contains (at least) $n+1$ distinct elements and hence $\mathfrak{q} \notin X_n(Q,0)$. Thus for any $\mathfrak{q} \in X_n(Q,0)$ we necessarily have $f \in \mathfrak{q}$ and hence

$$X_n(Q,0) \;=\; X_n(Q,fQ)$$

But as $f \neq 0$ we have $fQ \neq 0$ such that (3) yields $\#X_n(Q,fQ) < \infty$. By the equalities above this means $\infty = \#X_n(R,\mathfrak{a}^*) = \#X_n(Q,0) = X_n(Q,fQ) < \infty$ a contradiction. This means that our assumption $\mathcal{A} \neq \emptyset$ has to be false. In other words $\mathcal{A} = \emptyset$ and in particular $0 \notin \mathcal{A}$. That is $\#X_n(R,0) < \infty$ which is a trivial reformulation of the claim.

□

Proof of (2.112):
The implications (a) $\Longrightarrow$ (b) and (a) $\Longrightarrow$ (c) are trivial. Thus it only remains to check the converse implications. The proof of (c) $\Longrightarrow$ (a) is elementary and has been given in (2.109.(i)). Yet (b) $\Longrightarrow$ (a) requires knowledge of group actions (which will be presented in book 2, or any other standard text on algebra) and cyclotomic fields (which also will be presented in book 2, or any standard text on Galois theory). Never the less we want to give a proof of (b) $\Longrightarrow$ (a) and the reader is asked to refer to the sources given for the statements not contained in this text:

Let us regard the multiplicative group $F^* = F \setminus \{0\}$ (this truly is a group, as F is a skew-field) of F. And let us denote the *center* of the ring F by

$$C \;:=\; \{\, a \in F \mid \forall\, x \in F : ax = xa \,\}$$

It is obvious that $C \leq_{\mathrm{r}} F$ is a commutative sub-ring of F and hence it even is a field. Thus $(F,+)$ is a C-vectorspace under its own multiplication. And as F is finite it clearly has to be finite-dimensional $n := \dim_C F < \infty$. If we denote $q := \#C$ then this implies

$$\#F^* \;=\; \#F - 1 \;=\; \#C^n - 1 \;=\; q^n - 1$$

For any $x \in E^*$ let us now denote the *conjugacy class*, the *centralizer* and the centralizer appended by

0, using the notations

$$\begin{aligned} \mathrm{con}(x) &:= \left\{ yxy^{-1} \mid y \in E^* \right\} \\ \mathrm{CEN}(x) &:= \{ y \in E^* \mid xy = yx \} \\ C(x) &:= \{ y \in E \mid xy = yx \} \end{aligned}$$

It is well-known from group theory that the conjugacy classes $\mathrm{con}(x)$ form a partition of F^* and that $\mathrm{con}(a) = \{ a \}$ for any $a \in C$. Thus let us denote by $X \subseteq F \setminus C$ a representing system of the conjugacy classes, that is $X \longleftrightarrow \{ \mathrm{con}(x) \mid x \in F \setminus C \}$ under $x \mapsto \mathrm{con}(x)$. As the conjugacy classes form a partition of F^* we find the equality

$$\begin{aligned} q^n - 1 \;=\; \#F^* &= \sum_{0 \neq a \in C} \#\mathrm{con}(a) + \sum_{x \in X} \#\mathrm{con}(x) \\ &= \#C^* + \sum_{x \in X} \#\mathrm{con}(x) \\ &= (q-1) + \sum_{x \in X} \#\mathrm{con}(x) \end{aligned}$$

It is clear that $(C(x), +)$ is a subgroup of the additive group $(F, +)$. But it even is a C-subspace of F, we denote its (finite) dimension by $n(x) := \dim_C C(x)$, then we get

$$\#\mathrm{CEN}(x) \;=\; \#C(x) - 1 \;=\; \#C^{n(x)} - 1 \;=\; q^{n(x)} - 1$$

We now apply the orbit formula $\#F^* = \#\mathrm{con}(x) \cdot \#\mathrm{CEN}(x)$. Yet as $\#\mathrm{con}(x)$ is an iteger we find the divisibility $\#\mathrm{CEN}(x) \mid \#F^*$. Using division with remainder we obtain

$$q^n - 1 : q^{n(x)} - 1 \;=\; q^{n-n(x)} + q^{n-2n(x)} + \cdots + q^{n-r(x)n(x)}$$

As this division leaves no remainder we necessarily find $n = r(x)n(x)$, i.e. $n(x)$ divides n. On the other hand the orbit formula yields

$$\#\mathrm{con}(x) \;=\; \frac{q^n - 1}{q^{n(x)} - 1}$$

Substituting this into our partition formula for the cardinality of F^* we find

$$q^n - 1 \;=\; (q-1) + \sum_{x \in X} \frac{q^n - 1}{q^{n(x)} - 1}$$

This is the point where the cyclotomic polynomials $\Phi_m \in \mathbb{Z}[t]$ come into play. Let $m \in \mathbb{N}$ and $\omega_m := \exp(2\pi i/m) \in \mathbb{C}$, further denote $k \perp m \;:\Longleftrightarrow\; k \in 1 \ldots m$ and $\gcd(k, m) = \pm 1$. Then the m-th *cyclotomic polynomial* is defined to be

$$\Phi_m \;:=\; \prod_{k \perp m} (t - \omega_m^k)$$

In book 2 it will be shown that $\Phi_m \in \mathbb{Z}[t]$ has integer coefficients in fact and (if we denote $d \mid m \;:\Longleftrightarrow\; d \in 1 \ldots m$ and $d \mid m$) satisfies

$$\prod_{d \mid m} \Phi_d \;=\; t^m - 1$$

We now assume $F \neq C$ (i.e. F is not commutative) and regard any $x \in X$. It is clear that we find $\Phi_n(q) \mid q^n - 1$. But as $x \notin C$ we get $\#\mathrm{con}(x) \neq 1$ and hence $n \neq n(x)$ on the other hand we have seen $n(x) \mid n$ and hence

$$(t^{n(x)} - 1)\Phi_n \;=\; \left(\prod_{d \mid n(x)} \Phi_d\right)\Phi_n \;\Big|\; \prod_{d \mid n} \Phi_d \;=\; t^n - 1$$

Thus we get $\Phi_n(q) \mid (q^n - 1)/(q^{n(x)} - 1)$, too and substituting this and $\Phi_n(q) \mid q^n - 1$ into the equation of the partition we obtain

$$\Phi_n(q) \;\Big|\; (q^n - 1) - \sum_{x \in X} \frac{q^n - 1}{q^{n(x)} - 1} \;=\; q - 1$$

In particular we get $\Phi_n(q) \leq q - 1$. But this clearly cannot be - as $q \geq 2$ (at least 0 and $1 \in C$) we see by the triange inequality that $|q - 1| < |q - w_n^k|$ for any $k \in 1 \ldots n - 1$. Hence we arrived at a contradiction (to $C \neq F$)

$$q - 1 \;\geq\; |\Phi_n(q)| \;=\; \prod_{k \perp n} |q - \omega_n^k| \;>\; \prod_{k \perp n} |q - 1| \;\geq\; q - 1$$

□

Proof of (2.114):

(i) R^* and $\mathrm{NZD}(R)$ are multiplicatively closed, due to (1.47). And if conversely $uv \in R^*$, then there is some $a \in R$ such that $1 = a(uv) = u(av)$. Hence we also have $u \in R^*$. Likewise, if $uv \in \mathrm{NZD}(R)$ and $a \in R$ then $au = 0$ implies $auv = 0$ and hence $a = 0$ such that $u \in \mathrm{NZD}(R)$.

(iii) $1 = 1 \cdot 1 \in UV$ is clear and if u, $u' \in U$ and v, $v' \in V$, then for any uv and $u'v' \in UV$ we get $(uv)(u'v') = (uu')(vv') \in UV$ again.

(iv) Immediate: if a and $b \in \mathfrak{a}$ then $(1 + a)(1 + b) = 1 + (a + b + ab) \in 1 + \mathfrak{a}$.

(v) Clearly $1 \in \varphi(U)$, as $1 \in U$ and $\varphi(1) = 1$. And if p, $q \in \varphi(U)$ then there are u, $v \in U$ such that $p = \varphi(u)$ and $q = \varphi(v)$. Hence $pq = \varphi(u)\varphi(v) = \varphi(uv) \in \varphi(U)$ since $uv \in U$. Likewise $1 \in \varphi^{-1}(V)$ is clear, as $\varphi(1) = 1 \in V$. And if u, $v \in \varphi^{-1}(V)$ then $\varphi(u)$, $\varphi(v) \in V$. thereby we get $uv \in \varphi^{-1}(V)$ from $\varphi(uv) = \varphi(u)\varphi(v) \in V$. So let us finally suppose V is saturated and $uv \in \varphi^{-1}(V)$. Then $\varphi(uv) = \varphi(u)\varphi(v) \in V$ implies $\varphi(u) \in V$ and hence $u \in \varphi^{-1}(V)$, as well.

(vi) As $\mathcal{U} \neq \emptyset$ there is some $1 \in U \in \mathcal{U}$ and hence $1 \in \bigcup \mathcal{U}$. And if now $uv \in \bigcup \mathcal{U}$ then there are some U, $V \in \mathcal{U}$ such that $u \in U$ and $v \in V$. As $\mathcal{U}$ is a chain we may assume $U \subseteq V$ and hence $u \in V$. This yields $uv \in V$ and hence $uv \in \bigcup \mathcal{U}$.

(vii) Since $1 \in U$ for any $U \in \mathcal{U}$ we also have $1 \in \bigcap \mathcal{U}$. And if u, $v \in \bigcap \mathcal{U}$, then u, $v \in U$ for any $U \in \mathcal{U}$. Thereby $uv \in U$, as U is multiplicatively closed and hence $uv \in \bigcap \mathcal{U}$. Likewise if any $U \in \mathcal{U}$ is saturated, then $uv \in \bigcap \mathcal{U}$ implies $uv \in U$ and hence $u \in U$ for any $U \in \mathcal{U}$. And the latter translates into $u \in \bigcap \mathcal{U}$ again.

(viii) Clearly $1 = u^0 \in U$ and if u^i and $u^j \in U$ then also $u^i u^j = u^{i+j} \in U$. That is U is a multiplicatively closed set with $u \in U$. And if conversely $V \subseteq R$ is any multiplicatively closed set with $u \in V$,

then by induction on k we also find $u^k \in V$ and hence $U \subseteq V$. Together this proves, that U is the smallest multiplicatively closed set containing u.

(ix) Let us define $\overline{U}$ to be the set given, then we need to show that $\overline{U}$ is the intersection of all saturated multiplicatively closed subsets $V \subseteq R$ containing U. "$\subseteq$": Thus consider any saturated multiplicatively closed $V \subseteq R$ with $U \subseteq V$. If now $a \in \overline{U}$ then there are $b \in R$ and $u, v \in U$ such that $uab = uv \in U \subseteq V$. In particular $a(ub) = uab \in V$ and as V is saturated this implies $a \in V$. Hence $\overline{U} \subseteq V$ is contained in any such V. "$\supseteq$": If $a \in U$ that $1a1 = 1a$ and hence $a \in \overline{U}$. Hence we have $U \subseteq \overline{U}$ so it remains to prove that $\overline{U}$ is saturated multiplicatively closed. Thus consider a and $a' \in \overline{U}$, that is $uab = uv$ and $u'a'b' = u'v'$ for sufficient b, $b' \in R$ and u, v, u', $v' \in U$. Then $(uu')aa'(bb') = (uu')(vv')$ and hence $aa' \in \overline{U}$, as uu', $vv' \in U$. Conversely suppose $aa' \in \overline{U}$, that is $u(aa')b = uv$ for sufficient $b \in R$, u, $v \in U$. Then $ua(a'b) = u(aa')b = uv$ and hence $a \in \overline{U}$.

□

Proof of (2.115):
We first prove (b) $\implies$ (a): consider any prime ideal $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$, then $1 \in R \setminus \mathfrak{p}$, as $1 \in \mathfrak{p}$ would imply $\mathfrak{p} = R$ which is disallowed. And as $\mathfrak{p}$ is both, *prime* and an *ideal* we get the following equivalence for all u, $v \in R$

$$uv \in \mathfrak{p} \iff u \in \mathfrak{p} \text{ or } v \in \mathfrak{p}$$

Hence if we go to complements (i.e. if we negate this equivelency) then we find that $R \setminus \mathfrak{p}$ is a saturated multiplicative set, since

$$uv \in R \setminus \mathfrak{p} \iff u \in R \setminus \mathfrak{p} \text{ or } v \in R \setminus \mathfrak{p}$$

And from this we find that $R \setminus \bigcup \mathcal{P}$ is a saturated multiplicative set, as it is the intersection of such sets $R \setminus \mathfrak{p}$ for $\mathfrak{p} \in \mathcal{P}$, formally

$$R \setminus \bigcup \mathcal{P} = R \setminus \bigcup_{\mathfrak{p} \in \mathcal{P}} \mathfrak{p} = \bigcap_{\mathfrak{p} \in \mathcal{P}} R \setminus \mathfrak{p}$$

Next we prove (a) $\implies$ (a): fix $a \in R \setminus U$ then also $aR \subseteq R \setminus U$: consider $b \in R$, then $ab \in U$ - because of the saturation of U - would imply $a \in U$, in contradiction to $a \notin U$. And as U is multiplicatively closed we max choose an ideal $\mathfrak{p}(a)$ maximal among the ideals $\mathfrak{b}$ with $aR \subseteq \mathfrak{b} \subseteq R \setminus U$. And this $\mathfrak{p}(a)$ is prime (for all this refer to (2.18.(iv))). Thus we get

$$R \setminus U \subseteq \bigcup_{a \notin U} aR \subseteq \bigcup_{a \notin U} \mathfrak{p}(a) \subseteq R \setminus U$$

$$\implies U = R \setminus \bigcup \{ \mathfrak{p}(a) \mid a \notin U \}$$

□

Proof of (2.116):

- We will first prove that $\sim$ is an equivalence relation: the reflexivity is due to $1 \in U$, as $u1a = u1a$ implies $(u, a) \sim (u, a)$. For the symmetry suppose $(u, a) \sim (v, b)$, i.e. there is some $w \in U$ such that $vwa = uwb$. As $=$ is symmetric we get $uwb = vwa$ and this is $(v, b) \sim (u, a)$ again. To finally prove the transitivity we regard $(u, a) \sim (v, b)$ and $(v, b) \sim (w, c)$. That is there are p, $q \in U$ such that $pva = pub$ and $qwb = qvc$. Since p, q and $v \in U$ we also have $pqv \in U$. Now

compute $(pqv)wa = qw(pva) = qw(pub) = pu(qwb) = pu(qvc) = (pqv)uc$, this yields that truly $(u,a) \sim (w,c)$ are equivalent, too.

- Next we need to check that the operations $+$ and $\cdot$ are well-defined. Suppose $a/u = a'/u'$ and $b/v = b'/v'$ that is there are p and $q \in U$ such that $pu'a = pua'$ and $qv'b = qvb'$. Then we let $w := pq \in U$ and compute

$$\begin{aligned} u'v'w(av+bu) &= vv'q(pu'a) + uu'p(qv'b) \\ &= vv'q(pua') + uu'p(qvb') \\ &= uvw(a'v' + u'b') \\ u'v'wab &= (pu'a)(qv'b) \\ &= (pua')(qvb') \\ &= uvwa'b' \end{aligned}$$

 That is $(a/u)+(b/v) = (av+bu)/uv = (a'v'+b'u')/u'v' = (a'/u')+(b'/v')$ and $(a/u)(b/v) = ab/uv = a'b'/u'v' = (a'/u')(b'/v')$ respectively. And this is just the well-definedness of sum and product.

- Next it would be due to verify that $U^{-1}R$ thereby becomes a commutative ring. That is we have to check that $+$ and $\cdot$ are associative, commutative and satisfy the distributivity law. Further that for any $a/u \in U^{-1}R$ we have $a/u + 0/1 = a/u$ and $a/u + (-a)/u = 0/1$ and finally that $a/u \cdot 1/1 = a/u$. But this can all be done in straightforward computations, that we wish to omit here.

- It is obvious that thereby κ becomes a homomorphism of rings, $\kappa(0) = 0/1$ is the zero-element and $\kappa(1) = 1/1$ is the unit element. Further $\kappa(a+b) = (a+b)/1 = (a1+b1)/1\cdot 1 = a/1 + b/1 = \kappa(a) + \kappa(b)$ and $\kappa(ab) = ab/1 = ab/1\cdot 1 = (a/1)(b/1) = \kappa(a)\kappa(b)$.

- Next we wish to prove that κ is injective, if and only if $U \subseteq \text{NZD}(R)$. To do this we take a look at the kernel of κ

$$\begin{aligned} \ker(\kappa) &= \{\, a \in R \mid a/1 = 0/1 \,\} \\ &= \{\, a \in R \mid \exists\, u \in U : au = 0 \,\} \end{aligned}$$

 By (1.80.(i)) κ is injective iff $\ker(\kappa) = \{0\}$. That is iff for any $u \in U$ we get $au = 0 \implies a = 0$. And this is just a reformulation of $U \subseteq \text{NZD}(R)$.

- So it remains to prove that κ is bijective if and only if $U \subseteq R^*$. First suppose $U \subseteq R^* \subseteq \text{NZD}(R)$ by (1.47). Then as we have just seen κ is injective. Now consider any $a/u \in U^{-1}R$, then

$$\frac{a}{u} = \frac{au^{-1}u}{u} = \frac{au^{-1}}{1} = \kappa(au^{-1}) \in \operatorname{im}(\kappa)$$

 Hence we found that κ also is surjective. Conversely suppose that κ is bijective. In particular κ is injective and hence $U \subseteq \text{NZD}(R)$. But κ also is surjective, that is for any $u \in U$ there is some $b \in R$ such that $1/u = \kappa(b) = b/1$. That is there is some $w \in U$ such that $w = uwb$. Equivalently

$w(ub-1)=0$, but as $w \in \text{NZD}(R)$ this implies $ub=1$ and hence $u \in R^*$. As u has been arbitrary we found $U \subseteq R^*$.

□

Proof of (3.121):

- We will first prove that $\sim$ is an equivalence relation: the reflexivity is due to $1 \in U$, as $u1x = u1x$ implies $(u,x) \sim (u,x)$. For the symmetry suppose $(u,x) \sim (v,y)$, i.e. there is some $w \in U$ such that $vwx = uwy$. As $=$ is symmetric we get $uwy = vwx$ and this is $(v,y) \sim (u,x)$ again. To finally prove the transitivity we regard $(u,x) \sim (v,y)$ and $(v,y) \sim (w,z)$. That is there are p, $q \in U$ such that $pvx = puy$ and $qwy = qvz$. Since p, q and $v \in U$ we also have $pqv \in U$. Now compute $(pqv)wx = qw(pvx) = qw(puy) = pu(qwy) = pu(qvz) = (pqv)uz$, this yields that truly $(u,x) \sim (w,z)$ are equivalent, too.

- Next we need to check that the addition is well-defined. Suppose $x/u = x'/u'$ and $y/v = y'/v'$ that is there are p and $q \in U$ such that $pu'x = pux'$ and $qv'y = qvy'$. Then we let $w := pq \in U$ and compute

$$\begin{aligned} u'v'w(vx+uy) &= vv'q(pu'x) + uu'p(qv'y) \\ &= vv'q(pux') + uu'p(qvy') \\ &= uvw(v'x' + u'y') \end{aligned}$$

 That is $(x/u)+(y/v) = (vx+uy)/uv = (v'x'+u'y')/u'v' = (x'/u')+(y'/v')$ which is the well-definedness of the addition. For the R-scalar multiplication we need to show that $a(x/u) = ax/u = ax'/u' = a(x'/u')$. But by taking $w = p$ this is easy to see

$$pu'(ax) \;=\; a(pu'x) \;=\; a(pux') \;=\; pu(ax')$$

 which is the equivalence $(u,ax) \sim (u',ax')$. Likewise for the $U^{-1}R$-scalar multiplication we need to show that $(a/u)(y/v) = ay/uv = ay'/uv' = (a/u)(y'/v')$. But taking $w = q$ this time, we prove the equivalence $(uv,ay) \sim (uv',ay')$ by computing

$$q(uv')(ay) \;=\; au(qv'y) \;=\; au(qvy') \;=\; q(uv)(ay')$$

- Next we have to prove that $U^{-1}M$ truly becomes an $U^{-1}R$-module. We start by proving the properties of a commutative group: associativity, commutativity and the existence of the neutral element $0/1$ and the inverse element $-x/u$ of x/u

$$\begin{aligned} \left(\frac{x}{u}+\frac{y}{v}\right)+\frac{z}{w} &= \frac{vx+uy}{uv}+\frac{z}{w} \\ &= \frac{vwx+uwy+uvz}{uvw} \\ &= \frac{x}{u}+\frac{wy+vz}{vw} \\ &= \frac{x}{u}+\left(\frac{y}{v}+\frac{z}{w}\right) \\ \frac{x}{u}+\frac{y}{v} &= \frac{vx+uy}{uv} = \frac{uy+vx}{vu} \end{aligned}$$

$$\begin{aligned} &= \frac{y}{v}+\frac{x}{u} \\ \frac{x}{u}+\frac{0}{1} &= \frac{1x+u0}{u\cdot 1} = \frac{x}{u} \\ \frac{x}{u}+\frac{-x}{u} &= \frac{ux+u(-x)}{u\cdot u} = \frac{x+(-x)}{u} \\ &= \frac{0}{u} = \frac{0}{1} \end{aligned}$$

Next we have to check the compatibility conditions of the scalar multiplication with the addition on $U^{-1}M$. Again this can be done in straightforward computations

$$\begin{aligned} \frac{a}{u}\left(\frac{y}{v}+\frac{z}{w}\right) &= \frac{a}{u}\frac{wy+vz}{vw} = \frac{a(wy+vz)}{uvw} \\ &= \frac{uway+uvaz}{uvuw} = \frac{ay}{uv}+\frac{az}{uw} \\ &= \frac{a}{u}\frac{y}{v}+\frac{a}{u}\frac{z}{w} \\ \left(\frac{a}{u}+\frac{b}{v}\right)\frac{z}{w} &= \frac{va+ub}{uv}\frac{z}{w} = \frac{vaz+ubz}{uvw} \\ &= \frac{vaz}{vuw}+\frac{ubz}{uvw} = \frac{az}{uw}+\frac{bz}{vw} \\ &= \frac{a}{u}\frac{z}{w}+\frac{b}{v}\frac{z}{w} \\ \left(\frac{a}{u}\frac{b}{v}\right)\frac{z}{w} &= \left(\frac{ab}{uv}\right)\frac{z}{w} = \frac{abz}{uvw} \\ &= \frac{a}{u}\frac{bz}{vw} = \frac{a}{u}\left(\frac{b}{v}\frac{z}{w}\right) \\ \frac{1}{1}\frac{x}{u} &= \frac{1x}{1u} = \frac{x}{u} \end{aligned}$$

- As $\kappa : R \to U^{-1}R : a \mapsto a/1$ is a homomorphism of rings and $U^{-1}M$ is an $U^{-1}R$-module it also becomes an R-module under the following scalar multiplication

$$a\frac{x}{u} = \kappa(a)\frac{x}{u} = \frac{a}{1}\frac{x}{u} = \frac{ax}{u}$$

- Next we would like to show that $\kappa : M \to U^{-1}M : x \mapsto x/1$ is an R-module homomorphism. But this is obvious for any x, $y \in M$ and any $a \in R$ we get: $\kappa(ax) = ax/1 = a(x/1) = a\kappa(x)$ and $\kappa(x+y) = (x+y)/1 = (1x+1y)/(1\cdot 1) = x/1 + y/1 = \kappa(x)+\kappa(y)$.

- Let us now prove that κ is injective if and only if $U \subseteq \text{NZD}(M)$: note that κ is injective, iff $\ker(\kappa) = 0$ that is if $x/1 = 0/1$ implies that $x = 0$. But by definition $x/1 = 0/1$ means $wx = w0 = 0$ for some $w \in U$. That is κ is injective if and only if U and the set $R \setminus \text{NZD}(M) = \{\, a \in R \mid \exists\, x \in M \text{ such that } x \neq 0 \text{ and } ax = 0 \,\}$ are disjoint. In other words that is $U \subseteq \text{NZD}(M)$.

- Let us finally assume that $U \subseteq R^*$. Then (as $M \neq 0$) it is clear that $U \subseteq \text{NZD}(M)$ such that κ already is injective. It remains to prove the surjectivity. Hence consider any $y/u \in U^{-1}M$. Then we chose $w = 1$ and $x = u^{-1}y$ from which we find $wux = uu^{-1}y = y = wy$ such that $\kappa(x) = x/1 = y/u$. Together we derived the bijectivity of κ.

□

Proof of (3.122):
By definition we have $x/u = 0/1$ iff there is some $w \in U$ such that $1wx = uw0 = 0$. That is if and only if $wx = 0$. Next - due to the commutativity of R - we have $u(vx) = (uv)x = (vu)x$, so choosing $w = 1$ we see that $vx/vu = x/u$. And the third equality calls for induction: for $n = 1$ there is nothing to prove, for $n = 2$ this is precisely the definiton of the addition in $U^{-1}M$: $x_1/u_1 + x_2/u_2 = (u_2x_1 + u_1x_2)/(u_1u_2)$. So for the induction step use the notation of $u = u_1 \dots u_n$ and $\widehat{u}_i = u/u_i$ as introduced in the remark

$$\begin{aligned}\frac{x_1}{u_1} + \dots + \frac{x_n}{u_n} + \frac{x_{n+1}}{u_{n+1}} &= \frac{\widehat{u}_1x_1 + \dots + \widehat{u}_nx_n}{u} + \frac{x_{n+1}}{u_{n+1}} \\ &= \frac{\widehat{u}_1u_{n+1}x_1 + \dots + \widehat{u}_nu_{n+1}x_n + ux_{n+1}}{uu_{n+1}}\end{aligned}$$

So by letting $v := u_1u_2 \dots u_nu_{n+1} = uu_{n+1}$ and $\widehat{v}_i := v/u_i \in U$ we see that the $\widehat{v}_i$ appear as the coefficients of the x_i again, e.g. we have $\widehat{v}_1 = \widehat{u}_1u_{n+1}$ and $\widehat{v}_{n+1} = u$. Hence we have just proved the induction step, that is $x_1/u_1 + x_2/u_2 + \dots + x_{n+1}/u_{n+1} = (\widehat{v}_1x_1 + \widehat{v}_2x_2 + \dots + \widehat{v}_{n+1}x_{n+1})/v$. □

Proof of (3.124):

(i) Let us first check the homomorphism property of κ: Clearly κ commutes with the addition so we only have to check that is also commutes with the scalar multiplication. By definition $\kappa : (a/u)x \mapsto ((a/u)x)/1$, but $((a/u)x)/1 = ((a/1)x)/u$ as by construction of the scalar multiplication on M_R we have $u(a/u)x = (u/1)(a/u)x = (ua/u)x = (a/1)x$. Now $((a/u)x)/1 = ((a/1)x)/u = (ax/u) = (a/u)(x/1)$ completes the S-linearity.

The surjectivity of κ is a special case of this: Given any $x/u \in U^{-1}M_R$ we get (using $a = 1$) $\kappa((1/u)x) = ((1/1)x)/u = x/u$. And then we also find the injectivity of κ, as $x/1 = 0/1$ means $wx = 0 \in M$ for some $w \in U$ and therefore $0 = (1/w)(wx) = (1/1)x = x$.

(ii) The R-linearity of λ_u is clear and as $\lambda_u(x) = ux = 0$ implies $0 = (1/u)(ux) = (u/u)x = (1/1)x = x$ we see that λ_u also in injective. And as $\lambda_u((1/u)x) = u(1/u)x = (u/u)x = (1/1)x = x$ it is surjective, as well.

(iii) If $\varphi : M \to N$ is S-linear then it also is R-linear, as in general we find $\varphi(ax) = \varphi((a/1)x) = (a/1)\varphi(x) = a\varphi(x)$. For the converse implication we will need $U/1 \subseteq \text{NZD}(N)$. Let us compute

$$\begin{aligned}\frac{u}{1}\varphi\left(\frac{a}{u}x\right) &= u\varphi\left(\frac{a}{u}x\right) = \varphi\left(u\frac{a}{u}x\right) = \varphi\left(\frac{ua}{u}x\right) \\ &= \varphi\left(\frac{a}{1}x\right) = \varphi(ax) = a\varphi(x) = \frac{a}{1}\varphi(x) \\ &= \frac{u}{1}\frac{a}{u}\varphi(x) = \frac{u}{1}\left(\frac{a}{u}\varphi(x)\right)\end{aligned}$$

That is we have $(u/1)y = 0$ for $y = \varphi((a/u)x) - (a/u)\varphi(x) \in N$. But as $u/1 \in \text{NZD}(N)$ this means $y = 0$ and hence $\varphi((a/u)x) = (a/u)\varphi(x)$, which is the S-linearity of φ.

□

Proof of (3.125):

(ii) It is quite easy to see that $U^{-1}\varphi$ is well-defined: if $x/u = y/v$ then there is some $w \in U$ such that $wvx = wuy$ such that $wv\varphi(x) = \varphi(wvx) = \varphi(wuy) = wu\varphi(y)$ which again implies $\varphi(x)/u = \varphi(y)/v$. Also it is easy to see, that $U^{-1}\varphi$ is a homomorphism of R-modules again

$$\begin{aligned} U^{-1}\varphi\left(a\frac{x}{u} + \frac{y}{u}\right) &= U^{-1}\varphi\left(\frac{ax+y}{u}\right) = \frac{\varphi(ax+y)}{u} \\ &= \frac{a\varphi(x)+\varphi(y)}{u} = a\frac{x}{u} + \frac{y}{u} \\ &= a\,U^{-1}\varphi\left(\frac{x}{u}\right) + U^{-1}\varphi\left(\frac{y}{u}\right) \end{aligned}$$

So it remains to verify the identities of the kernel and image of $U^{-1}\varphi$. First of all, for any $u \in U$ and any $x \in M$ we have $U^{-1}\varphi(x/u) = \varphi(x)/u \in U^{-1}(\mathrm{im}(\varphi))$. And conversely if $y/u \in U^{-1}(\mathrm{im}(\varphi))$ then there are some $v \in U$ and $x \in M$ such that $y/v = \varphi(x)/u$. That is $y/v = U^{-1}\varphi(x/u) \in \mathrm{im}(U^{-1}\varphi)$. Altogether we have

$$\mathrm{im}\left(U^{-1}\varphi\right) = U^{-1}\mathrm{im}(\varphi)$$

Also $x/u \in U^{-1}\mathrm{kn}(\varphi)$ this means that there are some $v \in U$ and $k \in \mathrm{kn}(\varphi)$ such that $x/u = k/v$. Therefore $U^{-1}\varphi(x/u) = U^{-1}\varphi(k/v) = \varphi(k)/v = 0/v = 0/1 = 0$ such that $x/u \in \mathrm{kn}(U^{-1}\varphi)$ again. And conversely for any $u \in U$ and any $x \in M$ we have $x/u \in \mathrm{kn}(U^{-1}\varphi)$ if and only if $0/1 = U^{-1}\varphi(x/u) = \varphi(x)/u$, which is $0 = w\varphi(x) = \varphi(wx)$ again, for some $w \in U$. That is $k := wx \in \mathrm{kn}(\varphi)$, so letting $v := wu$ we get $x/u = wx/wu = k/v \in U^{-1}\mathrm{kn}(\varphi)$. Altogether we also have

$$\mathrm{kn}\left(U^{-1}\varphi\right) = U^{-1}\mathrm{kn}(\varphi)$$

(i) We have already seen that $U^{-1}P$ is an R-module. And as $P \subseteq M$ we may regard the following map

$$U^{-1}P \hookrightarrow U^{-1}M \,:\, \frac{x}{u} \mapsto \frac{x}{u}$$

Note that this truly is a map, as the equivalence class of (u,x) has changed from a subset of $U \times P$ to a subset of $U \times M$. However it is obvious, that this map is both well-defined and injective as $(u,x) \sim (v,y)$ is the same in $U \times P$ and $U \times M$. Hence $U^{-1}P$ can be identified by its image under this embedding

$$U^{-1}P \cong_{\mathrm{m}} \left\{ \frac{x}{u} \mid x \in P, u \in U \right\}$$

So in the following we will regard $U^{-1}P' \subseteq U^{-1}M$ as a subset of $U^{-1}M$. Then we may take to the following map

$$\varrho \,:\, U^{-1}M \to U^{-1}(M/P) \,:\, \frac{x}{u} \mapsto \frac{x+P}{u}$$

First of all - using (ii) - ϱ is a well-defined $U^{-1}R$-module homomorphism, as it just is the localization of the canonical homomorphism $x \mapsto x + P$

$$\varrho = U^{-1}\left(M \to {}^{M}\big/_{P} : x \mapsto x + P\right)$$

Also the surjectivity of ϱ is trivial, as $x \in M$ and $u \in U$ can be chosen arbitrarily. And as

$x \mapsto x + P$ trivially has the kernel P we can also evaluate the kernel of ϱ by using (ii) again:

$$\mathsf{kn}(\varrho) \;=\; U^{-1}\mathsf{kn}(x \mapsto x + P) \;=\; U^{-1}P$$

Altogether, using the first isomorphism theorem (3.78.(ii)), ϱ induces the isomorphism of R-modules, that we claimed to exist

$$U^{-1}M \Big/ U^{-1}P \to U^{-1}(M/P) \;:\; \frac{x}{u} + U^{-1}P \mapsto \frac{x+P}{u}$$

(iii) Let us first check the well-definedness of the map given: if $(x_i/u_i) = (y_i/v_i)$ then (for any $i \in I$) there is some $w_i \in U$ such that $w_i v_i x_i = w_i u_i y_i$. Let us now define $w := \prod_{i\in\Omega} w_i$ and $\widehat{w}_i := w/w_i \in U$ as well. That is $w_i\widehat{w}_i = w$. Then multiplying this equation with $\widehat{u}_i\widehat{v}_i\widehat{w}_i$ we get

$$wv\widehat{u}_i x_i \;=\; \widehat{u}_i\widehat{v}_i\widehat{w}_i w_i v_i x_i \;=\; \widehat{u}_i\widehat{v}_i\widehat{w}_i w_i u_i y_i \;=\; wu\widehat{v}_i y_i$$

Composing these equalities for all $i \in I$ we found $wv(\widehat{u}_i x_i) = wu(\widehat{v}_i y_i)$ which yields $(\widehat{u}_i x_i)/u = (\widehat{v}_i y_i)/v$ again. Also it is clear, that $(\widehat{u}_i x_i)$ is contained in the direct *sum* of the M_i because $\widehat{u}_i x_i \neq 0$ disallows $wx_i = 0$ for some $w \in U$ which is $x_i/u_i \neq 0/1$ such that $i \in \Omega$. And the set Ω has been finite by the assumption that (x_i/u_i) comes from the direct *sum* of the $U^{-1}M_i$.

To prove the properties of an $U^{-1}R$-module homomorphism we let $n := \#\Omega$. Then for any $a/v \in U^{-1}R$ we may compute

$$\frac{a}{v}\left(\frac{x_i}{u_i}\right) \;=\; \left(\frac{ax_i}{vu_i}\right) \;\mapsto\; \frac{(\widehat{u}_i v^{n-1} a x_i)}{v^n u} \;=\; \frac{v^{n-1}a(\widehat{u}_i x_i)}{v^n u} \;=\; \frac{a}{v}\frac{(\widehat{u}_i x_i)}{u}$$

$$\left(\frac{x_i}{u_i}\right) + \left(\frac{y_i}{v_i}\right) \;=\; \left(\frac{v_i x_i + u_i y_i}{u_i v_i}\right) \;\mapsto\; \frac{(\widehat{u}_i\widehat{v}_i(v_i x_i + u_i y_i))}{uv}$$

Now we use $\widehat{u}_i u_i = 0$ and $\widehat{v}_i v_i = v$ again to continue with the computation $\widehat{u}_i\widehat{v}_i(v_i x_i + u_i y_i) = v\widehat{u}_i x_i + u\widehat{v}_i y_i$, which ultimately leads to

$$\left(\frac{x_i}{u_i}\right) + \left(\frac{y_i}{v_i}\right) \;\mapsto\; \frac{(v\widehat{u}_i x_i + u\widehat{v}_i y_i)}{uv} \;=\; \frac{(\widehat{u}_i x_i)}{u} + \frac{(\widehat{v}_i y_i)}{v}$$

Next we prove the injectivity of the homomorphism: suppose we have $(\widehat{u}_i x_i)/u = (\widehat{v}_i y_i)/v$ that is $wv(\widehat{u}_i x_i) = wu(\widehat{v}_i y_i)$ for some $w \in U$. That is for any $i \in I$ we have

$$wv\widehat{u}_i x_i \;\; = wu\widehat{v}_i y_i$$

Let us now define $w_i := \widehat{u}_i\widehat{v}_i w \in U$, then the above equation turns into $w_i v_i x_i = w_i u_i y_i$ which is $x_i/u_i = y_i/v_i$. And as $i \in I$ has been arbitrary this is $(x_i/u_i) = (y_i/v_i)$ again. It remains to prove the surjectivity of the homomorphism: thus consider any $(y_i)/v$ where $y_i \in M_i$. Then we let $x_i := y_i$ and $\Omega := \{\, i \in I \mid y_i \neq 0 \,\}$. If $i \in \Omega$ we take $u_i := v \in U$, else $u_i := 1 \in U$. Again we let $n := \#\Omega$ (which is finite) then $u = v^n$ and $\widehat{u}_i = v^{n-1}$ for any $i \in \Omega$. Then we get

$$\left(\frac{x_i}{u_i}\right) \;\mapsto\; \frac{(\widehat{u}_i x_i)}{u} \;=\; \frac{(v^{n-1}x_i)}{v^n} \;=\; \frac{(x_i)}{v} \;=\; \frac{(y_i)}{v}$$

□

Proof of (3.127):

- We first have to check the well-definedness of $\bar{k}$, that is given an $U^{-1}R$-sub-module Z of $U^{-1}M$ we need to verify that $P := \bar{k}(Z)$ truly is an R-sub-module of M, thereby $P = \{ x \in M \mid x/1 \in Z \}$. To do this one might argue, that κ is an R-module homomorphism an $P = \kappa^{-1}(Z)$ is just the preimage of Z or one might turn to a straightforward computation: First of all we have $0 \in P$, since $0/1 = 0 \in Z$. Also if x and $y \in P$, that is $x/1$ and $y/1 \in Y$ then $(x+y)/1 = x/1 + y/1 \in Z$ and $(ax)/1 = (a/1)(x/1) \in Z$ such that $x+y$ and $ax \in P$ again.

- Next we check the well-definedness of k, that is given an R-sumbodule P of M we need to verify that $Z := k(P)$ truly is an $U^{-1}R$-sub-module of $U^{-1}M$,thereby $Z = \{ x/u \mid x \in P, u \in U \}$. It is clear that $0 = 0/1 \in Z$ since $0 \in P$ and considering x/u and $y/v \in Z$ and any $a/w \in U^{-1}R$ we also get $x/u + y/v = (vx+uy)/uv \in Z$ since $vx + uy \in P$ and $(a/w)(x/u) = ax/uw \in Z$ since $ax \in P$ and $uw \in U$ again.

- So let us now check $k\bar{k} = \mathbb{1}$, that is for any $U^{-1}R$-sub-module Z of $U^{-1}M$ we get $k\bar{k}(Z) = Z$. To do this let $P := \bar{k}(Z)$, then by definition of k and $\bar{k}$ we get the following equality

$$k\bar{k}(Z) \;=\; \left\{ \frac{x}{u} \mid u \in U \text{ and } x \in P \right\} \;=\; \left\{ \frac{x}{u} \mid u \in U \text{ and } x/1 \in Z \right\}$$

 First consider $x/u \in k\bar{k}(Z)$, as we have seen this means $x/1 \in Z$. But as Z is an $U^{-1}R$-module, we hence get $x/u = (1/u)(x/1) \in Z$. Therefore we find the inclusion $k\bar{k}(Z) \subseteq Z$. Conversely if $x/u \in Z$, then $x/1 = (u/1)(x/u) \in Z$ as well, such that we also get $x/u \in k\bar{k}(Z)$.

- Consider any R-sub-module $P \leq_{\mathsf{m}} M$ then by definition of the maps k and $\bar{k}$ we get the following equality of sets

$$\begin{aligned}
\bar{k}k(P) &= \left\{ x \in M \mid x/1 \in \bar{k}(P) \right\} \\
&= \{ x \in M \mid \exists\, p \in P\ \exists\, u \in U : x/1 = p/u \} \\
&= \{ x \in M \mid \exists\, p \in P\ \exists\, u, w \in U : wux = wp \} \\
&= \{ x \in M \mid \exists\, v \in U : vx \in P \}
\end{aligned}$$

 Thereby the last equality can be seen in the following way: if $wux = wp$ then let $v := wu$, then $vx = wux = wp \in P$. Conversely if $vx \in P$ then let $p = vx$ and take $u = v$ and $w = 1$ then $wux = vx = p = wp$. In particular we get $P \subseteq \bar{k}k(P)$, as we may always take $v = 1$.

 Also suppose that $\bar{k}k(P) = P$ and consider some $x \in M$ and $u \in U$, with $ux \in P$. Then $x \in \bar{k}k(P)$ and hence $x \in P$. Conversely suppose, we have $ux \in P \implies x \in P$ for any $x \in M$ and $u \in U$. If now $x \in \bar{k}k(P)$ then $vx \in P$ for some $v \in U$. And by assumption this implies $x \in P$. That is $\bar{k}k(P) \subseteq P$ and as the converse inclusion is generally true this is $\bar{k}k(P) = P$.

- If P and $Q \leq_{\mathsf{m}} M$ are any two R-sub-modules of M, then $P \subseteq Q$ clearly implies $k(P) \subseteq k(Q)$, as stated in the claim. And in order to show $k(P \cap Q) = k(P) \cap k(Q)$ we need to verify the following

equality

$$\left\{ \frac{z}{w} \;\middle|\; \begin{array}{l} w \in U \\ z \in P \cap Q \end{array} \right\} = \left\{ \frac{x}{u} \;\middle|\; \begin{array}{l} u \in U \\ x \in P \end{array} \right\} \cap \left\{ \frac{y}{v} \;\middle|\; \begin{array}{l} v \in U \\ y \in Q \end{array} \right\}$$

The inclusion "$\subseteq$" is trivial, just let $x = z$ and $u = w$ respectively $y = z$ and $v = w$. Conversely suppose we are given some $x/u = y/v$ such that $x \in P$ and $y \in Q$. That is $z := avx = auy$ for some $a \in U$. Yet as P and Q are R-sub-modules, this implies $z \in P \cap Q$. And letting $w := auv$ we hence get $z/w \in k(P \cap Q)$. Now compute $z/w = avx/auv = x/u$ and $z/w = auy/auv = y/v$, from this we see $x/u = y/v = z/w \in k(P \cap Q)$.

- From the definition of $\bar{k}$ it is also clear, that $\bar{k}$ preserves inclusions, as stated in the claim. Also if Z_i (where $i \in I$) is a family of $U^{-1}R$-sub-modules of $U^{-1}M$, then it is clear that

$$\begin{aligned} \bar{k}\left(\bigcap_{i\in I} Z_i\right) &= \left\{ x \in M \;\middle|\; \frac{x}{1} \in \bigcap_{i\in I} Z_i \right\} \\ &= \left\{ x \in M \mid \forall\, i \in I : \frac{x}{1} \in Z_i \right\} \\ &= \bigcap_{i\in I} \left\{ x \in M \mid \frac{x}{1} \in Z_i \right\} = \bigcap_{i\in I} \bar{k}(Z_i) \end{aligned}$$

- At last we have to verify, that for any subset $X \subseteq M$ the sub-module of $U^{-1}M$ generated by $k(X)$ and the image $k(P)$ of the sub-module P of M generated by X are equal. To do this we first take a closer look at the sets involved - by definition we have

$$\begin{aligned} k\Big(\mathrm{Lh}_R(X)\Big) &= \left\{ \frac{1}{w} \sum_{i=1}^{n} a_i x_i \;\middle|\; w \in U, a_i \in R, x_i \in X \right\} \\ \mathrm{Lh}_{U^{-1}R}\Big(k(X)\Big) &= \left\{ \sum_{i=1}^{n} \frac{b_i}{v_i} \frac{x_i}{u_i} \;\middle|\; b_i \in R, u_i, v_i \in U, x_i \in X \right\} \end{aligned}$$

If $x = (1/w)\sum_i a_i x_i = \sum_i (a_i/w)(x_i/1)$ then it is clear that x is contained in the sub-module generated by $k(X)$. Conversely suppose we are given some $x = \sum_i (b_i/v_i)(x_i/u_i)$, then we define $u := u_1 \cdot \ldots u_n$ and $v := v_1 \cdot \cdots \cdot v_n$ also $\widehat{u}_i := u/u_i \in U$ and $\widehat{v}_i := v/v_i \in U$. If we now take to $w := uv$ and $a_i := \widehat{u}_i \widehat{v}_i b_i \in R$, then we can easily compute

$$\frac{1}{w}\sum_{i=1}^{n} a_i x_i = \sum_{i=1}^{n} \frac{a_i x_i}{w} = \sum_{i=1}^{n} \frac{\widehat{u}_i \widehat{v}_i b_i x_i}{uv} = \sum_{i=1}^{n} \frac{b_i x_i}{u_i v_i} \in \mathrm{Lh}_{U^{-1}R}\Big(k(X)\Big)$$

□

Proof of (2.133):

Two of the three implications are clear, thus we are only concerned with: if for any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ we have $a/1 = b/1 \in R_{\mathfrak{m}}$ then already $a = b \in R$. But since $a/1 = b/1$ is equivalent to $(a-b)/1 = 0/1$ it suffices

$$\forall\ \mathfrak{m}\ :\ \frac{a}{1} = \frac{0}{1} \in R_{\mathfrak{m}} \implies a = 0$$

By definition $a/1 = 0/1$ means that there is some $u \notin \mathfrak{m}$ such that $ua = 0$. And the latter can again be

formulated as $u \in \operatorname{ann}(a)$. Thus we have

$$\forall\ \mathfrak{m}\ :\ \operatorname{ann}(a)\ \not\subseteq\ \mathfrak{m}$$

Hence there is no maximal ideal $\mathfrak{m}$ containing $\operatorname{ann}(a)$. But as the annihilator $\operatorname{ann}(a)$ is an ideal this is only possible if $\operatorname{ann}(a) = R$ andchence $a = 1 \cdot a = 0$.
In the second claim it is clear that for any prime ideal $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ we get $R \subseteq R_{\mathfrak{p}} \subseteq F := \operatorname{quot}(R)$. Hence it is clear that $R \subseteq \bigcap_{\mathfrak{p}} R_{\mathfrak{p}}$. And as $\operatorname{Smax}(R) \subseteq \operatorname{Spec}(R)$ it also is clear that $\bigcap_{\mathfrak{p}} R_{\mathfrak{p}} \subseteq \bigcap_{\mathfrak{m}} R_{\mathfrak{m}}$ such that we only have to verify $\bigcap_{\mathfrak{m}} R_{\mathfrak{m}} \subseteq R$. Thus consider any $a/b \in F$ with $a/b \in \bigcap_{\mathfrak{m}} R_{\mathfrak{m}}$. That is for any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} R$ there are some $a(\mathfrak{m}) \in R$ and $b(\mathfrak{m}) \notin \mathfrak{m}$ such that $a/b = a(\mathfrak{m})/b(\mathfrak{m})$. Now define the ideal

$$\mathfrak{b}\ :=\ \langle b(\mathfrak{m}) \mid \mathfrak{m} \in \operatorname{Smax}(R)\rangle_{\mathfrak{i}}\quad \trianglelefteq_{\mathfrak{i}}\quad R$$

Suppose we had $\mathfrak{b} \neq R$, then there would be some maximal ideal $\mathfrak{m}$ such that $\mathfrak{m} \subseteq \mathfrak{m}$. But clearly $b(\mathfrak{m}) \in \mathfrak{b}$ although $b(\mathfrak{m}) \notin \mathfrak{m}$, a contradiction. That is $\mathfrak{b} = R$ and hence $1 \in \mathfrak{b}$. That is there is a finite subset $M \subseteq \operatorname{Smax}(R)$ and there are $r(\mathfrak{m}) \in R$ (where $\mathfrak{m} \in M$) such that $1 = \sum_{\mathfrak{m}} r(\mathfrak{m})b(\mathfrak{m})$. Now recall that $a/b = a(\mathfrak{m})/b(\mathfrak{m})$, then we find $a/b \in R$ by virtue of

$$\frac{a}{b}\ =\ 1 \cdot \frac{a}{b}\ =\ \left(\sum_{\mathfrak{m}\in M} r(\mathfrak{m})b(\mathfrak{m})\right)\frac{a}{b}\ =\ \sum_{\mathfrak{m}\in M} r(\mathfrak{m})a(\mathfrak{m})\ \in\ R$$

□

Proof of (2.119):

- As φ is a homomorphsim of rings, we have $1_S = \varphi(1_R) \in \varphi(U)$. If now $\varphi(u)$, $\varphi(v)$ are any two elements of $\varphi(U)$, then $\varphi(u)\varphi(v) = \varphi(uv) \in \varphi(U)$, since U is a multiplicatively closed set and thereby $uv \in U$ again. Together we see, that $\varphi(U)$ is multiplicatively closed, again.

- To prove that $U^{-1}\varphi$ is well-defined, we start with some $a/u = b/v \in U^{-1}R$. By definition that is $wva = wub$ for some $w \in U$ and hence $\varphi(wva) = \varphi(wub)$. That is $\varphi(w)\varphi(v)\varphi(a) = \varphi(w)\varphi(u)\varphi(b)$ and thereby $\varphi(a)/\varphi(u) = \varphi(b)/\varphi(v)$, as $\varphi(w) \in \varphi(U)$. As these are the images of a/u and b/v respectively, this is the well-definedness of $U^{-1}\varphi$.

- It is straightforward to check, that the map $U^{-1}\varphi$ inherits being a homomorphism of rings from φ. First of all $U^{-1}\varphi(1_R/1_R) = \varphi(1_R)/\varphi(1_R) = 1_S/1_S$. And for any a, $b \in R$ and u, $v \in U$ we compute

$$\begin{aligned}
U^{-1}\varphi\left(\frac{a}{u}\cdot\frac{b}{v}\right) &= U^{-1}\varphi\left(\frac{ab}{uv}\right) = \frac{\varphi(ab)}{\varphi(uv)} = \frac{\varphi(a)\varphi(b)}{\varphi(u)\varphi(v)} = \frac{\varphi(a)}{\varphi(u)}\cdot\frac{\varphi(b)}{\varphi(v)}\\
U^{-1}\varphi\left(\frac{a}{u}+\frac{b}{v}\right) &= U^{-1}\varphi\left(\frac{av+bu}{uv}\right) = \frac{\varphi(av+bu)}{\varphi(uv)}\\
&= \frac{\varphi(a)\varphi(v)+\varphi(b)\varphi(u)}{\varphi(u)\varphi(v)} = \frac{\varphi(a)}{\varphi(u)}+\frac{\varphi(b)}{\varphi(v)}
\end{aligned}$$

- If φ is injective, we just pursue the above arguments in reverse order: If $\varphi(a)/\varphi(u) = \varphi(b)/\varphi(v)$, then $\varphi(w)\varphi(v)\varphi(a) = \varphi(w)\varphi(u)\varphi(b)$ for some $w \in U$. But this is $\varphi(wva) = \varphi(wub)$ and as φ is injective, we conclude $wva = wub$ such that $a/u = b/v$. Thus $U^{-1}\varphi$ is injective again. Now, if φ is

surjective, then for any $s \in S$ there is some $a \in R$, such that $\varphi(a) = s$ and thereby $a/u \mapsto s/\varphi(u)$. Thus $U^{-1}\varphi$ reaches any element of $\varphi(U)^{-1}S$, which means it is surjectve. And as bijective just means "injective and surjective", we also see that $U^{-1}\varphi$ is bijective, whenever φ is.

□

Proof of (2.120):
In the first part we will prove the existence of the induced homomorphism $\overline{\varphi}$. And of course we start with the well-definedness of $\overline{\varphi}$ as a mapping. Thus let us regard $a/u = b/v \in U^{-1}R$. That is there is some $w \in U$ such that $vwa = uwb$. And thereby we get $\varphi(a)\varphi(u)^{-1} = \varphi(b)\varphi(v)^{-1}$ from

$$\varphi(v)\varphi(w)\varphi(a) \;=\; \varphi(vwa) \;=\; \varphi(uwb) \;=\; \varphi(u)\varphi(w)\varphi(b)$$

Next we have to check that $\overline{\varphi}$ truly is a homomorphism of rings. To do this consider any a/u and $b/v \in U^{-1}R$ and compute

$$\begin{aligned}
\overline{\varphi}\left(\frac{a}{u}\cdot\frac{b}{v}\right) &= \overline{\varphi}\left(\frac{ab}{uv}\right) = \varphi(a)\varphi(b)\varphi(u)^{-1}\varphi(v)^{-1} \\
&= \Big(\varphi(a)\varphi(u)^{-1}\Big)\Big(\varphi(b)\varphi(v)^{-1}\Big) = \overline{\varphi}\left(\frac{a}{u}\right)\cdot\overline{\varphi}\left(\frac{b}{v}\right) \\
\overline{\varphi}\left(\frac{a}{u}+\frac{b}{v}\right) &= \overline{\varphi}\left(\frac{av+bu}{uv}\right) = \Big(\varphi(a)\varphi(v)+\varphi(b)\varphi(u)\Big)\varphi(u)^{-1}\varphi(v)^{-1} \\
&= \varphi(a)\varphi(u)^{-1}+\varphi(b)\varphi(v)^{-1} = \overline{\varphi}\left(\frac{a}{u}\right)+\overline{\varphi}\left(\frac{b}{v}\right)
\end{aligned}$$

So we have proved the existence of the homomorphism $\overline{\varphi}$. It remains to verify that this is the unique homomorphism such that $\overline{\varphi}\kappa = \varphi$. That is we consider some homomorphism $\psi : U^{-1}R \to S$ such that for any $a \in R$ we get $\psi(a/1) = \varphi(a)$. Then for any $u \in U \subseteq R$ we get

$$\psi\left(\frac{1}{u}\right) \;=\; \psi\left(\left(\frac{u}{1}\right)^{-1}\right) \;=\; \psi\left(\frac{u}{1}\right)^{-1} \;=\; \varphi(u)^{-1}$$

And thereby we find for any $a/u \in U^{-1}R$ that $\psi(a/u) = \psi(a/1 \cdot 1/u) = \psi(a/1)\psi(1/u) = \varphi(a)\varphi(u)^{-1} = \overline{\varphi}$. That is $\psi = \overline{\varphi}$, that is $\overline{\varphi}$ is unique. □

Proof of (3.132):
As $\alpha : R \to S$ is a ring-homomorphism, it is clear that N can be turned into an R-module, keeping the addition of N and taking to the scalar multiplication $ay := \alpha(a)y$. And as $\alpha(U) \subseteq S^*$ the universal property (2.120) of the localization of rings yields a ring homomorphism $\overline{\alpha} : U^{-1}R \to S$ by letting

$$\overline{\alpha} \;:\; U^{-1}R \to S \;:\; \frac{a}{u} \mapsto \alpha(u)^{-1}\alpha(a)$$

In complete analogy we can turn N into an $U^{-1}R$-module, as well. This time we have to use the scalar multiplication $(a/u)y := \overline{\alpha}(a/u)y = \alpha(u)^{-1}\alpha(a)y$ (and keep the additon of N again).

Next we prove, that $\overline{\varphi}$ truly is a well-defined homomorphism of $U^{-1}R$ modules. Thus consider $x/u = y/v \in U^{-1}M$, that is there is some $w \in U$ such that $wvx = wuy$. In particular (since φ is R-linear) we

get

$$\begin{aligned}\alpha(w)\alpha(u)\varphi(x) &= \alpha(wu)\varphi(x) = wu\varphi(x) = \varphi(wux)\\ &= \varphi(wuy) = wu\varphi(y) = \alpha(wu)\varphi(y) = \alpha(w)\alpha(v)\varphi(y)\end{aligned}$$

And as $\alpha(w) \in S^*$ is invertible, this implies $\alpha(u)\varphi(x) = \alpha(v)\varphi(y)$. Again this is $\overline{\varphi}(x/u) = \alpha(u)^{-1}\varphi(x) = \alpha(v)^{-1}\varphi(y) = \overline{\varphi}(y/v)$. Hence $\overline{\varphi}$ is well-defined and we have to check the homomorphism properties: consider $a/u \in U^{-1}R$ and x/u, $y/v \in U^{-1}M$ again, then we simply compute

$$\begin{aligned}\overline{\varphi}\left(\frac{x}{u}+\frac{y}{v}\right) &= \overline{\varphi}\left(\frac{vx+uy}{uv}\right) = \alpha(uv)^{-1}\varphi(vx+uy)\\ &= \alpha(u)^{-1}\alpha(v)^{-1}\Big(v\varphi(x)+u\varphi(y)\Big)\\ &= \alpha(u)^{-1}\varphi(x)+\alpha(v)^{-1}\varphi(y)\end{aligned}$$

where the latter equality holds true, as $v\varphi(x) = \alpha(v)\varphi(x)$ and $u\varphi(y) = \alpha(u)\varphi(y)$ by definition of the scalar multiplication on N. Likewise

$$\begin{aligned}\overline{\varphi}\left(\frac{a}{u}\frac{y}{v}\right) &= \overline{\varphi}\left(\frac{ay}{uv}\right) = \alpha(uv)^{-1}\varphi(ay)\\ &= \alpha(u)^{-1}\alpha(v)^{-1}\alpha(a)\varphi(y) = \frac{a}{u}\,\overline{\varphi}\left(\frac{y}{v}\right)\end{aligned}$$

It remains to verify the uniqueness of this homomorphism. Hence suppose $\psi : U^{-1}M \to N$ is any homomorphism of R-modules, such that $\varphi = \psi\kappa$. That is $\varphi(x) = \psi(x/1)$ for any $x \in M$. Then for any $u \in U$ we also get $\varphi(x) = \psi(x/1) = \psi(ux/u) = u\psi(x/u) = \alpha(u)\psi(x/u)$. Now, as $\alpha(u) \in S^*$ again we hence get $\psi(x/u) = \alpha(u)^{-1}\varphi(x) = \overline{\varphi}(x/u)$. □

Proof of (2.122):

- By definition $\kappa^{-1}(\mathfrak{u})$ is the set of all $a \in R$ such that $a/1 = \kappa(a) \in \mathfrak{u}$, and this has already been the first claim. And $\kappa^{-1}(\mathfrak{a})$ is an ideal of R by virtue of (1.76.(vii)).

- " $\supseteq$ " If $a \in \mathfrak{a}$ then $a/1 = \kappa(a) \in \kappa(\mathfrak{a}) \subseteq U^{-1}\mathfrak{a}$. And for any $u \in U$ we hence also get $a/u = (1/u)(a/1) \in U^{-1}\mathfrak{a}$. "$\subseteq$" Conversely consider any $x \in \langle\kappa(\mathfrak{a})\rangle_{\mathfrak{i}}$. I.e. there are $a_i \in \mathfrak{a}$ and $x_i = b_i/v_i \in U^{-1}R$ such that

 $$x = \sum_{i=1}^{n} x_i\kappa(a_i) = \sum_{i=1}^{n}\frac{a_ib_i}{v_i}$$

 We now let $v := v_1 \ldots v_n \in U$ and $\widehat{v}_i := v/v_i \in U$ then a straightforward computation shows $x = a/v$ for some $a := \sum_i a_ib_i\widehat{v}_i \in \mathfrak{a}$

 $$x = \sum_{i=1}^{n}\frac{a_ib_i}{v_i} = \sum_{i=1}^{n}\frac{a_ib_i\widehat{v}_i}{v} = \frac{a}{v}$$

□

Proof of (2.124):

- First of all $\mathfrak{a} : U$ is an ideal - $0 \in \mathfrak{a} : U$ since $0 = 1 \cdot 0 \in \mathfrak{a}$. Now consider $a, b \in \mathfrak{a} : U$. That is there are some $u, v \in V$ such that ua and $vb \in \mathfrak{a}$. This yields $uv(a+b) = v(ua) + u(vb) \in \mathfrak{a}$ and hence $a + b \in \mathfrak{a} : U$. Likewise for any $r \in R$ we get $u(ra) = r(ua) \in \mathfrak{a}$ and hence $ra \in \mathfrak{a} : U$.

- Next it is clear that $\mathfrak{a} \subseteq \mathfrak{a} : U$, because if $a \in \mathfrak{a}$ then $a = 1 \cdot a \in \mathfrak{a}$ (due to $1 \in U$) and hence $a \in \mathfrak{a} : U$.

- We finally wish to prove $(U^{-1}\mathfrak{a}) \cap R = \mathfrak{a} : U$. Consider any $b \in \mathfrak{a} : U$, that is $vb \in \mathfrak{a}$ for some $v \in U$. Then $b/1 = vb/v \in U^{-1}\mathfrak{a}$ and hence $b \in (U^{-1}\mathfrak{a}) \cap R$. Conversely let $b \in (U^{-1}\mathfrak{a}) \cap R$, by definition this means $b/1 \in U^{-1}\mathfrak{a}$. That is there is some $a \in \mathfrak{a}$, $u \in U$ such that $b/1 = a/u$. That is there is some $v \in U$ such that $uvb = va \in \mathfrak{a}$. And as $uv \in U$ this means $b \in \mathfrak{a} : U$.

□

Proof of (2.125):

- $U^{-1}(\mathfrak{a} \cap \mathfrak{b}) = (U^{-1}\mathfrak{a}) \cap (U^{-1}\mathfrak{b})$: if $x \in U^{-1}(\mathfrak{a} \cap \mathfrak{b})$ then by definition there are some $a \in \mathfrak{a} \cap \mathfrak{b}$ and $u \in U$ such that $x = a/u$. But as $a \in \mathfrak{a}$ and $a \in \mathfrak{b}$ this already means $x \in U^{-1}\mathfrak{a}$ and $x \in U^{-1}\mathfrak{b}$. If conversely $x = a/u \in U^{-1}\mathfrak{a}$ and $x = b/v \in U^{-1}\mathfrak{b}$ then $a/u = b/v$ means that there is some $w \in U$ such that $vwa = uwb \in \mathfrak{a} \cap \mathfrak{b}$. Hence $x = (vwa)/(uvw) = (uwb)/(uvw) \in U^{-1}(\mathfrak{a} \cap \mathfrak{b})$.

- $U^{-1}(\mathfrak{a} + \mathfrak{b}) = (U^{-1}\mathfrak{a}) + (U^{-1}\mathfrak{b})$: if $x \in U^{-1}(\mathfrak{a} + \mathfrak{b})$ then there are some $a \in \mathfrak{a}$, $b \in \mathfrak{b}$ and $u \in U$ such that $x = (a+b)/u = (a/u) + (b/u) \in (U^{-1}\mathfrak{a}) + (U^{-1}\mathfrak{b})$. And if we are conversely given any $a/u \in U^{-1}\mathfrak{a}$ and $b/v \in U^{-1}\mathfrak{b}$ then $a/u + b/v = (au + bv)/(uv) \in U^{-1}(\mathfrak{a} + \mathfrak{b})$.

- $U^{-1}(\mathfrak{a}\,\mathfrak{b}) = (U^{-1}\mathfrak{a})\,(U^{-1}\mathfrak{b})$: if $x \in U^{-1}(\mathfrak{a}\,\mathfrak{b})$ then there are some $f \in \mathfrak{a}\,\mathfrak{b}$ and $u \in U$ such that $x = f/u$. Again f is of the form $f = \sum_i a_i b_i$ for some $a_i \in \mathfrak{a}$ and $b_i \in \mathfrak{b}$. Altogether we get

$$x \;=\; \frac{f}{u} \;=\; \sum_{i=1}^{n} \frac{a_i b_i}{u} \;=\; \sum_{i=1}^{n} \frac{a_i}{1}\frac{b_i}{u} \;\in\; (U^{-1}\mathfrak{a})\,(U^{-1}\mathfrak{b})$$

 Conversely consider $a_i/u_i \in U^{-1}\mathfrak{a}$ and $b_i/v_i \in U^{-1}\mathfrak{b}$. As always we let $u := u_1 \dots u_n$ and $\widehat{u}_i := u/u_i \in U$ again, likewise $v := v_1 \dots v_n$ and $\widehat{v}_i := v/v_i \in U$. Then $a_i/u_i = (a_i\widehat{u}_i)/u$, $b_i/v_i = (b_i\widehat{v}_i)/v$ and

$$\sum_{i=1}^{n} \frac{a_i}{u_i}\frac{b_i}{v_i} \;=\; \sum_{i=1}^{n} \frac{a_i\widehat{u}_i}{u}\frac{b_i\widehat{v}_i}{v} \;=\; \frac{1}{uv}\sum_{i=1}^{n} \widehat{u}_i a_i \widehat{v}_i a_i b_i \;\in\; U^{-1}\big(\mathfrak{a}\,\mathfrak{b}\big)$$

- $U^{-1}\sqrt{\mathfrak{a}} = \sqrt{U^{-1}\mathfrak{a}}$: if $x \in U^{-1}\sqrt{\mathfrak{a}}$ then $x = b/v$ for some $b \in \sqrt{\mathfrak{a}}$ and $v \in U$. That is there is some $k \in \mathbb{N}$ such that $b^k \in \mathfrak{a}$. And therefore $x^k = b^k/v^k \in U^{-1}\mathfrak{a}$. Hence x is contained in the radical of $U^{-1}\mathfrak{a}$. Conversely consider any $x = b/v$ such that there is some $k \in \mathbb{N}$ with $x^k = b^k/v^k \in U^{-1}\mathfrak{a}$. Then there is some $a \in \mathfrak{a}$ and $u \in U$ such that $b^k/v^k = a/u$. That is $uwb^k = v^k wa \in \mathfrak{a}$ for some $w \in U$. Hence $(uwb)^k = (uw)^{k-1}(uwb^k) \in \mathfrak{a}$, that is $uwb \in \sqrt{\mathfrak{a}}$. And this agian yields $x = b/v = (uwb)/(uvw) \in U^{-1}\sqrt{\mathfrak{a}}$.

- Next we prove $(\mathfrak{a} : U) : U = \mathfrak{a} : U$. Clearly, as $1 \in U$ we have $\mathfrak{a} : U \subseteq (\mathfrak{a} : U) : U$ (as for any $a \in \mathfrak{a} : U$ we have $a = a \cdot 1 \in (\mathfrak{a} : U) : U$). Conversely if $a \in (\mathfrak{a} : U) : U$ then there is some $u \in U$ such that $au \in \mathfrak{a} : U$. Again this means that there is some $v \in U$ such that $a(uv) = (au)v \in \mathfrak{a}$. But as $uv \in U$ this again yields $a \in \mathfrak{a} : U$.

- For $(\mathfrak{a} \cap \mathfrak{b}) : U = (\mathfrak{a} : U) \cap (\mathfrak{b} : U)$ we use a straightforward reasoning again: If $a \in (\mathfrak{a} \cap \mathfrak{b}) : U$ then there is some $u \in U$ such that $au \in \mathfrak{a} \cap \mathfrak{b}$. And this again means $a \in \mathfrak{a} : U$ *and* $a \in \mathfrak{b} : U$. Conversely consider $a \in (\mathfrak{a} : U) \cap (\mathfrak{b} : U)$. That is there are v, $w \in U$ such that $av \in \mathfrak{a}$ and $aw \in \mathfrak{b}$. Now let $u := vw \in U$ then $au = (av)w = (aw)v \in \mathfrak{a} \cap \mathfrak{b}$ such that $a \in (\mathfrak{a} \cap \mathfrak{b}) : U$.

- We turn our attention to $\sqrt{\mathfrak{a} : U} = \sqrt{\mathfrak{a}} : U$. If $\mathfrak{a} : U = R$ then we get $\sqrt{\mathfrak{a} : U} = \sqrt{R} = R$. And as $\mathfrak{a} \subseteq \sqrt{\mathfrak{a}}$ we also have $R = \mathfrak{a} : U \subseteq \sqrt{\mathfrak{a}} : U \subseteq R$. And hence we get $\sqrt{\mathfrak{a} : U} = R = \sqrt{\mathfrak{a}} : U$. Thus assume $\mathfrak{a} : U \neq R$. If $x \in \sqrt{\mathfrak{a} : U}$ then by definition there is some $k \in \mathbb{N}$ such that $x^k \in \mathfrak{a} : U$. And this means $x^k u \in \mathfrak{a}$ for some $u \in U$. Clearly we have $k \geq 1$ as else $u \in \mathfrak{a}$ such that $\mathfrak{a} : U = R$. And thereby we get $(xu)^k = (x^k u)u^{k-1} \in \mathfrak{a}$, too. But this means $xu \in \sqrt{\mathfrak{a}}$ and hence $x \in \sqrt{\mathfrak{a}} : U$. Conversely if $x \in \sqrt{\mathfrak{a}} : U$ then there is some $u \in U$ such that $xu \in \sqrt{\mathfrak{a}}$. Thus there is some $k \in \mathbb{N}$ such that $x^k u^k = (xu)^k \in \mathfrak{a}$. But as $u^k \in U$ this yields $x^k \in \mathfrak{a} : U$ and hence $x \in \sqrt{\mathfrak{a} : U}$.

- $(\mathfrak{u} \cap \mathfrak{w}) \cap R = \kappa^{-1}(\mathfrak{u} \cap \mathfrak{w}) = \kappa^{-1}(\mathfrak{u}) \cap \kappa^{-1}(\mathfrak{w}) = (\mathfrak{u} \cap R) \cap (\mathfrak{w} \cap R) = \mathfrak{a} \cap \mathfrak{b}$.

- $(\mathfrak{u} + \mathfrak{w}) \cap R = (\mathfrak{a} + \mathfrak{b}) : U$: if $c \in (\mathfrak{a} + \mathfrak{b}) : U$ then there are some $a \in \mathfrak{a}$, $b \in \mathfrak{b}$ and $u \in U$ such that $uc = a + b$. That is $(uc)/1 = (a + b)/1 = (a/1) + (b/1) \in \mathfrak{u} + \mathfrak{w}$. And thereby also $c/1 = (1/u)((uc)/1) \in \mathfrak{u} + \mathfrak{w}$. But this finally is $c \in (\mathfrak{u} + \mathfrak{w}) \cap R$. Conversely let $c \in (\mathfrak{u} + \mathfrak{w}) \cap R$, that is $c/1 \in \mathfrak{u} + \mathfrak{w}$. Thereby we find $a/u \in \mathfrak{u}$ and $b/v \in \mathfrak{w}$ such that $c/1 = a/u + b/v = (va + ub)/uv$. Hence there is some $w \in U$ such that $uvwc = vwa + uwb \in \mathfrak{a} + \mathfrak{b}$ (as $a/u \in \mathfrak{u}$ implies $a/1 = (u/1)(a/u) \in \mathfrak{u}$ and hence $a \in \mathfrak{a}$, likewise $b \in \mathfrak{b}$). And as $uvw \in U$ this is $c \in (\mathfrak{a} + \mathfrak{b}) : U$.

- $(\mathfrak{u}\,\mathfrak{w}) \cap R = (\mathfrak{a}\,\mathfrak{b}) : U$: if $c \in (\mathfrak{a}\,\mathfrak{b}) : U$ then there are some $a_i \in \mathfrak{a}$, $b_i \in \mathfrak{b}$ and $u \in U$ such that $uc = \sum_i a_i b_i \in \mathfrak{a}\,\mathfrak{b}$. Thereby $(uc)/1 = \sum_i (a_i/1)(b_i/1) \in \mathfrak{u}\,\mathfrak{w}$ and hence $c/1 = (1/u)((uc)/1) \in \mathfrak{u}\,\mathfrak{w}$ which means $c \in (\mathfrak{u}\,\mathfrak{w}) \cap R$. And if conversely $c \in (\mathfrak{u}\,\mathfrak{w}) \cap R$ then there are $a_i/u_i \in \mathfrak{u}$ and $b_i/v_i \in \mathfrak{w}$ such that
$$\frac{c}{1} \;=\; \sum_{i=1}^{n} \frac{a_i}{u_i}\frac{b_i}{v_i} \;=\; \sum_{i=1}^{n} \frac{a_i b_i \widehat{u}_i \widehat{v}_i}{uv} \;\in\; \mathfrak{u}\,\mathfrak{w}$$
where as usual $u := u_1 \ldots u_n$, $v := v_1 \ldots v_n$ and $\widehat{u}_i := u/u_i$, $\widehat{v}_i := v/v_i \in U$. From this equality we again get $uvwc = \sum_i a_i b_i \widehat{u}_i \widehat{v}_i \in \mathfrak{a}\,\mathfrak{b}$ for some $w \in U$ (as $a_i/u_i \in \mathfrak{u}$ implies $a_i/1 = (u_i/1)(a_i/u_i) \in \mathfrak{u}$ and hence $a_i \in \mathfrak{a}$, likewise $b_i \in \mathfrak{b}$). And as $uvw \in U$ this is $c \in (\mathfrak{a}\,\mathfrak{b}) : U$.

- $\sqrt{\mathfrak{u}} \cap R = \sqrt{\mathfrak{a}}$: if $b \in \sqrt{\mathfrak{u}} \cap R$ then $b/1 \in \sqrt{\mathfrak{u}}$, that is there is some $k \in \mathbb{N}$ such that $(b/1)^k = b^k/1 \in \mathfrak{u}$. Again this is $b^k \in \mathfrak{u} \cap R = \mathfrak{a}$ and hence $b \in \sqrt{\mathfrak{a}}$. Conversely if $b \in \sqrt{\mathfrak{a}}$ then $b^k \in \mathfrak{a}$ for some $k \in \mathbb{N}$. Hence $(b/1)^k = b^k/1 \in \mathfrak{u}$ which yields $b/1 \in \sqrt{\mathfrak{u}}$ and thereby $b \in \sqrt{\mathfrak{u}} \cap R$.

□

Proof of (2.127):

- If x/u is contained in $U^{-1} \bigcap_i \mathfrak{a}_i$ then x is an element of the intersection $x \in \bigcap_i \mathfrak{a}_i$ and hence $x \in \mathfrak{a}_i$ for any $i \in I$. But this means $x/u \in U^{-1}\mathfrak{a}_i$ and as this is true for any $i \in I$, we get $x/u \in \bigcap_i U^{-1}\mathfrak{a}_i$.

- For the converse inclusion we assumed that any $\mathfrak{p}_i \trianglelefteq_{\mathfrak{i}} R$ is a prime ideal satisfying $\mathfrak{p}_i \cap U = \emptyset$. If now $x/u \in \bigcap_i U^{-1}\mathfrak{p}_i$ then for any $i \in I$ there are some $p_i \in \mathfrak{p}_i$ and $u_i \in U$ such that $x/u =$

$p_i/u_i \in U^{-1}\mathfrak{p}_i$. Now fix any $j \in I$ and let $p := p_j$. Regarding any $i \in I$ we then find

$$\frac{p}{u_j} \;=\; \frac{x}{u} \;=\; \frac{p_i}{u_i}$$

That is there is some $v_i \in U$ such that $v_i u_i p = v_i u_j p_i$. As $p_i \in \mathfrak{p}_i$ we have $v_i u_i p \in \mathfrak{p}_i$. But $\mathfrak{p}_i \cap U = \emptyset$ such that $v_i u_i \notin \mathfrak{p}_i$. As $\mathfrak{p}_i$ also is prime, we conclude $p \in \mathfrak{p}_i$. And as this is true for any $i \in I$. Therefore $x/u = p/u_j \in U^{-1}\bigcap_i \mathfrak{p}_i$ such that both sets are equal.

- The second identity is easy: Clearly $x \in \bigcap_i(\mathfrak{u}_i \cap R)$ is equivalent to $x \in \mathfrak{u}_i \cap R$ for any $i \in I$. But this is just $x/1 \in \mathfrak{u}_i$ for any $i \in I$. Hence this again is equivalent to $x/1 \in \bigcap_i \mathfrak{u}_i$ and this again is just another way of saying $x \in (\bigcap_i \mathfrak{u}_i) \cap R$.

□

Proof of (2.128):
Nearly all of the statements are purely definitional. The two exceptions to this are the equalities claimed for $U^{-1}\mathrm{Spec}(R)$ and $U^{-1}\mathrm{Smax}(R)$: Consider any prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{p} \cap U = \emptyset$. If now $ua \in \mathfrak{p}$ then $u \in \mathfrak{p}$ or $a \in \mathfrak{p}$, as $\mathfrak{p}$ is prime. But $u \in \mathfrak{p}$ is absurd, due to $\mathfrak{p} \cap U = \emptyset$. This only leaves $a \in \mathfrak{p}$ and hence $\mathfrak{p} \in U^{-1}\mathrm{Ideal}(R)$. Conversely let $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ be a prime ideal with $\mathfrak{p} = \mathfrak{p} : U$. If now $u \cdot 1 = u \in \mathfrak{p} \cap U$ then $1 \in \mathfrak{p} : U = \mathfrak{p}$ in contradiction to $\mathfrak{p} \neq R$. Hence we get $\mathfrak{p} \cap U = \emptyset$. Now recall that any maximal ideal is prime. Then repeating the arguments above we also find $\mathfrak{m} = \mathfrak{m} : U \iff \mathfrak{m} \cap U = \emptyset$ for any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$. □

Proof of (2.129):

- First of all it is clear that the mapping $\mathfrak{u} \mapsto \mathfrak{u} \cap R = \kappa^{-1}(\mathfrak{u})$ maps ideals to ideals, as it is just the pull back along the homomorphism κ. Now suppose that $ua \in \mathfrak{u} \cap R$ - this is $ua/1 \in \mathfrak{u}$ and hence $a/1 = (1/u)(ua/1) \in \mathfrak{u}$. But this again implies $a \in \mathfrak{u} \cap R$ and hence $\mathfrak{u} \cap R \in U^{-1}\mathrm{Ideal}(R)$. Conversely for any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ the set $U^{-1}\mathfrak{a}$ is an ideal of $U^{-1}R$ by (2.122). Thus both of the mappings are well-defined.

- Next we remark that for any $\mathfrak{a} \in U^{-1}\mathrm{Ideal}(R)$ and $\mathfrak{u} \trianglelefteq_{\mathrm{i}} U^{-1}R$ we obtain

$$(U^{-1}\mathfrak{a}) \cap R \;=\; \mathfrak{a} : U \;=\; \mathfrak{a}$$

$$U^{-1}(\mathfrak{u} \cap R) \;=\; \{\, a/u \mid a/1 \in \mathfrak{u}, u \in U \,\} \;=\; \mathfrak{u}$$

 Thereby the first equality follows from (2.124) and the definition of $U^{-1}\mathrm{Ideal}(R)$. And for the second equality consider a/u where $a/1 \in \mathfrak{u}$. Then we find that $a/u = (1/u)(a/1) \in \mathfrak{u}$ as well. And if conversely $a/u \in \mathfrak{u}$ then we likewise get $a/1 = (u/1)(a/u) \in \mathfrak{u}$ again. Altogether these equalities yield that the maps given are mutually inverse.

- If $\mathfrak{a} \subseteq \mathfrak{b}$ and we consider any $a/u \in U^{-1}\mathfrak{a}$ then $a \in \mathfrak{a} \subseteq \mathfrak{b}$ and hence $a/u \in U^{-1}\mathfrak{b}$. And if conversely $\mathfrak{u} \subseteq \mathfrak{w}$ and $a \in \mathfrak{u} \cap R$ then $a/1 \in \mathfrak{u} \subseteq \mathfrak{w}$ such that $a \in \mathfrak{w} \cap R$. That is both of the mappings are order preserving.

- Next we want to prove that this correspondence preserves radical ideals. Thus if $\mathfrak{a} \in U^{-1}\mathrm{Ideal}(R)$ is a radical ideal then we have $\mathfrak{a} = \sqrt{\mathfrak{a}}$ and thereby $U^{-1}\mathfrak{a}$ is a radical ideal due to (2.125) (see

below). Likewise we see that if $\mathfrak{u} \in \mathrm{Ideal}(U^{-1}R)$ is a radical ideal, then $\mathfrak{u} \cap R$ is radical, too:

$$\sqrt{U^{-1}\mathfrak{a}} \;=\; U^{-1}\big(\sqrt{\mathfrak{a}}\big) \;=\; U^{-1}\mathfrak{a}$$

$$\sqrt{\mathfrak{u} \cap R} \;=\; \sqrt{\mathfrak{u}} \cap R \;=\; \mathfrak{u} \cap R$$

- Thus it only remains to verify that prime (resp. maximal) ideals are truly correspond to prime (resp. maximal) ideals. For prime ideals this is an easy, straightforward computation: $ab/uv \in U^{-1}\mathfrak{p}$ implies $ab \in \mathfrak{p}$ thus $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$ which again is $a/u \in U^{-1}\mathfrak{p}$ or $b/v \in U^{-1}\mathfrak{p}$. Conversely $ab \in \mathfrak{r} \cap R$ implies $ab/1 \in \mathfrak{r}$ and hence $a/1 \in \mathfrak{r} \cap R$ or $b/1 \in \mathfrak{r} \cap R$. And for maximal ideals this is clear, as the mappings given obviously preserve inclusions.

□

Proof of (2.132):

(i) Consider any two polynomials $f, g \in R[t \mid A]$ and $u, v \in U$. Let us first evaluate what property (a) $f/u = g/v$ means explicitly: By definition of the localisation, this is $wvf = wug$ for some $w \in U$. And if we write out f and g as linear combinations over the monomials t^α this turns into

$$\begin{aligned}
\frac{f}{u} = \frac{g}{v} \quad &\Longleftrightarrow \quad \exists\, w \in U \,:\, wv \sum_{\alpha\in A} f[\alpha]t^\alpha \;=\; wu \sum_{\alpha\in A} g[\alpha]t^\alpha \\
&\Longleftrightarrow \quad \exists\, w \in U \,:\, \sum_{\alpha\in A} \big(wvf[\alpha] - wug[\alpha]\big)t^\alpha \;=\; 0 \\
&\Longleftrightarrow \quad \exists\, w \in U \,:\, \forall\, \alpha \in A \,:\, wvf[\alpha] \;=\; wug[\alpha]
\end{aligned}$$

On the other hand let us evaluate let us evaluate property (b) that the images of f/u and g/v are identical. Clearly that is $f[\alpha]/u = g[\alpha]/v$ for any $\alpha \in A$ and hence we find

$$\sum_{\alpha\in A} \frac{f[\alpha]}{u} t^\alpha \;=\; \sum_{\alpha\in A} \frac{g[\alpha]}{v} t^\alpha \quad\Longleftrightarrow\quad \forall\, \alpha \in A \,:\, \exists\, w(\alpha) \in U \,:\, w(\alpha)vf[\alpha] \;=\; w(\alpha)ug[\alpha]$$

In the direction (a) $\Longrightarrow$ (b) we may take $w(\alpha) := w$ and thus the map $f/u \mapsto \sum_\alpha f[\alpha]/u\, t^\alpha$ is well-defined. For (b) $\Longrightarrow$ (a) we use that $A_f := \{\, \alpha \in A \mid f[\alpha] \neq 0 \,\}$ is a finite set and the same is true for $A_g \subseteq A$. That is for any $\alpha \notin A_f \cup A_g$ we have $f[\alpha] = g[\alpha] = 0$. For such an α we may take $w(\alpha) = 1$ in this case. Therefore the following product in R in truth runs over the finite subset $A_f \cup A_g \subseteq A$ only and hence returns a well-defined element of U

$$w \;:=\; \prod_{\alpha\in A} w(\alpha) \;\in\; U$$

If we take $\widehat{w}(\alpha) := w/w(\alpha) \in U$, as usual we get $\widehat{w}(\alpha) \cdot w(\alpha) = w$ for any $\alpha \in A$. So multiplying the identity $w(\alpha)vf[\alpha] = w(\alpha)ug[\alpha]$ with $\widehat{w}(\alpha)$ we get $wvf[\alpha] = wug[\alpha]$ for any $\alpha \in A$. And as this w is identical for any $\alpha \in A$, we see (b) $\Longrightarrow$ (a), as well. This is the injectivity of the map $f/u \mapsto \sum_\alpha f[\alpha]/u\, t^\alpha$. And as this map is defined by linear expansion of $t^\alpha \mapsto 1/ut^\alpha$ it is clear, that it is R-linear again. It also is a homomorphism of rings, as the multiplications on the polynomial rings $R[t \mid A]$ and $U^{-1}R[t \mid A]$ have bee defined in precisely the same way.

So it only remains to verify the surjectivity: That is we are given any polynomial $p \in U^{-1}R[t \mid A]$

and need to find some $f \in R[t \mid A]$ and $u \in U$ such that $f/u \mapsto p$. By definition any coefficient of p is if the form $p[\alpha] = a[\alpha]/u[\alpha]$ for some $a[\alpha] \in R$ and $u[\alpha] \in U$. Again $A_p = \{\, \alpha \in A \mid p[\alpha] \neq 0 \,\}$ is finite and for $\alpha \notin A_p$ we may take $u[\alpha] = 1$, as $0/u = 0/1$ for any $u \in U$. Therefore the following product is a well-defined element of U again, as in truth it runs over A_p only

$$u \;:=\; \prod_{\alpha \in A} u[\alpha] \;\in\; U$$

As before, let $\widehat{u}[\alpha] := u/u[\alpha] \in U$ such that $\widehat{u}[\alpha] \cdot u[\alpha] = u$. Also let $f[\alpha] := \widehat{u}[\alpha]a[\alpha] \in R$, then it is easy to compute, that we have the following identity

$$p[\alpha] \;=\; \frac{a[\alpha]}{u[\alpha]} \;=\; \frac{a[\alpha]\widehat{u}[\alpha]}{u[\alpha]\widehat{u}[\alpha]} \;=\; \frac{f[\alpha]}{u}$$

Now define $f := \sum_\alpha f[\alpha]t^\alpha$ and note that $A_f = \{\, \alpha \in A \mid f[\alpha] \,\} \subseteq A_p$ is finite (such that f truly is a polynomial in $R[t \mid A]$), then it becomes apparent, that

$$\frac{f}{u} \;\mapsto\; \sum_{\alpha \in A} \frac{f[\alpha]}{u} t^\alpha \;=\; \sum_{\alpha \in A} p[\alpha]\, t^\alpha \;=\; p$$

(ii) Let us regard the map $b/v \mapsto (b+\mathfrak{a})/(v+\mathfrak{a})$. We first check its well-definedness: Suppose $a/u = b/v \in U^{-1}R$, that is there is some $w \in U$ such that $vwa = uwb$. Of course this yields $(v+\mathfrak{a})(w+\mathfrak{a})(a+\mathfrak{a}) = (u+\mathfrak{a})(w+\mathfrak{a})(b+\mathfrak{a})$. But as $w \in U$ we also have $w+\mathfrak{a} \in U/\mathfrak{a}$ and hence $(a+\mathfrak{a})/(u+\mathfrak{a}) = (b+\mathfrak{a})/(v+\mathfrak{a})$. And it is immediately clear that this map even is a homomorphism of rings. Next we will prove its surjectivity, that is we are given any $(b+\mathfrak{a})/(v+\mathfrak{a}) \in (U/\mathfrak{a})^{-1}(R/\mathfrak{a})$. As $v+\mathfrak{a} \in U/\mathfrak{a}$ there is some $u \in U$ such that $v+\mathfrak{a} = u+\mathfrak{a}$. But from this we find $b/u \in U^{-1}R$ and $b/u \mapsto (b+\mathfrak{a})/(u+\mathfrak{a}) = (b+\mathfrak{a})/(v+\mathfrak{a})$. Thus it remains to prove

$$\mathrm{kn}\left(\frac{b}{v} \mapsto \frac{b+\mathfrak{a}}{v+\mathfrak{a}}\right) \;=\; U^{-1}\mathfrak{a} \;=\; \left\{ \frac{a}{u} \;\middle|\; a \in \mathfrak{a}, u \in U \right\}$$

The inclusion " $\supseteq$ " is clear, given a/u where $a \in \mathfrak{a}$ we immediately find that $(a+\mathfrak{a})/(u+\mathfrak{a}) = (0 \cdot u + \mathfrak{a})/(1 \cdot u + \mathfrak{a}) = (0+\mathfrak{a})/(1+\mathfrak{a}) = 0$. Conversely consider some $b/v \in U^{-1}R$ such that $(b+\mathfrak{a})/(v+\mathfrak{a}) = 0 = (0+\mathfrak{a})/(1+\mathfrak{a})$. That is there is some $x+\mathfrak{a} \in U/\mathfrak{a}$ such that $xb+\mathfrak{a} = (x+\mathfrak{a})(b+\mathfrak{a}) = 0+\mathfrak{a}$. And this means $xb \in \mathfrak{a}$. Further - since $x+\mathfrak{a} \in U/\mathfrak{a}$ - there is some $w \in U$ such that $x+\mathfrak{a} = w+\mathfrak{a}$. That is $a := w - x \in \mathfrak{a}$. Now compute $bw = bw - bx + bx = ba + bx \in \mathfrak{a}$. Hence we found $b/v = (bw)/(vw) \in U^{-1}\mathfrak{a}$. Thus according to the isomorphism theorem $b/v \mapsto (b+\mathfrak{a})/(v+\mathfrak{a})$ induces the isomorphy as given in the claim.

(iii) We regard the homomorphism $R[t] \mapsto R_u : f \mapsto f(1/u)$. It is clear that this is surjective, since $at^k \mapsto a/u^k$ reaches all the elements of R_u. We will now show that the kernel is given to be

$$\mathrm{kn}(f \mapsto f(1/u)) \;=\; (ut-1)R[t]$$

The inclusion " $\supseteq$ " is clear, as $ut-1 \mapsto u/u - 1/1 = 0/1$. Thus suppose $f \mapsto 0/1$, then we need to show that $ut-1 \mid f$ in $R[t]$. Let $f/1 := \kappa(f) \in (U^{-1}R)[t]$ then it is clear that $1/u$ is a root

$(f/1)(1/u) = f(1/u) = 0/1$ of $f/1$ and hence $t - 1/u \mid f/1$ in $(U^{-1}R)[t]$. Since $u/1$ is a unit in R_u multiplication with $u/1$ changes nothing and hence $(ut-1)/1 \mid f/1 \in (U^{-1}R)[t]$. Thus

$$\frac{f}{1}(U^{-1}R)[t] \quad \subseteq \quad \frac{ut-1}{1}(U^{-1}R)[t]$$

But it is clear that the ideal $f/1(U^{-1}R)[t]$ corresponds to $fR[t]$ formally $(f/1(U^{-1}R)[t]) \cap R[t] = fR[t]$. And likewise the other ideal $(ut-1)/1f/1(U^{-1}R)[t]$ corresponds to $(ut-1)R[t]$. As the correspondence respects inclusions we have finally found

$$fR[t] \quad \subseteq \quad (ut-1)R[t]$$

This means $f \in (ut-1)R[t]$ and hence we have also proved "$\subseteq$". Thus $f \mapsto f(1/u)$ induces the isomorphism given its inverse is obviously given by $a/u^k \mapsto at^k + (ut-1)R[t]$.

(iv) First of all $U^{-1}R$ is an integral domain by (2.131) and hence the quotient field $\mathrm{quot}(U^{-1}R)$ is well-defined again. We will now prove the well-definedness and injectivity of the map $a/b \mapsto (a/1)/(b/1)$. As R is an integral domain (and $0 \notin U$) we get (for any a, b, c and $d \in R$)

$$\begin{aligned}
\frac{a/1}{b/1} = \frac{c/1}{d/1} \quad &\iff \quad \frac{ad}{1} = \frac{a}{1}\cdot\frac{d}{1} = \frac{b}{1}\cdot\frac{c}{1} = \frac{bc}{1} \\
&\iff \quad \exists\, u \in U \;:\; uad = ubv \\
&\iff \quad ad = bc \\
&\iff \quad \frac{a}{b} = \frac{c}{d}
\end{aligned}$$

The homomorphism property of $a/b \mapsto (a/1)/(b/1)$ is clear by definition of the addition and multiplication in localizations. Thus it only remains to check the surjectivity: consider any $(a/u)/(b/v) \in \mathrm{quot}(U^{-1}R)$, then we claim $av/bu \mapsto (a/u)/(b/v)$. To see this we have to show $(av/1)/(bu/1) = (a/u)/(b/v)$ and this follows from:

$$\frac{a}{u}\frac{bu}{1} \;=\; \frac{abu}{u} \;=\; \frac{ab}{1} \;=\; \frac{abv}{v} \;=\; \frac{b}{v}\frac{av}{1}$$

(v) We first check the well-definedness and injectivity of the map given. This can be done simultaneously by the following computation (recall that R is an integral domain and a, $b \neq 0$)

$$\begin{aligned}
\frac{x/a^h}{(b/a^n)^i} = \frac{y/a^j}{(b/a^n)^k} \quad &\iff \quad \left(\frac{b}{a^n}\right)^k \frac{x}{a^h} = \left(\frac{b}{a^n}\right)^i \frac{x}{a^j} \\
&\iff \quad \frac{xb^k}{a^{kn+h}} = \frac{yb^i}{a^{in+j}} \\
&\iff \quad xa^{in+j}b^k = ya^{kn+h}b^i \\
&\iff \quad a^{i+k}b^{h+j}\left(xa^{in+j}b^k - ya^{kn+h}b^i\right) = 0 \\
&\iff \quad xa^{in+i+j+k}b^{h+j+k} = ya^{kn+h+i+k}b^{h+i+j} \\
&\iff \quad (ab)^{j+k}xa^{(n+1)i}b^h = (ab)^{h+i}ya^{(n+1)k}b^j \\
&\iff \quad \frac{xa^{(n+1)i}b^h}{(ab)^{h+i}} = \frac{ya^{(n+1)k}b^j}{(ab)^{j+k}}
\end{aligned}$$

Hence we have a well-defined injective mapping and it is straightforward to check that it even is a homomorphism of rings. Thus it only remains to check the surjectivity. That is we are given any $x/(ab)^k \in R_{ab}$, then we obtain a preimage by

$$\frac{x/a^{(n+1)k}}{(b/a^n)^k} \;\mapsto\; \frac{xa^{(n+1)k}b^{(n+1)k}}{(ab)^{n+1)k+k}} \;=\; \frac{x}{(ab)^k}$$

(vi) Let us denote $U := R \setminus \mathfrak{p}$, as $\mathfrak{a} \subseteq \mathfrak{p}$ we get $U \cap \mathfrak{a} = \emptyset$ and $\mathfrak{a}_\mathfrak{p} = U^{-1}\mathfrak{a}$ is just the definition. Hence the claim is already included in (v).

(vii) We first show that this mapping is well defined, i.e. $u/1 \notin \overline{p}$ for $u \notin \mathfrak{p}$. But this is clear, since $\mathfrak{p} = \overline{p} \cap R$. Thus we concern ourselves with the surjectivety: given $(r/a^k)/(u/a^l) \in (R_a)_{\overline{\mathfrak{p}}}$ we see that

$$\frac{ra^l}{ua^k} \;\mapsto\; \frac{ra^l/1}{ua^k/1} \;=\; \frac{1/a^{k+l}}{1/a^{k+l}} \cdot \frac{ra^l/1}{ua^k/1} \;=\; \frac{r/a^k}{u/a^l}$$

And for the injectivety we have to consider $(r/1)/(u/1) = (s/1)/(v/1)$. Hence there is some $w/a^m \notin \overline{\mathfrak{p}}$ such that $vwr/a^m = uws/a^m \in R_a$. Thus there is some $n \in \mathbb{N}$ such that $a^{m+n}vwr = a^{m+n}uws \in R$. But $w/a^m \notin \overline{\mathfrak{p}}$ means that $w \notin \mathfrak{p}$ and as also $a \notin \mathfrak{p}$ we get that $z := a^{m+n}w \notin \mathfrak{p}$. But as $vrz = usz$ this means that $r/u = s/v \in R_\mathfrak{p}$.

□

Proof of (2.131):

- R integral domain $\implies$ $U^{-1}R$ integral domain
 Suppose $(ab)/(uv) = (a/u)(b/v) = 0/1 \in U^{-1}R$. By definition of the localization this means that there is some $w \in U$ such that $wab = 0$. But $w \neq 0$ (as $0 \notin U$) and R is an itegral domain, thus we get $ab = 0$. And this again yields $a = 0$ or $b = 0$. Of course this yields $a/u = 0/1$ or $b/v = 0/1$, that is $U^{-1}R$ is an itegral domain.

- R noetherian/artinian $\implies$ $U^{-1}R$ noetherian/artinian
 Suppose that R is noetherian and consider an ascending chain of ideals $\mathfrak{u}_1 \subseteq \mathfrak{u}_2 \subseteq \mathfrak{u}_3 \subseteq \ldots$ in $U^{-1}R$. Let us denote the corresponding ideals of R by $\mathfrak{a}_k := \mathfrak{u}_k \cap R$. Then the $\mathfrak{a}_k$ form an ascending chain $\mathfrak{a}_1 \subseteq \mathfrak{a}_2 \subseteq \mathfrak{a}_3 \subseteq \ldots$ of idelas of R, too. And as R is noetherian this means that there is some $s \in \mathbb{N}$ such that the chain stabilizes

 $$\mathfrak{a}_1 \;\subseteq\; \mathfrak{a}_2 \;\subseteq\; \mathfrak{a}_3 \;\subseteq\; \ldots \;\subseteq\; \mathfrak{a}_s \;=\; \mathfrak{a}_{s+1} \;=\; \mathfrak{a}_{s+2} \;=\; \ldots$$

 Yet the ideals correspond to one and another, that is $\mathfrak{u}_k = U^{-1}\mathfrak{a}_k$. So if we transfer this stabilized chain back to $U^{-1}R$ we find that

 $$\mathfrak{u}_1 \;\subseteq\; \mathfrak{u}_2 \;\subseteq\; \mathfrak{u}_3 \;\subseteq\; \ldots \;\subseteq\; \mathfrak{u}_s \;=\; \mathfrak{u}_{s+1} \;=\; \mathfrak{u}_{s+2} \;=\; \ldots$$

 the corresponding chain stabilized, too. And as the chain has been arbitrary this means, that $U^{-1}R$ is noetherian, as well. The fact that R artinian implies $U^{-1}R$ artinian can be proved in complete analogy.

- R PID $\implies$ $U^{-1}R$ PID
 Consider any ideal $\mathfrak{u} \trianglelefteq_{\mathrm{i}} U^{-1}R$, by the correspondence theorem (2.129) $\mathfrak{u}$ corresponds to the ideal $\mathfrak{a} := \mathcal{U} \cap R \trianglelefteq_{\mathrm{i}} R$ of R. But as R is a PID there is some $a \in R$ such that $\mathfrak{a} = aR$. And the following computation yields that $\mathfrak{u} = (a/1)U^{-1}R$ is a principal ideal, too

$$\mathfrak{u} \;=\; U^{-1}(aR) \;=\; \left\{ \frac{ab}{u} \;\middle|\; b \in R, u \in U \right\} \;=\; \frac{a}{1}U^{-1}R$$

- R UFD $\implies$ $U^{-1}R$ UFD
 If $0 \in U$ then $U^{-1}R = 0$ and hence $U^{-1}R$ is a UFD. Thus suppose $0 \notin U$. By definition any UFD R is an integral domain, and hence $U^{-1}R$ is an integral domain, too. Thus it suffices to check that any $a/u \in U^{-1}R$ admits a decomposition into prime factors. To see this we will first prove the following assertion

$$p \in R \text{ prime} \quad\Longrightarrow\quad \frac{p}{1} \in \left(U^{-1}R\right)^* \text{ or } \frac{p}{1} \in \left(U^{-1}R\right) \text{ prime}$$

 Thus let $p \in R$ be prime and assume $p/1 \mid (a/u)(b/v) = (ab)/(uv)$. That is there is some $h/w \in U^{-1}R$ such that $ph/w = ab/uv$. And as R is an integral domain this implies $uvph = wab$. In particular $p \mid wab$ and as p is prime this means $p \mid w$ or $p \mid a$ or $p \mid b$. First suppose $p \mid w$, i.e. there is some $\gamma \in R$ such that $\gamma p = w$. Then $(p/1)(\gamma/w) = w/w = 1$ and hence $p/1 \in (U^{-1}R)^*$ is a unit. Otherwise, if $p \mid a$ - say $\alpha p = a$ - then $(p/1)(\alpha/u) = a/u$. That is $p/1 \mid a/u$. Analogously we find $p \mid b \implies p/1 \mid b/v$. Thus either $p/1$ is a unit or prime, as claimed. Now we may easily verify that $U^{-1}R$ is an UFD: consider any $0 \neq a/u \in U^{-1}R$. As R is an UFD we find a decomposition of $a \neq 0$ into prime elements $a = \alpha p_1 \dots p_k$ (where $\alpha \in R^*$ and $p_i \in R$ prime). Now let $I := \left\{ i \in I \mid p_i/1 \in (U^{-1}R)^* \right\}$ be the set of indexes i for which $p_i/1$ is a unit. Then

$$\frac{a}{u} \;=\; \frac{\alpha}{u}\frac{p_1}{1}\cdots\frac{p_k}{1} \;=\; \left(\frac{\alpha}{u}\prod_{i\in I}\frac{p_i}{1}\right)\prod_{i\notin I}\frac{p_i}{1}$$

 That is we have found a decomposition of a/u into (a unit and) prime factors. And as a/u has been an arbitrary non-zero element, this proves that $U^{-1}R$ truly is an UFD.

- R normal $\implies$ $U^{-1}R$ normal
 We have already seen that $U^{-1}R$ is an integral domain, since R is an integral domain. To prove that $U^{-1}R$ is integrally closed in its quotient field we will make use of the isomorphy (2.132.(iii))

$$\Phi \;:\; \mathrm{QUOT}(R) \;\xrightarrow{\sim}\; \mathrm{QUOT}(U^{-1}R) \;:\; \frac{r}{s} \mapsto \frac{r/1}{s/1}$$

 Recall that R is embedded canonically into $\mathrm{QUOT}(R)$ by $a \mapsto a/1$. Hence $\mathrm{QUOT}(R)$ is considered to be an R-algebra under the scalar multiplication $a(r/s) := (a/1)\cdot(r/s) = ar/s$. Analogously, for any $a/w \in U^{-1}R$ and any r/u, $s/v \in U^{-1}R$ we have

$$\frac{a}{w}\frac{r/u}{s/v} \;=\; \frac{a/w}{1/1}\cdot\frac{r/u}{s/v} \;=\; \frac{ar/uw}{s/v}$$

 Thus if we consider any $a \in R$ and any $r/s \in \mathrm{QUOT}(R)$, then the isomorphism φ satisfies $\Phi(ax) =$

$(a/1)\Phi(x)$, which can be seen in a straightforward computation

$$\begin{aligned}\Phi(ax) &= \Phi\left(\frac{ar}{s}\right) = \frac{ar/1}{s/1} = \frac{a/1}{1/1}\cdot\frac{r/1}{s/1}\\ &= \frac{a}{1}\frac{r/1}{s/1} = \frac{a}{1}\Phi\left(\frac{r}{s}\right) = \frac{a}{1}\Phi(x)\end{aligned}$$

Now consider any $x/y \in \mathrm{quot}(U^{-1}R)$, that is integral over $U^{-1}R$. That is there are some $n \in \mathbb{N}$ and $p_0, \ldots, p_{n-1} \in U^{-1}R$ such that

$$\left(\frac{x}{y}\right)^n + \sum_{k=0}^{n-1} p_k \left(\frac{x}{y}\right)^k = 0$$

Then we need to show that $x/y \in U^{-1}R$. To do this let us pick up some $r/s \in \mathrm{quot}(R)$ such that $x/y = \Phi(r/s)$. Further note that $p_k \in U^{-1}R$, that is $p_k = a_k/u_k$ for some $a_k \in R$ and $u_k \in U$ and let $u := u_0 \ldots u_{n-1} \in U$. Then multiplication with $u^n/1 \in U^{-1}R$ yields

$$\left(\frac{u}{1}\Phi\left(\frac{r}{s}\right)\right)^n + \sum_{k=0}^{n-1} \frac{a_k u^{n-k}}{u_k}\left(\frac{u}{1}\Phi\left(\frac{r}{s}\right)\right)^k = 0$$

Now recall that $(u/1)\Phi(r/s) = \Phi(u(r/s)) = \Phi(ur/s)$. Further note that due to $k < n$ we have $u_k \mid u \mid u^{n-k}$. Therefore we may define $b_k := a_k u^{n-k}/u_k \in R$. Inserting this in the above equation yields

$$\Phi\left(\frac{ur}{s}\right)^n + \sum_{k=0}^{n-1} \frac{b_k}{1}\Phi\left(\frac{ur}{s}\right)^k = 0$$

Again we use $(b_k/1)\Phi(ur/s) = \Phi(b_k(ur/s))$ and use the homomorphism properties of Φ to place Φ in front, obtaining an equation of the form $\Phi(\ldots) = 0$. But as Φ has been an isomorphism it can be eliminated from this equation ultimatly yielding

$$\left(\frac{ur}{s}\right)^n + \sum_{k=0}^{n-1} b_k\left(\frac{ur}{s}\right)^k = 0$$

Thus we have found that $ur/s \in \mathrm{quot}(R)$ is integral over R. Hence by assumption on R we have $ur/s \in R$, that is there is some $a \in R$ such that $ur/s = a/1$. And this is $ur = as$ such that $r/s = a/u \in U^{-1}R$. Thus we have finally found

$$\frac{x}{y} = \Phi\left(\frac{r}{s}\right) = \Phi\left(\frac{a}{u}\right) = \frac{a/1}{u/1} = \frac{a/u}{1/1} \in U^{-1}R$$

- R Dedekind domain $\implies$ $U^{-1}R$ Dedekind domain
 If R is a Dedekind domain, then R is noetherian, integrally closed and $\mathrm{Spec}(R) = \{0\} \cup \mathrm{Smax}(R)$. As we have seen this implies, that $U^{-1}R$ is noetherian and integrally closed, too. Thus consider a non-zero prime ideal $0 \neq \mathfrak{w} \trianglelefteq_{\mathrm{i}} U^{-1}R$. Then $\mathfrak{m} := \mathfrak{w} \cap R \trianglelefteq_{\mathrm{i}} R$ is a non-zero prime ideal of R, too (if we had $\mathfrak{m} = 0$ then $\mathfrak{w} = U^{-1}\mathfrak{m} = 0$, a contradiction). Thus $\mathfrak{m}$ is maximal and hence $\mathfrak{w} = \mathfrak{m}R$ is maximal, too. That is $\mathrm{Spec}(U^{-1}R) = \{0\} \cup \mathrm{Smax}(U^{-1}R)$. Altogether $U^{-1}R$ is a Dedekind domain, too.

□

Proof of (3.131):

- Let us first verify (i): consider any $x/u \in U^{-1}M$, as M is generated by $\{ m_i \mid i \in I \}$ there is a finite subset $\Omega \subseteq I$ and some $a_i \in R$ such that $x = \sum_i a_i m_i$. And these can easily be used to write x/u in the following form

$$\frac{x}{u} \;=\; \sum_{i\in\Omega} \frac{a_i}{u}\frac{m_i}{1} \;\in\; \mathsf{Lh}_{U^{-1}R}\left(\left\{ \frac{m_i}{1} \;\middle|\; i \in I \right\}\right)$$

 In particular if M is a finitely generated R module, then I can be chosen to be finite itself and hence $U^{-1}M$ is a finitely generated $U^{-1}R$-module again.

- Next we will prove property (ii): that is we need to show that the subset $\{ m_i/1 \mid i \in I \}$ is linearly independent again. To do this suppose we had a finite subset $\Omega \subseteq I$ and some $a_i/u_i \in U^{-1}R$ such that

$$\frac{0}{1} \;=\; \sum_{i\in\Omega} \frac{a_i}{u}\frac{m_i}{1} \;=\; \frac{\sum_{i\in\Omega} a_i\widehat{u}_i m_i}{u}$$

 where as usual we let $u := \prod_i u_i$ (where the product runs over $i \in \Omega$) and $\widehat{u}_i := u/u_i \in U$. That is there is some $w \in U$ such that

$$0 \;=\; w\sum_{i\in\Omega} a_i\widehat{u}_i m_i \;=\; \sum_{i\in\Omega} w\widehat{u}_i a_i m_i$$

 However, as $\{ m_i \mid i \in I \}$ is R-linearly independent this implies $w\widehat{u}_i a_i = 0$ for any $i \in \Omega$. And as $w\widehat{u}_i \in U$ we obtain $a_i/u_i = 0/1$ in $U^{-1}R$ from this equality. Altogether we have proved that $\{ m_i/1 \mid i \in I \}$ truly is $U^{-1}R$-linearly independent.

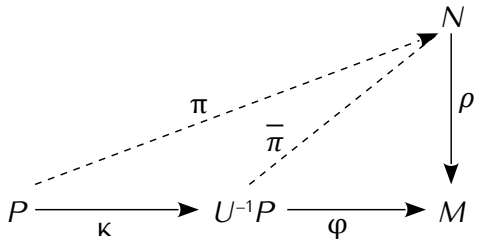
- Combining (i) and (ii) we gain (iii): if $\{ m_i \mid i \in I \}$ is an R-basis of M, then $\{ m_i/1 \mid i \in I \}$ is an $U^{-1}R$ basis of $U^{-1}M$. In particular if M is free (it admits a basis) then $U^{-1}M$ is free as well (it also admits a basis). In fact this even shows the equality of the dimension

$$\dim(U^{-1}M) \;=\; \dim(M)$$

- Let us now prove that $U^{-1}M$ is noetherian again, supposed M is noetherian. I.e. we regard an ascending chain of sub-modules of $U^{-1}M$

$$Z_0 \;\subseteq\; Z_1 \;\subseteq\; \ldots \subseteq\; Z_k \;\subseteq\; Z_{k+1} \;\subseteq\; \ldots$$

 Let us denote $P_k := \overline{k}(Z_k) \;\leq_{\mathsf{m}}\; M$ then - as $\overline{k}$ respects the inclusion relation - this gives rise to an ascending chain of sub-modules of M



$$P_0 \;\subseteq\; P_1 \;\subseteq\; \ldots \subseteq\; P_k \;\subseteq\; P_{k+1} \;\subseteq\; \ldots$$

 Refer to (3.127) for the definition and properties of the map $\overline{k}$. But by assumption M is noetherian and hence this chain has to stabilize, that is there is some $s \in \mathbb{N}$ such that for any $i \in \mathbb{N}$ we get $P_{s+i} = P_s$. Then we get $k(P_{s+i}) = k(P_s)$ as well. But as k is the left-iverse $k\overline{k} = \mathbb{1}$ of $\overline{k}$ this

already implies $Z_{s+i} = k(P_{s+i}) = k(P_s) = Z_s$ which means that the chain of the Z_k had to stabilize. Altogether this is the noetherian property of $U^{-1}M$ again.

- From the above arguments it is clear that $U^{-1}M$ is artinian again, supposed M is artinian. All we have to do is reverse the order of inclusions, i.e. take to a descending chain instead of an ascending chain of sub-modules of $U^{-1}M$.

- Suppose P is a projective R-module, then we would like to verify that $U^{-1}P$ is a projective $U^{-1}R$-module. That is we are given another two $U^{-1}R$-modules M and N, a surjective $U^{-1}R$-module homomorphism $\varrho : N \twoheadrightarrow M$ and an arbitrary $U^{-1}R$-module homomorphism $\varphi : U^{-1}P \to M$. The projective property demands the existence (but not the uniqueness) of another $U^{-1}R$-module homomorphism $\overline{\pi} : U^{-1}P \to N$, such that $\varphi = \varrho\overline{\pi}$. But as P is projective by assumption we may expand this diagram, and use the projective property of P:

That is we pick up the R-module homomorphism $\pi : P \to N$ such that $\varphi\kappa = \varrho\pi$. Then we take $\overline{\pi} : U^{-1}P \to N : x/u \mapsto (1/u)\pi(x)$, that is $\overline{\pi}$ is $U^{-1}\pi$ appended, by $y/u \mapsto (1/u)y$. Hence it is clear that $\overline{\pi}$ is a well-defined $U^{-1}R$-module homomorphism again, due to (3.125.(ii)). We now need to verify $\varphi = \varrho\overline{\pi}$. But this can be done in a simple computation, using the $U^{-1}R$-linearity of ϱ and φ

$$\varrho\overline{\pi}\left(\frac{1}{u}\pi(x)\right) \;=\; \frac{1}{u}\varrho\pi(x) \;=\; \frac{1}{u}\varphi\kappa(x) \;=\; \frac{1}{u}\varphi\left(\frac{x}{1}\right) \;=\; \varphi\left(\frac{x}{1}\right)$$

- Suppose I is an injective R-module, then we would like to verify that $U^{-1}I$ is an injective $U^{-1}R$-module. One of the equivalent properties of being injective is the following: given a sub-module $Q \leq_{\mathfrak{m}} I$ of I there already in another sub-module $P \leq_{\mathfrak{m}} I$ such that $I = P + Q$ and $P \cap Q = 0$ (that is Q is a direct summand of I). Thus consider any $U^{-1}R$-sub-module $Q \leq_{\mathfrak{m}} U^{-1}I$. According to (3.127) Z corresponds to a sub-module $Q \leq_{\mathfrak{m}} I$ of I by virtue of $Z = U^{-1}Q$. And due to the injectivity this gives rise to $P \leq_{\mathfrak{m}} I$ as described above. Now let $Y := U^{-1}P \leq_{\mathfrak{m}} U^{-1}I$ then it is clear, that $Y + Z \subseteq U^{-1}I$. Conversely consider any $x/u \in U^{-1}I$, that is $u \in U$ and $x \in I$. As $I = P + Q$ there are some $p \in P$ and $q \in Q$ such that $x = p + q$. But from this we get $x/u = (p+q)/u = p/u + q/u \in Y + Z$. It remains to verify $Y \cap Z = 0$ but this follows from (3.127) again

$$Y \cap Z \;=\; U^{-1}P \cap U^{-1}Q \;=\; U^{-1}\Big(P \cap Q\Big) \;=\; U^{-1}0 \;=\; 0$$

□

Proof of (3.135):
Clearly (a) $\Longrightarrow$ (b) and (b) $\Longrightarrow$ (c) are trivial. Hence we only need to consider (c) $\Longrightarrow$ (a). Thus suppose we had (c) but $M \neq 0$. That is we could choose some $x \in M$ with $x \neq 0$. Then we take to

the annihilator $\mathfrak{a} := \mathrm{ann}(x) := \{\, a \in R \mid ax = 0 \,\}$ of x. As $x \neq 0$ we have $\mathfrak{a} \neq R$ and hence (2.4.(ii)) tells us that $\mathfrak{a}$ is contained $\mathfrak{a} \subseteq \mathfrak{m}$ inside a maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$. By assumption we have $M_{\mathfrak{m}} = 0$ in particular $x/1 = 0/1$ in $M_{\mathfrak{m}}$. This means there is some $w \in U = R \setminus \mathfrak{m}$ such that $wx = 0$. But by definition of $\mathfrak{a}$ this is $w \in \mathfrak{a} \subseteq \mathfrak{m}$. This of course is a contradiction and hence we have $M = 0$. □

Proof of (3.136):
In a first step we will prove that $x = 0$ is equivalent to $x/1 = 0/1$ in $M_{\mathfrak{m}}$ for any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$. Let us denote $L := Rx$ the sub-module of M generated by x. Then $x = 0$ is equivalent to $L = 0$. And due to (3.135) this again is equivalent to $L_{\mathfrak{m}} = 0$ for any $\mathfrak{m} \in \mathrm{Smax}(R)$. As L is generated by x we know that $L_{\mathfrak{m}}$ is generated by $x/1$ - that is $L_{\mathfrak{m}} = R_{\mathfrak{m}}(x/1)$ according to (3.131.(ii)). Hence $L_{\mathfrak{m}} = 0$ is equivalent to $x/1 = 0/1$ and altogether we have

$$x = 0 \iff \forall\, \mathfrak{m} \in \mathrm{Smax}(R) \,:\, \frac{x}{1} = \frac{0}{1}$$

Now consider the sub-module $P \leq_{\mathfrak{m}} M$. Then $x \in P$ is equivalent to $x + P = 0 + P$ in the quotient module M/P. And by the above this is equivalent to $(x + P)/1 = (0 + P)/1$ in $(M/P)_{\mathfrak{m}}$ (for any $\mathfrak{m} \in \mathrm{Smax}(R)$). We now use the isomorphy of the quotients as proved in (3.125.(i)). That is $(M/P)_{\mathfrak{m}} \xrightarrow{\sim} M_{\mathfrak{m}}/P_{\mathfrak{m}}$ under the isomorphism $(x + P)/u \mapsto x/u + P_{\mathfrak{m}}$. Applying this isomorphism we have found another equivalent reformulation: for any $\mathfrak{m} \in \mathrm{Smax}(R)$ we have $x/1 + P_{\mathfrak{m}} = 0/1 + P_{\mathfrak{m}}$ in $M_{\mathfrak{m}}/P_{\mathfrak{m}}$. And this again is $x/1 \in P_{\mathfrak{m}}$ for any $\mathfrak{m} \in \mathrm{Smax}(R)$, as has been claimed. □

Proof of (3.137):
The implications (a) $\implies$ (b) are either trivial or have been shown in (3.125.(ii)). Also the implication (b) $\implies$ (c), as every maximal ideal of R already is prime. It remains to verify (c) $\implies$ (a) in the respective cases: *Injective:* let $P := \mathrm{kn}(\varphi)$, then for any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ we have $P_{\mathfrak{m}} = \mathrm{kn}(\varphi_{\mathfrak{m}})$ according to (3.127.(ii)). And as any $\varphi_{\mathfrak{m}}$ is injective this makes $P_{\mathfrak{m}} = 0$. Now suppose we have some $x \in P$ then by (3.136) this is equivalent to $x/1 \in P_{\mathfrak{m}} = 0$ for any maximal ideal $\mathfrak{m}$, such that always $x/1 = 0/1$. But this again means $x = 0$, so we have proved $x \in \mathrm{kn}(\varphi) \implies x = 0$ which is the injectivity of φ.

Surjective: let $Q := \mathrm{im}(\varphi)$, then for any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ we have $Q_{\mathfrak{m}} = \mathrm{im}(\varphi_{\mathfrak{m}})$ according to (3.127.(ii)). And as any $\varphi_{\mathfrak{m}}$ is surjective this makes $Q_{\mathfrak{m}} = N_{\mathfrak{m}}$. Now pick up any $y \in N$, then $x/1 \in N_{\mathfrak{m}} = Q_{\mathfrak{m}}$ for any $\mathfrak{m} \in \mathrm{Smax}(R)$. And by (3.136) this implies $y \in Q = \mathrm{im}(\varphi)$. As y has been arbitrary this is the surjectivity of φ.

Bijective: if all the $\varphi_{\mathfrak{m}}$ are bijective, they are both injective and surjective. Hence by the above φ itself is injective and surjective, hence bijective, again. *Zero:* let $Q := \mathrm{im}(\varphi)$ again, then (as any $\varphi_{\mathfrak{m}} = 0$) this time we get $Q_{\mathfrak{m}} = 0$ for any maximal ideal $\mathfrak{m} \in R$. By (3.136) once more, this yields $Q = 0$ and hence $\varphi = 0$, as well. □

Proof of (3.133):
We first need to check that h is well-defined, that is consider any two homomorphisms $\varphi, \psi : M \to N$ and $u, v \in U$ such that $\varphi/u = \psi/v$. That is there is some $w \in U$ such that $wv\varphi = wu\varphi$. If we are now given any $x/q \in U^{-1}M$, then multiplying this equation with q and inserting x we get $wqv\varphi(x) = wqu\psi(x)$. And this again is $h(\varphi/u)(x/q) = \varphi(x)/qu = \psi(x)/qv = h(\psi/v)(x/q)$. And as x/q has been arbitrary this is $h(\varphi/u) = h(\psi/v)$. The next step is verifying the properties of an R-module homomorphism: that

is we consider φ/u and ψ/v again. Then $\varphi/u + \psi/v = (v\varphi + u\psi)/uv$, which is mapped to

$$h\left(\frac{\varphi}{u}+\frac{\psi}{v}\right)\left(\frac{x}{q}\right) \;=\; \frac{v\varphi(x)+u\psi(x)}{quv} \;=\; \frac{\varphi(x)}{qu}+\frac{\psi(x)}{qv}$$

That is the image of the sum of the homomorphisms $h(\varphi/u + \psi/v)$ is the sum of the images $h(\varphi/u) + h(\psi/v)$. Also it is straightforward to prove the $U^{-1}R$-linearity of h: as $(a/u)(\psi/v) = a\psi/uv$ we get

$$h\left(\frac{a}{u}\frac{\psi}{v}\right)\left(\frac{x}{q}\right) \;=\; \frac{a\psi(x)}{quv} \;=\; \frac{a}{u}\frac{\psi(x)}{qu}$$

To prove item (i) we assume that $M = \mathrm{Lh}_R\{\, m_1, \ldots, m_n \,\}$ for some $m_i \in M$. Now suppose we had $h(\varphi/u) = 0$ for some $\varphi : M \to N$ and $u \in U$. I.e. for any $x/q \in U^{-1}M$ we have $\varphi(x)/qu = 0/1$ and hence there is some $w \in U$ such that $w\varphi(x) = 0$. In particular we may choose some $w_i \in U$ such that $w_i\varphi(m_i) = 0$. Now let $w := w_1 \ldots w_n$ and $\widehat{w}_i := w/w_i \in U$. As the m_i generate M any $x \in M$ can be written as $x = a_1m_1 + \cdots + a_nm_n$ for some $a_i \in R$ such that the R-linearity of φ yields

$$w\varphi(x) \;=\; w\sum_{i=1}^{n} a_i\varphi(m_i) \;=\; \sum_{i=1}^{n} a_i\widehat{w}_i w_i\varphi(m_i) \;=\; 0$$

That is $w\varphi(x) = 0$ and as $x \in M$ has been arbitrary, this is $w\varphi = 0$. This again means $\varphi/u = 0/1$ is the zero-homomorphism, shuch that the kernel of h is 0, which is the injectivity of h.

Let us now prove item (ii): If M admits a finite free presentation, then it is finitely generated already (see below). In particular we already know, that h is injective and it remains to prove the surjectivity of h. Recall that the finite free presentation is an exact chain of the form

$$R^m \;\xrightarrow{\;\alpha\;}\; R^n \;\xrightarrow{\;\omega\;}\; M \to 0$$

Reasoning: let e_i (where $i \in 1 \ldots m$) be the Euclidean basis of R^m. As ω is surjective the $m_i := \omega(e_i)$ (where $i \in 1 \ldots m$) build up a generating set of M and hence $\mathrm{rank}(M) \leq m$ is finitely generated. In particular, according to (3.131.(i)), $U^{-1}M$ is generated by the $m_i/1$ (where $i \in 1 \ldots m$). Let us now pick up the Euclidean basis $f_j \in R^n$ (where $j \in 1 \ldots n$) of R^n as well and denote $A_j := \alpha(f_j) \in R^m$. That is $A_j = (A_{1,j}, \ldots, A_{m,j})$ for some $A_{i,j} \in R$. That is, if $a = (a_1, \ldots, a_n) \in R^n$ then we have

$$\alpha(a) \;=\; \sum_{j=1}^{n} a_j\alpha(f_j) \;=\; \sum_{j=1}^{n} a_j \sum_{i=1}^{m} A_{i,j}e_i \;=\; \sum_{i=1}^{m}\left(\sum_{j=1}^{n} A_{i,j}a_j\right)e_i$$

As $\mathrm{im}(\alpha) = \mathrm{kn}(\omega)$ we have (for any $b \in R^m$) the equivalence $\omega(b) = 0$ if and only if $b = \alpha(a)$ for some $a \in R^n$. Writing $b = (b_1, \ldots, b_m) \in R^m$ again we see $\omega(b) = \sum_i b_i\omega(e_i) = \sum_i b_im_i$ such that this equivalence turns into

$$\sum_{i=1}^{m} b_im_i = 0 \quad\Longleftrightarrow\quad \exists\, a \in R^n \;\; \forall\, j \in 1 \ldots n \;\;:\;\; b_i = \sum_{j=1}^{n} A_{i,j}a_j$$

In particular $\omega(A_j) = \sum_i A_{i,j}m_i = 0$ since $A_j = \alpha(f_j)$ for any $j \in 1 \ldots n$. Then, in the localization $U^{-1}M$

of M, we get the equality

$$\frac{0}{1} \;=\; \frac{\sum_{i=1}^m A_{i,j} m_i}{1} \;=\; \sum_{i=1}^m \frac{A_{i,j}}{1}\frac{m_i}{1}$$

After all these preparations suppose we are given some $U^{-1}R$-module homomorphism $\psi : U^{-1}M \to U^{-1}N$. Let us denote $n_i/u_i := \psi(m_i/1)$ for some $n_i \in N$ and $u_i \in U$. Let us also denote $u := u_1 \cdot \dots \cdot u_m$ and $\widehat{u}_i := u/u_i \in U$ as usual. Note that ψ is determined by its action on the $m_i/1$, as these elements generate $U^{-1}M$. Then due to the linearity of ψ the above equation turns into the following equation of $U^{-1}N$

$$\frac{0}{1} \;=\; \psi\left(\sum_{i=1}^m \frac{A_{i,j}}{1}\frac{m_i}{1}\right) \;=\; \sum_{i=1}^m \frac{A_{i,j}}{1}\frac{n_i}{u_i} \;=\; \frac{\sum_{i=1}^m A_{i,j}\widehat{u}_i n_i}{u}$$

By definition of the localization that is (for any $j \in 1 \dots n$) there is some $w_j \in U$ such that $w_j \sum_i A_{i,j}\widehat{u}_i n_i = 0$. Again we denote $w := w_1 \cdot \dots \cdot w_n$ and $\widehat{w}_j := w/w_j \in U$. This enables us to define or candidate for the R-module homomorphism $\varphi : M \to N$ by linear expansion of $\varphi(m_i) := w\widehat{u}_i n_i$. If this is well-defined then it automatically yields an R-linear map. To prove the well-definedness we have to regard $\sum_i a_i m_i = \sum_i a'_i m_i$ and need to show that this implies $\sum_i a_i w\widehat{u}_i n_i = \sum_i a'_i w\widehat{u}_i n_i$. By going to differences $b_i = a'_i - a_i$ it hence suffices to check

$$\sum_{i=1}^m b_i m_i \;=\; 0 \quad\Longrightarrow\quad \sum_{i=1}^m b_i w\widehat{u}_i n_i \;=\; 0$$

But due to $\mathrm{im}(\alpha) = \mathrm{kn}(\omega)$ we have seen above that $\sum_i b_i m_i = 0$ is equivalent to $b_i = \sum_j A_{i,j} a_j$ for some $a_j \in R$ and any $i \in 1 \dots m$. Hence the latter sum turns into

$$\sum_{i=1}^m b_i w\widehat{u}_i n_i \;=\; \sum_{i=1}^m \sum_{j=1}^n A_{i,j} a_j w\widehat{u}_i n_i \;=\; \sum_{j=1}^n a_j \widehat{w}_j w_j \sum_{i=1}^m A_{i,j}\widehat{u}_i n_i \;=\; 0$$

by choice of the w_j (see above). That is φ is truly well-defined. And all we have left to do is check that $h(\varphi/uw) = \psi$. But as the $m_i/1$ generate $U^{-1}M$ it suffices to prove this for all the $m_i/1$. And this can be done in a last simple computation

$$\frac{U^{-1}\varphi(m_i/1)}{uw} \;=\; \frac{\varphi(m_i)}{uw} \;=\; \frac{w\widehat{u}_i n_i}{uw} \;=\; \frac{n_i}{u_i} \;=\; \varphi\left(\frac{m_i}{1}\right)$$

□

Proof of (2.134):

We have already proved (a) $\Longrightarrow$ (b) in (2.131) and (b) $\Longrightarrow$ (c) is trivial. Thus it only remains to verify (c) $\Longrightarrow$ (a): we denote $F := \mathrm{QUOT}(R)$ the quotient field of R and regard R and any localization $R_{\mathfrak{m}}$ as a sub-ring of R (also refer to (2.133) for this). Now regard any $x \in F$ integral over R, that is $f(x) = 0$ for some normed polynomial $f \in R[t]$. If we interpret $f \in R_{\mathfrak{m}}[t]$, then $f(x) = 0$ again and hence x is integral over $R_{\mathfrak{m}}$ (where $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ is any maximal ideal of R). By assumption $R_{\mathfrak{m}}$ is normal and hence $x \in R_{\mathfrak{m}}$ again. And as $\mathfrak{m}$ has been arbitrary the local global principle (2.133) yields:

$$x \;\in\; \bigcap_{\mathfrak{m}\in \mathrm{smax}R} R_{\mathfrak{m}} \;=\; R$$

□

Proof of (2.60): (continued)

- (c) $\implies$ (d): property (2) of (c) and (d) are identical so we only need to verify (1) in (d). If all $a_i = 0$ are zero then there is nothing to prove ($s := 0$). And if at least one $a_r \neq 0$ is non-zero, then so are all a_{r+i} for $i \in \mathbb{N}$. Omitting the a_0 to a_{r-1} we may assume $a_i \neq 0$ for any $i \in \mathbb{N}$. By assumption we have $a_i R \subseteq a_{i+1} R$ for any $i \in \mathbb{N}$. And this translates into $a_{i+1} \mid a_i$. By (2.64.(iii)) this yields a descending chain of natural numbers for any prime element $p \in R$

$$\langle p \mid a_0 \rangle \ \geq \ \langle p \mid a_1 \rangle \ \geq \ \ldots \ \geq \ \langle p \mid a_i \rangle \ \geq \ \ldots \geq 0$$

 Of course this means that the sequence $\langle p \mid a_i \rangle$ has to become startionary. That is there is some $s(p) \in \mathbb{N}$ such that for all $i \in \mathbb{N}$ we get $\langle p \mid a_{s(p)+i} \rangle = \langle p \mid a_{s(p)} \rangle$. We now choose a representing system $\mathbb{P}$ of the prime elements of R modulo associateness. Then there only are *finitely many* $p \in \mathbb{P}$ such that $\langle p \mid a_0 \rangle \neq 0$. And for those $p \in \mathbb{P}$ with $\langle p \mid a_0 \rangle = 0$ we may clearly take $s(p) = 0$. Thereby we may define

$$s \ := \ \max\{\, s(p) \mid p \in \mathbb{P} \,\} \ \in \ \mathbb{N}$$

 Then it is clear that for any $p \in \mathbb{P}$ and any $i \in \mathbb{N}$ we get $\langle p \mid a_{s+i} \rangle = \langle p \mid a_s \rangle$. And by (2.64.(iv)) this is nothing but $a_{s+i} \approx a_s$ which again translates into $a_{s+i} R = a_s R$. And this is just what had to be proved.

- (d) $\implies$ (c): property (2) of (c) and (d) are identical so we only need to verify (1) in (c). But the proof of this would be a literal repetition of (2.59.(iii)). There we have proved the existence of an irreducible decomposition using the ascending chain condition of noetherian rings. But in fact this property has only been used for principal ideals and hence is covered by the assumption (1) in (d). Hence the same proof can be applied here, too.

- (a) $\implies$ (e): As $\mathfrak{p} \neq 0$ is non-zero, there is some $0 \neq a \in R$ with $a \in \mathfrak{p}$. Clearly $a \notin R^*$ as else $\mathfrak{p} = R$. We now use a prime decomposition of a, that is $\alpha p_1 \ldots p_k = a \in \mathfrak{p}$. Thereby $k \geq 1$ as else $a \in R^*$. And as $\mathfrak{p}$ is prime we either get $\alpha \in \mathfrak{p}$ or $p_i \in \mathfrak{p}$ for some $i \in 1 \ldots k$. But again $\alpha \in \mathfrak{p}$ would yield $\mathfrak{p} = R$ which cannot be. Thus $p := p_i \in \mathfrak{p}$ where p is prime by construction.

- (e) $\implies$ (f): We assume $R \neq 0$ (else the stetements herin do not make sense!). It is clear that $0 \notin D$ (as R is an integral domain $\alpha \in R^*$ and $p_i \neq 0$). Therefore $D \subseteq R \setminus \{0\}$ such that we obtain the canonical homomorphism

$$D^{-1}R \to \mathrm{quot}(R) \ : \ \frac{a}{d} \mapsto \frac{a}{d}$$

 Due to $0 \notin D$ we also see that $D^{-1}R \neq 0$ is not the zero-ring. Therefore $D^{-1}R$ contains a maximal ideal $\mathfrak{u} \trianglelefteq_{\mathrm{i}} D^{-1}R$ - by (2.4.(iv)) - such that $\mathfrak{p} := \mathfrak{u} \cap R \in D^{-1}\mathrm{Smax}(R)$ is maximal too - by (2.129) - in particular prime. Suppose $\mathfrak{p} \neq 0$ then by assumption (e) there is some prime element $p \in \mathfrak{p}$. And thereby $p \in \mathfrak{p} \cap D$ in contradiction to $\mathfrak{p} \in D^{-1}\mathrm{Smax}(R)$. Thus $\mathfrak{p} = 0$ and therefore $\mathfrak{u} = D^{-1}\mathfrak{p} = 0$, too. But $0 \in D^{-1}R$ being maximal yields that $D^{-1}R$ is a field. In particular the canonical homomorphism is injective (as it is non-zero). Now choose any $a/b \in \mathrm{quot}(R)$ then a, $b \in R$ and hence $a/1$, $b/1 \in D^{-1}R$. Yet $b \neq 0$ and hence $(1/b)^{-1} = 1/b \in D^{-1}R$, as $D^{-1}R$ is a field. Therefore $a/b \in D^{-1}R$ such that the canonical homomorphism also is surjective. By

construction this even is an equality of sets.

- (f) $\implies$ (a): Consider any $0 \neq a \in R$. Then $1/a \in \text{QUOT}(R) = D^{-1}R$, that is there are $b \in R$ and $d \in D$ such that $1/a = b/d$. And as R is an integral domain this is $ab = d \in D$. Yet D is saturated by (2.58.(vi)) and therefore $a \in D$. But this just means that a admits a prime decomposition.

□

Proof of (2.90):
We have already proved statements (i) to (vii) on page (1059), so it only remains to prove statement (viii). We have already seen in (vii) that the map $\mathfrak{b} \mapsto \mathfrak{b} \cap R = \kappa^{-1}(\mathfrak{b})$ is well-defined (as $\kappa^{-1}(\mathfrak{q}) = \mathfrak{q} \cap R = \mathfrak{p}$ again). Thus we next check the well-definedness of $\mathfrak{a} \mapsto U^{-1}\mathfrak{a}$. First of all we have $\sqrt{U^{-1}\mathfrak{a}} = U^{-1}\sqrt{\mathfrak{a}} = U^{-1}\mathfrak{p} = \mathfrak{q}$ due to (2.125). Now consider a/u and $b/v \in U^{-1}R$ such that $(ab)/(uv) = (a/u)(b/v) \in U^{-1}\mathfrak{a}$ but $b/v \notin U^{-1}R$. Then $ab \in (U^{-1}\mathfrak{a}) \cap R = \mathfrak{a} : U$, that is there is some $w \in U$ such that $abw \in \mathfrak{a}$. But $bw \notin \mathfrak{a}$, as else $b/v = (bw)/(vw) \in U^{-1}\mathfrak{a}$. As $\mathfrak{a}$ is primary this implies $a \in \sqrt{\mathfrak{a}} = \mathfrak{p}$ and hence $a/u \in U^{-1}\mathfrak{p} = \mathfrak{q} = \sqrt{U^{-1}\mathfrak{a}}$. This means that $U^{-1}\mathfrak{a}$ is primary again and hence $\mathfrak{a} \mapsto U^{-1}\mathfrak{a}$ is well-defined. □

Proof of (2.19):

(i) As the union ranges over all prime ideals $\mathfrak{p}$ with $\mathfrak{p} \subseteq \text{ZD}(R)$ it is clear that the union is contained in $\text{ZD}(R)$ again. That is the incluison " $\supseteq$ " is trivial. For the converse inclusion let us denote $U := \text{NZD}R$, then U is multiplicatively closed. Let now $a \in \text{ZD}(R)$ be a zero-divisor. That is we may choose some $0 \neq b \in R$ such that $ab = 0$. This implies $aR \subseteq \text{ZD}(R)$ (because given any $x \in R$ we get $(ax)b = x(ab) = x0 = 0$) or in other words $aR \cap U = \emptyset$. Thus by (2.4.(iii)) we may choose an ideal $\mathfrak{p}$ maximal among the ideals satisfying $aR \subseteq \mathfrak{b} \subseteq R \setminus U = \text{ZD}(R)$ and this is prime. In particular $a \in \mathfrak{p}$ such that a is also contained in the union of prime ideals contained in $\text{ZD}(R)$.

(ii) Let $\mathfrak{p}$ be a minimal prime ideal of R, then by the correspondence theorem (2.129) the spectrum of the localized ring $R_\mathfrak{p}$ corresponds to

$$\text{Spec}(R_\mathfrak{p}) \longleftrightarrow \{\, \mathfrak{q} \in \text{Spec}(R) \mid \mathfrak{q} \subseteq \mathfrak{p} \,\} \longleftrightarrow \{\, \mathfrak{p} \,\}$$

Hence $R_\mathfrak{p}$ has precisely one prime ideal, namely the ideal $\overline{\mathfrak{p}} = (R \setminus \mathfrak{p})^{-1}\mathfrak{p}$ corresponding to $\mathfrak{p}$. And by (2.22.(v)) this yields

$$\text{NIL}(R_\mathfrak{p}) = \bigcap \text{Spec}(R_\mathfrak{p}) = \overline{\mathfrak{p}}$$

Now consider any $a \in \mathfrak{p}$, then $a/1 \in \overline{\mathfrak{p}}$ and hence there is some $k \in \mathbb{N}$ such that $a^k/1 = (a/1)^k = 0/1$. That is there is some $u \in R \setminus \mathfrak{p}$ such that $ua^k = 0$. But $k \neq 0$ as else $u = 0 \in \mathfrak{p}$. Hence we may choose $1 \leq k$ minimally such that $ua^k = 0$. Then we let $b := ua^{k-1}$ and thereby get $b \neq 0$ (as k has been minimal) and $ab = 0$. That is $a \in \text{ZD}(R)$ and hence $\mathfrak{p} \subseteq \text{ZD}R$ (as a has been arbitrary).

(iii) As R is commutative, we know from (1.47.(vi)) that $\text{NIL}(R)$ is an ideal. If $R = 0$, then $R/\text{NIL}(R) = 0$ is the zero-ring, too. Hence neither of these rings has any prime ideal and hence $\emptyset \longleftrightarrow \emptyset$ is trivial. So let now $R \neq 0$ and consider any prime ideal $\mathfrak{p} \trianglelefteq_\text{i} R$ and any $a \in R$ with $a^n = 0 \in \mathfrak{p}$. If $n = 0$ then $1 = 0$, which we excluded by $R \neq 0$. As $\mathfrak{p}$ is a prime ideal, we conclude $a \in \mathfrak{p}$. And as $\mathfrak{p}$ and a have been arbitrary, this means $\text{NIL}(R) \subseteq \mathfrak{p}$. Then the claim is just a special case of the

correspondence theorem of ideals (1.71) in quotient rings:

$$\operatorname{Spec}\left(R \big/ \operatorname{NIL}(R)\right) \;\longleftrightarrow\; \{\, \mathfrak{p} \in \operatorname{Spec}(R) \mid \operatorname{NIL}(R) \subseteq \mathfrak{p} \,\} \;=\; \operatorname{Spec}(R)$$

□

Proof of (2.135):
(b) $\Longrightarrow$ (a): of course $R = 0$ cannot occur, as else $R^* = R$ and hence $R \setminus R^* = \emptyset$ was no ideal of R. Thus $R \neq 0$ and hence R contains a maximal ideal, by (2.4.(iv)). And if $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ is any maximal ideal of R then we have $\mathfrak{m} \neq R$ and hence $\mathfrak{m} \subseteq R \setminus R^* \neq R$. By maximality of $\mathfrak{m}$ we get $\mathfrak{m} = R \setminus R^*$ which also is the uniqueness of the maximal ideal. (a) $\Longrightarrow$ (b): let $\mathfrak{m}$ be the one and only maximal ideal of R. As $\mathfrak{m} \neq R$ we again get $\mathfrak{m} \subseteq R \setminus R^*$. Conversely, if $a \in R \setminus R^*$ then $aR \neq R$. Hence there is a maximal ideal containing aR, by (2.4.(ii)). But the only maximal ideal is $\mathfrak{m}$ such that $a \in aR \subseteq \mathfrak{m}$. And as a has been arbitrary this proves $R \setminus R^* \subseteq \mathfrak{m}$ and hence $\mathfrak{m} = R \setminus R^*$. In particular $R \setminus R^*$ is an ideal of R. □

Proof of (2.136):
(a) $\Longrightarrow$ (b): consider any $\mathfrak{a} \neq R$, then by (2.4.(ii)) $\mathfrak{a}$ is contained in some maximal ideal, and the only maximal ideal available is $\mathfrak{m}$, such that $\mathfrak{a} \subseteq \mathfrak{m}$. (b) $\Longrightarrow$ (a): first of all $\mathfrak{m}$ is a maximal ideal, as (due to (b)) $\mathfrak{m} \subseteq \mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ implies $\mathfrak{m} = \mathfrak{a}$ or $\mathfrak{a} = R$. And if $\mathfrak{n} \trianglelefteq_{\mathrm{i}} R$ is any maximal ideal of R, then we have $\mathfrak{n} \neq R$ and hence (due to (b)) $\mathfrak{n} \subseteq \mathfrak{m}$. But by maximality of $\mathfrak{n}$ and $\mathfrak{m} \neq R$ we now conclude $\mathfrak{n} = \mathfrak{m}$. Altogether we have $\operatorname{Smax}(R) = \{\mathfrak{m}\}$ as claimed. (a) $\Longrightarrow$ (c): has already been proved in (2.135) - in the form $R \setminus R^* = \mathfrak{m}$. (c) $\Longrightarrow$ (d) is trivial, so it only remains to prove the implication (d) $\Longrightarrow$ (b): consider any ideal $\mathfrak{a} \neq R$ again, then we have $\mathfrak{a} \subseteq R \setminus R^*$ and due to (d) this yields $\mathfrak{a} \subseteq R \setminus R^* \subseteq \mathfrak{m}$. □

Proof of (2.138):
First of all any $R \setminus \mathfrak{q}_i$ is multiplicatively closed, as $\mathfrak{q}_i$ is a prime ideal. The intersection of multiplicatively closed sets is multiplicatively closed again, so $U = R \setminus Q$ is multiplicatively closed.By the correspondence theorem (2.129) we know that the prime spectrum of $U^{-1}R$ is given to be

$$\operatorname{Spec}(U^{-1}R) \;=\; \left\{\, U^{-1}\mathfrak{p} \mid \mathfrak{p} \in \operatorname{Spec}(R), \mathfrak{p} \cap U = \emptyset \,\right\}$$

But $\mathfrak{p} \cap (R \setminus Q) = \emptyset$ is equivalent to $\mathfrak{p} \subseteq Q$, where $Q = \mathfrak{q}_1 \cup \cdots \cup \mathfrak{q}_n$. Now by prime avoidance (2.14.(iii)) there is some $i \in 1 \ldots n$ such that $\mathfrak{p} \subseteq \mathfrak{q}_i$. If $\mathfrak{q}_i$ is not maximal in $\mathcal{Q}$ itself, then there is a maximal $\mathfrak{q}_j \in \mathcal{Q}$ containing $\mathfrak{q}_i \subseteq \mathfrak{q}_j$. And of course if $\mathfrak{p} \subseteq \mathfrak{q}$ for some $\mathfrak{q} \in \mathcal{Q}^*$ then $\mathfrak{p} \subseteq Q$ is a given. Hence we can reformulate $\operatorname{Spec}(U^{-1}R)$ as claimed:

$$\operatorname{Spec}(U^{-1}R) \;=\; \left\{ U^{-1}\mathfrak{p} \;\middle|\; \begin{array}{l} \mathfrak{p} \in \operatorname{Spec}(R) \text{ such that} \\ \exists\, \mathfrak{q} \in \mathcal{Q}^* \ldots n : \mathfrak{p} \subseteq \mathfrak{q} \end{array} \right\}$$

Next we prove the equality for the maximal ideals: By the correspondence theorem (2.129) we also know that the maximal ideals of $U^{-1}R$ correspond to the ideals $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ that are maximal with respect to the property $\mathfrak{a} \subseteq Q$. That is

$$\operatorname{Smax}(U^{-1}R) \;=\; \left\{ U^{-1}\mathfrak{m} \;\middle|\; \begin{array}{l} \mathfrak{m} \trianglelefteq_{\mathrm{i}} R \text{ with } \mathfrak{m} \subseteq Q \text{ and} \\ \mathfrak{m} \subseteq \mathfrak{a} \subseteq Q \implies \mathfrak{m} = \mathfrak{a} \end{array} \right\}$$

In particular any ideal $\mathfrak{q} \in \mathcal{Q}^*$ qualifies for this property, as $\mathfrak{q} \subseteq \mathfrak{a} \subseteq Q$ implies $\mathfrak{q} \subseteq \mathfrak{a} \subseteq \mathfrak{q}_i$ for some

$i \in 1 \ldots n$ and hence $\mathfrak{q} = \mathfrak{q}_i$ such that $\mathfrak{q} = \mathfrak{a}$. Conversely, if $\mathfrak{m} \subseteq Q$ is any ideal, then we already have $\mathfrak{m} \subseteq \mathfrak{q}_i$ for some $i \in 1 \ldots n$ by prime avoidance, again. Pick up a maximal ideal $\mathfrak{q}_j \in \mathcal{Q}^*$ containing $\mathfrak{q}_i \subseteq \mathfrak{q}_j$. Then we have $\mathfrak{m} \subseteq \mathfrak{q}_j \subseteq Q$ such that by assumption of $\mathfrak{m}$ we get $\mathfrak{m} = \mathfrak{q}_j \in \mathcal{Q}^*$. Therefore the $U^{-1}\mathfrak{q}_j$ with $\mathfrak{q}_j \in \mathcal{Q}^*$ are the only maximal ideals of $U^{-1}R$.

$$\operatorname{Smax}(U^{-1}R) \;=\; \left\{ U^{-1}\mathfrak{m} \mid \mathfrak{m} \in \mathcal{Q}^* \right\}$$

If $\mathcal{Q} = \{ \mathfrak{p} \}$ contains one element only, then $\mathcal{Q}^* = \{ \mathfrak{p} \}$, as there is no other ideal in $\mathcal{Q}$ that could be larger. In particular $U^{-1}\mathfrak{p} = \mathfrak{m}_\mathfrak{p}$ is the one and only maximal ideal of $U^{-1}R = R_\mathfrak{p}$ as we have just argued above. That is $R_\mathfrak{p}$ is a local ring.with maximal ideal $\mathfrak{m}_\mathfrak{p}$.
Now regard $R_\mathfrak{p} \twoheadrightarrow \operatorname{QUOT}(R)/\mathfrak{p} : a/u \mapsto (a+\mathfrak{p})/(u+\mathfrak{p})$. This is well-defined and surjective, since $u + \mathfrak{p} \neq 0 + \mathfrak{p}$ if and only if $u \notin \mathfrak{p}$. And since $R/\mathfrak{p}$ is an integral domain we have $(a+\mathfrak{p})/(u+\mathfrak{p}) = (0+\mathfrak{p})/(1+\mathfrak{p})$ if and only if $a + \mathfrak{p} = 0 + \mathfrak{p}$ which is equivalent to $a \in \mathfrak{p}$ again. Thus the kernel of this epimorphism is just $\mathfrak{m}_\mathfrak{p}$ and hence it induces the isomorphism given. □

Proof of (2.139):
Let us begin with (a) $\implies$ (b): If the radical $\sqrt{\mathfrak{a}} = \mathfrak{m} \in \operatorname{Smax}(R)$ is a maximal ideal, then $\mathfrak{a}$ is a primary ideal, according to (2.90.(iii)) and $\sqrt{\mathfrak{a}} = \mathfrak{m}$ was a given. The next step is (b) $\implies$ (c): As $\mathfrak{a} \subseteq \sqrt{\mathfrak{a}}$ is generally true and $\sqrt{\mathfrak{a}} = \mathfrak{m}$ is part of the assumption, we have $\mathfrak{a} \subseteq \mathfrak{m}$. Now consider any $\mathfrak{p} \in \operatorname{Spec}(R)$ with $\mathfrak{a} \subseteq \mathfrak{p} \subseteq \mathfrak{m}$. Then, as any prime ideal is radical, we clearly have $\mathfrak{m} = \sqrt{\mathfrak{a}} \subseteq \sqrt{\mathfrak{p}} = \mathfrak{p} \subseteq \mathfrak{m}$. From this we get $\mathfrak{p} = \mathfrak{m}$, which means that $\mathfrak{m}$ is minimal over $\mathfrak{a}$. Now for (c) $\implies$ (d): As $\mathfrak{a} \subseteq \mathfrak{m}$ and $\mathfrak{m}$ is a maximal (and hence prime) ideal, we have $\mathfrak{m} \in \mathbb{V}(\mathfrak{a})$. Conversely consider any $\mathfrak{p} \in \mathbb{V}(\mathfrak{a})$, that is $\mathfrak{p}$ is a prime ideal with $\mathfrak{a} \subseteq \mathfrak{p}$. As $\mathfrak{p} \neq R$ (any prime ideal is proper, by definition) there is a maximal ideal containing $\mathfrak{p}$, by (2.4.(ii)). But $\mathfrak{m}$ is the only prime ideal available, in R, as R was assumed to be a local ring. That is $\mathfrak{p} \subseteq \mathfrak{m}$. Together this is $\mathfrak{a} \subseteq \mathfrak{p} \subseteq \mathfrak{m}$ and by assumption (c) this is $\mathfrak{p} = \mathfrak{m}$. Therefore $\mathbb{V}(\mathfrak{a}) = \{\mathfrak{m}\}$. We finally go full circle, (d) $\implies$ (a): By (2.32) we have $\sqrt{\mathfrak{a}} = \mathbb{IV}(\mathfrak{a}) = \bigcap\{\mathfrak{m}\} = \mathfrak{m}$, just what we needed. □

Proof of (2.142):

(U) As $R \neq 0$ we have $1 \neq 0$ and hence by property (1) we find $\nu(1) \in \mathbb{N}$. Thus by (2) we get $\nu(1) = \nu(1 \cdot 1) = \nu(1) + \nu(1) \in \mathbb{Z}$. And together this implies $\nu(1) = 0$. Now consider any $\alpha \in R^*$ then by (2) again $0 = \nu(1) = \nu(\alpha\alpha^{-1}) = \nu(\alpha) + \nu(\alpha^{-1}) \geq \nu(\alpha) \geq 0$ hence $\nu(\alpha) = 0$.

(I) If we are given $a, b \in R$ with $ab = 0$ then by (1) and (2) we have $\infty = \nu(ab) = \nu(a) = \nu(b)$. Thus $\nu(a)$ and $\nu(b)$ may not both be finte and by (1) this means $a = 0$ or $b = 0$.

(P) First of all $0 \in [\nu]$ as by (1) we have $\nu(0) = \infty \geq 1$ and $1 \notin [\nu]$ as $\nu(1) = 0 < 1$ by (U). If now a, $b \in [\nu]$ and $c \in R$ then we compute

$$\begin{aligned} \nu(a+b) &\;\geq\; \min\{\,\nu(a), \nu(b)\,\} \;\geq\; 1 \\ \nu(ac) &\;=\; \nu(a) + \nu(c) \;\geq\; \nu(a) \;\geq\; 1 \end{aligned}$$

And hence $a + b$ and $ac \in [\nu]$ again. Hence $[\nu]$ truly is an ideal of R and $[\nu] \neq R$ as $1 \notin [\nu]$. Now suppose $ab \in [\nu]$ for some $a, b \in R$, that is $\nu(ab) = \nu(a) + \nu(b) \geq 1$. Then it cannot be that $\nu(a) = 0 = \nu(b)$ and hence $a \in [\nu]$ or $b \in [\nu]$, which means $[\nu]$ is prime.

(iii) It is clear that $1 \mid a$ for any $a \in R$ and hence $0 \in \{k \in \mathbb{N} \mid p^k \mid a\}$. Therefore $[a]_p \in \mathbb{N} \cup \{\infty\}$ is well-defined.

- As any $p^k \mid 0$ it is clear that $\nu(0) = \infty$. Conversely suppose that $\nu(a) = \infty$ for some $a \in R$. Then for any $k \in \mathbb{N}$ we may choose some $a_k \in R$ such that $a = p^k a_k$. Then $p^{k+1}a_{k+1} = a = p^k a_k$ and as R is an integral domain this implies $pa_{k+1} = a_k$, in particular $a_{k+1} \mid a_k$. Going to ideals this yields an ascending chain

$$a_0 S \subseteq a_1 S \subseteq \ldots \subseteq a_k S \subseteq \ldots$$

 As R is noetherian there is some $s \in \mathbb{N}$ such that $a_s R = a_{s+1} R$, i.e. there is some $\alpha \in R^*$ such that $a_{s+1} = \alpha a_s = \alpha p a_{s+1}$. If $a_{s+1} \neq 0$ this would mean $p = \alpha^{-1}$ (as R is an integral domain) which is absurd, since p is prime. Thus we have $a_{s+1} = 0$ and hence $a = p^{s+1}a_{s+1} = 0$.

- If $g = 0$ then $\nu(fg) = \infty = \nu(f) + \nu(g)$, thus we only need to consider $0 \neq f, g \in R$. Now write $f = p^k a$ and $g = p^l b$ where $k = [f]_p$ and $l = [g]_p$, then by maximality we have $p \nmid a$ and $p \nmid b$ and hence $p \nmid ab$, since p is prime. Hence $\nu(fg) = \nu(p^{k+l}ab) = k + l = \nu(f) + \nu(g)$.

- If $g = 0$ then $\nu(f+g) = \nu(f) = \min\{\nu(f), \nu(g)\}$, thus we only need to consider $0 \neq f, g \in R$. As above let us write $f = p^k a$ and $g = p^l b$ where $k = [f]_p$ and $l = [g]_p$. Without loss of generality we may assume $k \leq l$ then $f + g = p^k(a + p^{l-k}b)$ and hence $\nu(f+g) = \nu(p^k(a+p^{l-k}b)) = k + \nu(a + p^{l-k}b) \geq k = \min\{\nu(f), \nu(g)\}$. Thus by now ν is a valuation on R and it is normed, since $\nu(p) = 1$.

- Continuing with the previous item now prove the fifth property: i.e. we even have $k < l$. If we now had $p \mid a + p^{l-k}b$, then there would be some $h \in S$ such that $a = ph - p^{l-k}b$. But this would imply $p \mid a$ which is absurd, by maximality of k. Hence $\nu(f+g) = k = \min\{\nu(f), \nu(g)\}$.

(iv) $\nu \mapsto [\nu]$ is well-defined:
As ν is normed, we have $[\nu] \neq 0$. Hence $[\nu]$ is a non-zero-prime ideal, and as R is a PID this even implies maximality.

- $\mathfrak{m} \mapsto \nu_p$ is well-defined:
 If we have $pR = \mathfrak{m} = qR$ then there is some $\alpha \in R^*$ with $\alpha p = q$ and as $(\alpha p)^k \mid a \iff p^k \mid a$ we then also get $\nu_q = \nu_{\alpha p} = \nu_p$.

- $\mathfrak{m} \mapsto \nu_p \mapsto [\nu_p] = \mathfrak{m}$:
 It is clear that $[\nu_p] = pR$ and as also $\mathfrak{m} = pR$ by construction $[\nu_p] = \mathfrak{m}$.

- $\nu \mapsto [\nu] \mapsto \nu_p = \nu$:
 By construction we have $[\nu] = pR$, thus if $a \in R$ with $p \nmid a$ then $a \notin pR = [\nu]$ and hence $\nu(a) = 0$. And as ν is normed, there is some $q \in S$ such that $\nu(q) = 1$. Hence $q \in [\nu] = pR$, which means $p \mid q$. Therefore $1 \leq \nu(p)$ (as $p \in pR = [\nu]$) and $\nu(p) \leq \nu(q) = 1$ (as $p \mid q$) imply $\nu(p) = 1$. If now $f \in R$ is given aribtarily then we write $f = p^k a$ where $p \nmid a$, then $\nu(f) = k\nu(p) + \nu(a) = k = \nu_p(f)$. And hence $\nu = \nu_p$.

□

Proof of (2.146):

(i) The properties (1), (2) and (3) of valued rings and discrete valuation rings are identical. Hence it suffices to check that R is non-zero. But by (N) there is some $m \in R$ with $\nu(m) = 1 \neq \infty$ and by (1) this is $m \neq 0$. In particular $R \neq 0$.

(ii) We have already seen in (2.142.(i)) that $[\nu]$ is a prime ideal of R. Thus by (2.136) it suffices to check $R \setminus [\nu] \subseteq R^*$. Thus consider any $a \in R \setminus [\nu]$, that is $\nu(a) = 0 = \nu(1)$ and hence $\nu(1) \leq \nu(a)$ and $\nu(a) \leq \nu(1)$. By (4) this implies $1 \mid a$ and $a \mid 1$ which again is $a \approx 1$ or in other words $a \in R^*$.

(iii) By (i) and (2.142.(i)) we know that R is an integral domain. Thus consider $a, b \in R$ with $a \neq 0$, then we need to find some $q, r \in R$ such that $b = qa + r$ and ($r = 0$ or $\varepsilon(r) < \varepsilon(a)$). To do this we distinguish three cases: if $b = 0$, then we may choose $q := 0$ and $r := 0$. If $b \neq 0$ and $\nu(b) < \nu(a)$, then we may let $q := 0$ and $r := b$. Thus if $b \neq 0$ and $\nu(a) \leq \nu(b)$, then by (4) we get $a \mid b$. That is there is some $q \in R$ such that $b = qa$. Hence we are done by letting $r := 0$.

(iv) By induction on $k \in \mathbb{N}$ it is clear that $\nu(m^k) = k\nu(m) = k$. Thus for $\nu(a) = k = \nu(m^k)$ we obtain $a \mid m^k$ and $m^k \mid a$. That is $a \approx m^k$ are associates and hence there is some $\alpha \in R^*$ such that $a = \alpha m^k$. And the uniqueness of α is clear, as R is an integral domain.

(v) Let $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ be any ideal of R, combining (iii) and (2.79.(iii)) we know that R is a PID. That is there is some $a \in R$ such that $\mathfrak{a} = aR$. In case $a = 0$ we have $\mathfrak{a} = 0$, else using (iv) we may write a as $a = \alpha m^k$ for some $\alpha \in R^*$. Thus we have $\mathfrak{a} = aR = \alpha m^k R = m^k R$ as claimed.

(vi) As $\nu(0) = \infty \geq 0$ and $\nu(1) = 0 \geq 0$ we have $0, 1 \in R$. Also we have $\nu(-1) = \nu((-1)(-1)) = 2\nu(-1)$ such that $\nu(-1) = 0$ and hence $-1 \in R$, too. If now $a, b \in R$ then by (3) we get $a + b \in R$ and by (2) also $ab \in R$. Altogether R is a sub-ring of F. We will now prove that ν is a discrete valuation on R again. Properties (1), (2), (3) and (N) are inherited trivially. And for (4) we are given $a, b \in R$ with $\nu(a) \leq \nu(b)$. In case $b = 0$ we have $a \cdot 0 = 0 = b$ and hence $a \mid b$ trivially. Thus assume $b \neq 0$, then we have $0 \leq \nu(a) \leq \nu(b) < \infty$ and hence $a \neq 0$, as well. Therefore we may let $x := ba^{-1} \in F$. Then by (2) we get $\nu(b) = \nu(xa) = \nu(x) + \nu(a)$, such that $\nu(x) = \nu(b) - \nu(a) \geq 0$. This again means $x \in R$ and hence $a \mid b$. It only remains to verify, that F truly is the quotient field of R. Thereby the inclusion " $\supseteq$ " is trivial. Hence consider any $x \in F$, if $\nu(x) \geq 0$ then $x = x \cdot 1^{-1}$ and we are done. Else we have $\nu(x^{-1}) = -\nu(x) > 0$ and hence $x^{-1} \in R$. Thus we likewise obtain $x = 1 \cdot (x^{-1})^{-1}$.

□

Proof of (2.147):

- (a) $\Longrightarrow$ (c): If (R, ν) is a discrete valuation ring, then R already is a local ring (with maximal ideal $[\nu]$) and an Euclidean ring, due to (2.146). But the latter implies that R is a PID, by (2.79.(iii)). And of course R cannot be a field, as there is some $m \in R$ with $\nu(m) = 1$ (and hence we have both $m \neq 0$ and $m \notin R^*$ as else $\nu(m) = 0$).

- (c) $\Longrightarrow$ (d): As R is a PID it is a UFD according to (2.79.(ii)). Now consider two prime elements $p, q \in R$, that is the ideals pR and qR are non-zero prime ideals. Hence - as R is a PID - pR and qR already are maximal by (2.79.(i)). But as R also is local this means $pR = qR$.

- (d) $\implies$ (b): Choose any $0 \neq n \in R \setminus R^*$ which is possible, as R is not a field. As R is an UFD we may choose some prime factor m of n and let $\mathfrak{m} := mR$. Now consider any $0 \neq a \in R$, as R is an UFD a admits a primary decomposition $a = \alpha p_1 \dots p_k$. But by assumption any prime factor p_i is associated to m, that is a admits the representation $a = \omega m^k$ for some $\omega \in R^*$ and $k \in \mathbb{N}$. If we had $a \notin R^*$ then we necessarily have $k \geq 1$ and hence $a \in mR = \mathfrak{m}$. Thus we have proved $R \setminus R^* \subseteq \mathfrak{m}$. And as $m \notin R^*$ we have $\mathfrak{m} \neq R$ such that R is a local ring with maximal ideal $\mathfrak{m}$, according to (2.136). And this again yields $R \setminus \mathfrak{m} = R^*$ as claimed. Now suppose $0 \neq a \in \bigcap_k m^k R$, as we have seen we may write $a = \omega m^k$ for some $\omega \in R^*$ and $k \in \mathbb{N}$. But by assumption on a we also have $a = bm^{k+1}$ for some $b \in R$. Dividing by m^k (R is an integral domain) we get $\omega = bm$ and hence $m \in R^*$ - a contradiction. Thus we also got $\bigcap_k m^k R = 0$.

- (b) $\implies$ (a): Let $\nu : R \to \mathbb{N} \cup \{\infty\} : a \mapsto \sup\{k \in \mathbb{N} \mid m^k \mid a\}$, then we will prove that ν is a discrete valuation on R: (1) if $a = 0$ then for any $k \in \mathbb{N}$ we clearly have $m^k \mid a$ and hence $\nu(0) = \infty$. Conversely if $\nu(a) = \infty$, then we have $m^k \mid a$ for any $k \in \mathbb{N}$ and hence $a \in \bigcap_k m^k R = 0$. (2) and (3) are easy by definition of ν - refer to the proof of (2.142.(ii)) for this. (4) Consider a and $b \in R$ with $\nu(a) \leq \nu(b)$. If $b = 0$ then $a \mid b$ is clear, otherwise we write $a = \alpha m^i$ and $b = \beta m^j$ for $i = \nu(a)$ and $j = \nu(b)$. By maximality of i we get $m \nmid \alpha$ and hence $\alpha \in R \setminus mR = R^*$. Thus we may define $h := \alpha^{-1}\beta m^{j-i}$ and thereby obtain $ha = b$ such that $a \mid b$. (N) suppose $m^2 \mid m$, then there was some $h \in R$ such that $hm^2 = m$ and hence $hm = 1$, which is $m \in R^*$. But in this case we had $R^* = R \setminus mR = \emptyset$ - a contradiction. Thus we have $\nu(m) \leq 1$ which clearly is $\nu(m) = 1$.

- (c) $\implies$ (f): Any PID is a noetherian UFD and by (2.65) an UFD is a normal ring. And the maximal ideal $\mathfrak{m}$ is non-zero, as we would else find $R^* = R \setminus \mathfrak{m} = R \setminus \{0\}$, which would mean that R was a field. Thus let $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ be any prime ideal of R, if $\mathfrak{p} \neq 0$ is non-zero, then $\mathfrak{p}$ already is maximal, due to (2.79.(i)). But in this case we necessarily have $\mathfrak{p} = \mathfrak{m}$, as R was assumed to be local.

- (f) $\implies$ (e): First of all $\mathfrak{m}$ is a finitely generated R-module, as R is a noetherian ring. Thus if we had $\mathfrak{m} = \mathfrak{m}^2 = \mathfrak{m}\,\mathfrak{m}$ then (as $\mathrm{JAC}(R) = \mathfrak{m}$) Nakayama's lemma (3.44) would imply $\mathfrak{m} = 0$ - a contradiction. Thus we have $\mathfrak{m}^2 \subset \mathfrak{m}$, that is there is some $m \in \mathfrak{m}$ with $m \notin \mathfrak{m}^2$. In what follows we will prove $\mathfrak{m} = mR$. (1) First note that $m \neq 0$ (as else $m \in \mathfrak{m}^2$), thus by assumption and (2.25.(i)) we get

$$\sqrt{mR} \;=\; \bigcap \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid mR \subseteq \mathfrak{p} \,\} \;=\; \mathfrak{m}$$

 In particular $\mathfrak{m} \subseteq \sqrt{mR}$ and hence there is some $k \in \mathbb{N}$ such that $\mathfrak{m}^k \subseteq mR$, by (2.25.(vii)). And of course we may choose k minimal with this property (that is $\mathfrak{m}^{k-1} \not\subseteq mR$). Clearly $k = 0$ cannot occur (as $m \in \mathfrak{m}$ and hence m is not a unit of R). And if $k = 1$ we are done, as in this case we get $\mathfrak{m} \subseteq mR \subseteq \mathfrak{m}$. Thus in the following we will assume $k \geq 2$ and derive a contradiction. (2) by minimality of k there is some $a \in \mathfrak{m}^{k-1}$ with $a \notin mR$. Let $a\mathfrak{m} := \{ab \mid b \in \mathfrak{m}\}$, as $a \in \mathfrak{m}^{k-1}$ we have $a\mathfrak{m} \subseteq \mathfrak{m}^{k-1}\mathfrak{m} = \mathfrak{m}^k \subseteq mR$. Now let $x := a/m \in E$, where $E := \mathrm{QUOT}(R)$ is the quotient field of R. Then clearly $x \notin R$ (that is $m \nmid a$) as else $a \in mR$ in contradiction to the choice of a. (3) Now it is easy to see that $x\mathfrak{m} := \{xb \mid b \in \mathfrak{m}\}$ is a subset $x\mathfrak{m} \subseteq R$ of R: for any $b \in \mathfrak{m}$ we have $xb = ab/m \in (1/m)\,mR = R$. And in fact $x\mathfrak{m}$ even is an ideal $x\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ of R ($0 \in x\mathfrak{m}$ is clear, and obviously $x\mathfrak{m}$ is closed under $+$, $-$ and multiplication with elements of R). Now by construction we even get $x\mathfrak{m} \neq R$ (as else there would be some $b \in \mathfrak{m}$ such that $xb = 1$. But this

would imply $m = ab \in a\mathfrak{m} \subseteq \mathfrak{m}^k \subseteq \mathfrak{m}^2$ (as we assumed $k \geq 2$) in contradiction to the choice of m). Thus $x\mathfrak{m}$ is a proper ideal of R and as R is a local ring with maximal ideal $\mathfrak{m}$ this implies $x\mathfrak{m} \subseteq \mathfrak{m}$. (4) Let us now choose generators of $\mathfrak{m}$, say $\mathfrak{m} = b_1R + \cdots + b_nR$. As $x\mathfrak{m} \subseteq \mathfrak{m}$ there are coefficients $a_{i,j} \in R$ (where $j \in 1 \ldots n$) such that for any $i \in 1 \ldots n$

$$xb_i \;=\; a_{i,1}b_1 + \cdots + a_{i,n}b_n$$

Let us now define $b := (b_1, \ldots, b_n)$ and the $n \times n$ matrix $A := (a_{i,j})$ over R. Then the above equations can be reformulated as $Ab = xb$, that is $b \in \ker(x\mathbb{1} - A)$. Thereby $(x\mathbb{1} - A)$ is a $n \times n$ matrix over the field E and as it has a kernel we have $\det(x\mathbb{1} - A) = 0 \in E$. Thus if $f := \det(t\mathbb{1} - A) \in R[t]$ is the characteristic polynomial of A then we have $f(x) = \det(x\mathbb{1} - A) = 0$. But as R was assumed to be normal and as f is a normed polynomial over R, this implies $x = a/m \in R$ or in other words $a \in mR$, a contradiction. This contradiction can only be solved in case $k = 1$ and then we have already seen $\mathfrak{m} = mR$.

- (e) $\Longrightarrow$ (c): First of all R is not a field, as $\mathfrak{m}$ is a proper non-trivial ideal of R (that is $0 \neq \mathfrak{m} \neq R$). It remains to verify, that R is a PID, where $\mathfrak{m} = mR$ was assumed to be a principal ideal. To do this we first let $\mathfrak{z} := \bigcap_k \mathfrak{m}^k \trianglelefteq_{\mathrm{i}} R$, as R is noetherian $\mathfrak{z}$ is a finitely generated R-module. And further we have $\mathfrak{m}\mathfrak{z} = \mathfrak{z}$ ("$\subseteq$" is clear and conversely if $a \in \mathfrak{z}$ then for any $k \in \mathbb{N}$ there is some $h_k \in R$ such that $a = h_k m^k$. Therefore $a/m = h_{k+1}m^k$ for any $k \in \mathbb{N}$ and hence $a/m \in \mathfrak{z}$ which is $a \in \mathfrak{m}\mathfrak{z}$ again). As $\mathfrak{m} = \mathrm{JAC}(R)$ the lemma of Nakayama (3.44) implies that $\mathfrak{z} = 0$. We now define the following map

$$\nu \;:\; \trianglelefteq_{\mathrm{i}} R \to \mathbb{N} \cup \{\infty\} \;:\; \mathfrak{a} \mapsto \sup\Big\{\, k \in \mathbb{N} \mid \mathfrak{a} \subseteq \mathfrak{m}^k \,\Big\}$$

Obviously ν is well defined, as $\mathfrak{a} \subseteq R = \mathfrak{m}^0$ for any $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$. And if $\mathfrak{a} \neq R$, then $\mathfrak{a}$ is contained in some maximal ideal, which is $\mathfrak{a} \subseteq \mathfrak{m}$ and hence $\nu(\mathfrak{a}) \geq 1$. Now suppose $\nu(\mathfrak{a}) = \infty$, this means $\mathfrak{a} \subseteq \bigcap_k \mathfrak{m}^k = 0$ and hence $\mathfrak{a} = 0$. Of course both 0 and R are principal ideals. Thus consider any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ with $0 \neq \mathfrak{a} \neq R$. As we have just seen, this yields $1 \leq k := \nu(\mathfrak{a}) \in \mathbb{N}$. And as $\mathfrak{a} \not\subseteq \mathfrak{m}^{k+1}$ we may choose some $a \in \mathfrak{a}$ with $a \notin \mathfrak{m}^{k+1}$. As $\mathfrak{a} \subseteq \mathfrak{m}^k$ we in particular have $a \in \mathfrak{m}^k$, that is $a = \alpha m^k$ for some $\alpha \in R$. If we had $\alpha \in \mathfrak{m}$ then $a \in \mathfrak{m}^{k+1}$ would yield a contradiction. Hence $\alpha \in R \setminus \mathfrak{m} = R^*$ is a unit. Therefore we found $\mathfrak{m}^k = m^kR = \alpha m^kR = aR \subseteq \mathfrak{a} \subseteq \mathfrak{m}^k$ and hence $\mathfrak{a} = m^kR$ is a principal ideal. Altogether R is a PID.

□

Proof of (2.150):

(i) By definition of a local ring it suffices to check $R \setminus R^* \trianglelefteq_{\mathrm{i}} R$. As $R \neq 0$ we have $0 \in R \setminus R^*$. Now consider any $a, b \in R \setminus R^*$ and $r \in R$. Then $ra \in R \setminus R^*$, as else $a^{-1} = r(ar)^{-1}$ and in particular $-a \in R \setminus R^*$. It remains to show that $a + b \in R \setminus R^*$. Without loss of generality we may assume $a \mid b$ (else we may interchange a and b). That is $b = ab$ for some $h \in R$ and hence $a + b = a(1 + h)$. Thus we have $a + b \in R \setminus R^*$, as else $a^{-1} = (1 + h)(a + b)^{-1}$.

(i) By assumption R is an integral domain. Thus regard any finitely generated ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$. That is there are $a_1, \ldots, a_k \in R$ (where we may choose k minimally) such that $\mathfrak{a} = a_1R + \cdots + a_kR$. We

need to show that $\mathfrak{a}$ is a principal ideal, that is $k = 1$. Thus assume $k \neq 1$, then $\mathfrak{a} \neq a_1 R$ (as k is minimal) and hence there is some $b \in \mathfrak{a}$ such that $b \notin a_1 R$. Now write $b = a_1 b_1 + \cdots + a_k b_k$ and let $d := a_2 b_2 + \cdots + a_k b_k$. If we had $a_1 \mid d$ then $d \in a_1 R$ and hence $b = a_1 b_1 + d \in a_1 R$, a contradiction. Thus we have $d \mid a_1$ as R is a valuation ring. But this means $a_1 \in dR \subseteq a_2 R + \cdots + a_k R$ and hence $\mathfrak{a} = a_1 R + \cdots + a_k R = a_2 R + \cdots + a_k R$ in contradiction to the minimality of k. This only leaves $k = 1$ which had to be shown.

(ii) (c) $\Longrightarrow$ (b) is true by (2.146.(iii)) and (b) $\Longrightarrow$ (a) is clear. Thus it remains to verify (a) $\Longrightarrow$ (c): as R is a valuation ring, it is a Bezout domain, by (i). Thus if R also is noetherian it clearly is a PID. But R also is local by (i) and a local PID is a field or a DVR by (2.147).

□

Proof of (2.153):
It is clear that $\mathfrak{f} + \mathfrak{g}$, $\mathfrak{f} \cap \mathfrak{g}$ and $\mathfrak{f}\mathfrak{g}$ are R-sub-modules again. If now $r\mathfrak{f} \subseteq R$ and $s\mathfrak{g} \subseteq R$ then we can also check property (2) of fraction ideals

$$\begin{array}{rcccl} (rs)(\mathfrak{f}+\mathfrak{g}) & = & s(r\mathfrak{f}) + r(s\mathfrak{g}) & \subseteq & R \\ r(\mathfrak{f}\cap\mathfrak{g}) & \subseteq & r\mathfrak{f} & \subseteq & R \\ (rs)(\mathfrak{f}\mathfrak{g}) & = & (r\mathfrak{f})\,(s\mathfrak{g}) & \subseteq & R \end{array}$$

Further $\mathfrak{f} : \mathfrak{g}$ is an R-sub-module of F since: if $x, y \in \mathfrak{f} : \mathfrak{g}$ and $a \in R$ then $(ax + y)\mathfrak{g} \subseteq a\mathfrak{f} + \mathfrak{f} = \mathfrak{f}$. Thus it remains to prove that $\mathfrak{f} : \mathfrak{g} \trianglelefteq_{\mathfrak{f}} R$ truly is a fraction ideal. To do this let $r\mathfrak{f} \subseteq R$ and $s\mathfrak{g} \subseteq R$. As $\mathfrak{g} \neq 0$ we may choose some $0 \neq g \in \mathfrak{g}$, then clearly $sg \in \mathfrak{g} \cap R$ and $sg \neq 0$, as R is an integral domain. But now $(rsg)(\mathfrak{f} : \mathfrak{g}) \subseteq R$ as for any $x \in \mathfrak{f} : \mathfrak{g}$ we get$(rsg)x = r(xsg) \in r\mathfrak{f} \subseteq R$. □

Proof of (2.155):
(b) $\Longrightarrow$ (a) is trivial, by choosing $\mathfrak{g} := R : \mathfrak{f}$. Thus consider (a) $\Longrightarrow$ (b): that is we assume $\mathfrak{f}\mathfrak{g} = R$ for some $\mathfrak{g} \trianglelefteq_{\mathfrak{f}} R$. Then by construction we have $\mathfrak{g} \subseteq \{x \in F \mid x\mathfrak{f} \subseteq R\} = R : \mathfrak{f}$. Hence $R = \mathfrak{f}\mathfrak{g} \subseteq \mathfrak{f}(R : \mathfrak{f}) \subseteq R$ (the latter inclusion has been shown in the remark above) which is $R = \mathfrak{f}(R : \mathfrak{f})$. It remains to verify the uniqueness of the inverse $\mathfrak{g}$ - but this is simply due to the associativity of the multiplication. We start with $\mathfrak{f}\mathfrak{g} = R = \mathfrak{f}(R : \mathfrak{f})$. Multiplying (from the left) with $\mathfrak{g}$ yields $\mathfrak{g} = R\mathfrak{g} = (\mathfrak{f}\mathfrak{g})\mathfrak{g} = (\mathfrak{g}\mathfrak{f})\mathfrak{g} = \mathfrak{g}(\mathfrak{f}\mathfrak{g}) = \mathfrak{g}(\mathfrak{f}(R : \mathfrak{f})) = (\mathfrak{g}\mathfrak{f})(R : \mathfrak{f}) = (\mathfrak{f}\mathfrak{g})(R : \mathfrak{f}) = R(R : \mathfrak{f}) = R : \mathfrak{f}$. □

Proof of (2.156):
(a) $\Longrightarrow$ (b): by assumption (a) we've got $1 \in R = \mathfrak{a}\mathfrak{g}$. Hence there are some $a_i \in \mathfrak{a}$ and $x_i \in \mathfrak{g}$ such that $1 = a_1 x_1 + \ldots a_n x_n \in \mathfrak{a}\mathfrak{g}$. And as the x_i are contained in $x_i \in \mathfrak{g} = \mathfrak{a}^{-1} = R : \mathfrak{a}$ we have $x_i\mathfrak{a} \in R$ as claimed. (b) $\Longrightarrow$ (a): conversely suppose we are given such a_i and x_i then by definition $a_i \in \mathfrak{a}$ and $x_i \in R : \mathfrak{a}$. And as $a_1 x_1 + \ldots a_n x_n = 1$ we also we have $R \subseteq \mathfrak{a}(R : \mathfrak{a}) \subseteq R$ and hence $R = \mathfrak{a}(R : \mathfrak{a})$. Thus we next concern ourselves with the implication (b) $\Longrightarrow$ (c): suppose we have chosen some $a_i \in \mathfrak{a}$ and $x_i \in F$ as noted under (b), then we define two R-module homomorphisms

$$\psi \;:\; R^n \to \mathfrak{a} \;:\; (r_1, \ldots, r_n) \mapsto a_1 r_1 + \ldots a_n r_n$$

$$\psi' \;:\; \mathfrak{a} \to R^n \;:\; a \mapsto (ax_1, \ldots, ax_n)$$

Note that the latter is well-defined, since $x_i\mathfrak{a} \subseteq R$ by assumption. But if now $a \in \mathfrak{a}$ is chosen arbitarily

then we get

$$\psi\psi'(a) \;=\; aa_1x_1 + \cdots + aa_nx_n \;=\; a$$

as $a_1x_1 + \cdots + a_nx_n = 1$. This is $\psi\psi' = \mathbb{1}$ on $\mathfrak{a}$. Now regard the following (obviously exact) chain of R-modules

$$0 \longrightarrow \mathrm{kn}(\psi) \xrightarrow{\subseteq} R^n \xrightarrow{\psi} \mathfrak{a} \longrightarrow 0$$

As we have just seen, this chain splits, as $\psi\psi' = \mathbb{1}$ and hence $\mathfrak{a}$ is a direct summand of the free R-module R^n (which in particular means that $\mathfrak{a}$ is projective) by virtue of

$$R^n \;\cong_{\mathrm{m}}\; \mathfrak{a} \oplus \mathrm{kn}(\psi) \;:\; r \mapsto \Big(\psi(r), r - \psi'\psi(r)\Big)$$

Conversely suppose (c), that is $M = \mathfrak{a} \oplus P$, then we need to prove (b). To do this we define the R-module homomorphisms $\varrho : M \twoheadrightarrow \mathfrak{a} : (a,p) \mapsto a$ and $\iota : \mathfrak{a} \hookrightarrow M : a \mapsto (a,0)$. Then clearly $\varrho\,\iota = \mathbb{1}$. As M is free by assumption it has an R-basis $\{\, m_i \mid i \in I \,\}$. And hence any $a \in \mathfrak{a}$ has a representation in the form

$$a \;=\; \varrho\iota(a) \;=\; \varrho\left(\sum_{i\in I} a_i m_i\right) \;=\; \sum_{i\in I} a_i \varrho(m_i)$$

Note that only finitely many of the a_i are non-zero, as these are the coefficients of the basis representation of $\iota(a)$. This representation allows us to define another R-module homomorphism

$$\pi_i \;:\; \mathfrak{a} \to R \;:\; a \mapsto a_i$$

Now consider any two non-zero elements $0 \neq a, b \in \mathfrak{a}$ then we see that $b\pi_i(a) = \pi_i(ba) = \pi_i(ab) = a\pi_i(b)$. And hence we may define an element $x_i \in F$ independently of the choice of $0 \neq a \in \mathfrak{a}$ by letting

$$x_i \;:=\; \frac{\pi_i(a)}{a}$$

Note that only finitely many a_i were non-zero and hence only finitely many x_i are non-zero. The one property is easy to see: if $0 \neq a \in \mathfrak{a}$ is any element then we get $x_i a = \pi_i(a) \in R$ and hence $x_i\mathfrak{a} \subseteq R$. The other property requires only slightly more effort: just compute

$$a \;=\; \sum_{i\in I} \pi_i(a)\varrho(m_i) \;=\; \sum_{i\in I} a x_i \varrho(m_i) \;=\; a\left(\sum_{i\in I} x_i \varrho(m_i)\right)$$

Recall that only finitely many x_i were non-zero and for these let us denote $h_i := \varrho(m_i)$. As a was non-zero we may divide by a to see that $1 = \sum_i x_i h_i$ which was all that remained to prove. □

Proof of (2.157):

- (a) $\Longrightarrow$ (b): as $\mathfrak{a} \neq 0$ is non-zero $a \neq 0$ is non-zero and hence we may choose $\mathfrak{g} := (1/a)R$. Then we clearly get $\mathfrak{a}\,\mathfrak{g} = (aR)(1/aR) = R$.
- (b) $\Longrightarrow$ (a): as $\mathfrak{a}$ is invertible, it is a projective R-module. But R is a local ring and hence any projective R-module already is free. Now $\mathfrak{a}$ being free implies that $\mathfrak{a}$ is a principal ideal (if the basis contained more than one element - say b_1 and b_2 - then $b_2b_1 + (-b_1)b_2 = 0$ would be a non-trivial linear combination).

□

Proof of (2.159):
We will now prove the equivalences in the definition of Dedekind domains. Among other useful statements we will thereby proof (2.161.(i)) already. Note that the order of proofs is somewhat unusual: (d) $\iff$ (e) followed by (e) $\implies$ (a) $\implies$ (b) $\implies$ (c) $\implies$ (b) $\implies$ (d).

- (d) $\implies$ (e): consider any prime ideal $\mathfrak{q} \trianglelefteq_{\mathrm{i}} R$ and let $U := R \setminus \mathfrak{q}$, that is $R_{\mathfrak{q}} = U^{-1}R$. Then $R_{\mathfrak{q}}$ is a local ring by (2.138). And as R was assumed to be normal, so is $R_{\mathfrak{q}}$, by (2.131). And by (2.129) the spectrum of $R_{\mathfrak{q}}$ corresponds to $\{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{p} \subseteq \mathfrak{q} \,\}$. Yet if $\mathfrak{p} \neq 0$, then $\mathfrak{p}$ already is maximal by assumption and hence $\mathfrak{p} = \mathfrak{q}$. Thus we have $\{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{p} \subseteq \mathfrak{q} \,\} = \{\, 0, \mathfrak{q} \,\}$. Thereby $\mathrm{Spec}(R_{\mathfrak{q}})$ has precisely the prime ideals 0 (corresponding to 0 in R) and its maximal ideal (corresponding to $\mathfrak{q}$) in R. Altogether it satisfies condition (f) of DVRs.

- (e) $\implies$ (d): by assumption R is a noetherian integral domain. Thus it remains to prove, that it is normal and satisfies $\mathrm{Spec}(R) = \mathrm{Smax}(R) \cap \{0\}$. By assumption any localization $R_{\mathfrak{p}}$ is a DVR, hence a PID, hence an UFD and hence normal by (2.65). And as R is an integral domain this implies that R itself is normal, too by (2.134). Thus consider any prime ideal $0 \neq \mathfrak{p} \trianglelefteq_{\mathrm{i}} R$. It remains to prove that $\mathfrak{p}$ is maximal. Thus we choose any maximal ideal ideal $\mathfrak{m}$ with $\mathfrak{p} \subseteq \mathfrak{m}$. By assumption $R_{\mathfrak{m}}$ is a DVR, and hence has precisely the prime ideals 0 and $\mathfrak{m}_{\mathfrak{m}}$ (2.147). But as $0 \neq \mathfrak{p} \subseteq \mathfrak{m}$ by (2.129) the localization $\mathfrak{p}_{\mathfrak{m}}$ is a non-zero prime ideal of $R_{\mathfrak{m}}$ and hence $\mathfrak{p}_{\mathfrak{m}} = \mathfrak{m}_{\mathfrak{m}}$. Invoking the correspondence again we find $\mathfrak{p} = \mathfrak{m}$ and hence $\mathfrak{p}$ truly is maximal.

- R DVR $\implies$ (a): let $\mathfrak{m}$ be the maximal ideal of R and m a uniformizing parameter, that is $\mathfrak{m} = mR$. (1) If now $0 \neq \mathfrak{f} \trianglelefteq_{\mathrm{f}} R$ is a non-zero fraction ideal, then $\mathfrak{a} := \mathfrak{f} \cap R \trianglelefteq_{\mathrm{i}} R$ is an ideal of R. And by definition there is some $0 \neq r \in R$ such that $r\mathfrak{f} \subseteq R$. Recall that by (2.146.(iv)) in a DVR $r \in R$ is uniquely represented, as $r = \varrho m^k$ with $\varrho \in R^*$ and $k = \nu(r) \in \mathbb{N}$. Among those $r \in R$ with $r\mathfrak{f} \subseteq R$ we now choose one with minimal $k = \nu(r)$. (2) We first note that $\mathfrak{a} \neq 0$, just choose some $0 \neq x \in \mathfrak{f}$, then $rx \in \mathfrak{a}$ and as $r, x \neq 0$ we also have $rx \neq 0$. Thus by (2.146.(v)) $\mathfrak{a}$ is of the form $\mathfrak{a} = m^n R$ for some $n \in \mathbb{N}$. (3) Now
$$\mathfrak{f} \;=\; m^{n-k} R$$
"$\subseteq$" if $x \in \mathfrak{f}$ then by (2) we have $rx \in \mathfrak{a} = m^n R$, say $rx = m^n p$. Therefore $x = m^n p/r = \varrho^{-1} p m^{n-k} \in m^{n-k}R$. "$\supseteq$" If $k = 0$, then $r = \varrho \in R^*$ is a unit and hence $\mathfrak{f} = r\mathfrak{f} \subseteq R$. Thus we get $\mathfrak{f} = \mathfrak{a} = m^n R = m^{n-k}R$. Now suppose $k \geq 1$, as k has been chosen minimally, there is some $x = a/b \in \mathfrak{f}$ such that $m^{k-1}x \notin R$. That is $b \not| m^{k-1}a$ and hence $\nu(b) > \nu(m^{k-1}a) = k - 1 + \nu(a)$ by the properties of discrete valuations. However $rx \in R$ and hence $b \mid m^k a$. This yields $\nu(b) \leq \nu(am^k) = k + \nu(a)$ altogether $\nu(b) = k + \nu(a)$. Thus if we represent $a = \alpha m^i$ with $\alpha \in R^*$ and $i = \nu(a)$ then $b = \beta m^j$ with $\beta \in R^*$ and $j = \nu(b) = k + i$. Therefore $x = a/b = \alpha\beta^{-1}m^{-k}$ such that $rx = \alpha\varrho\beta^{-1} \in R^*$. On the other hand $rx \in \mathfrak{a} = m^n R$ and hence $\mathfrak{a} = R$, that is $n = 0$. Thus $m^{-k} = \beta\alpha^{-1}x \in \mathfrak{f}$ such that $m^{n-k}R = m^{-k}R \subseteq \mathfrak{f}$. This settles the proof of the equality (3). But now we have seen, that $\mathfrak{f} = m^{n-k}R$ is a principal ideal, in particular it is invertible, with inverse $\mathfrak{f}^{-1} = m^{k-n}R$.

- (e) $\implies$ (a): if R is a field, then $\mathfrak{f} = R$ is the one and only non-zero fraction ideal of R. And $\mathfrak{f} = R$ trivially is invertible, with inverse $\mathfrak{f}^{-1} = R$. Thus in the following we assume that R is not

a field, then we choose any non-zero prime ideal $0 \neq \mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ in R and let $U := R \setminus \mathfrak{p}$. That is $U^{-1}R = R_{\mathfrak{p}}$ and by assumption $R_{\mathfrak{p}}$ is a DVR. Thus consider a non-zero fraction ideal $0 \neq \mathfrak{f} \trianglelefteq_{\mathrm{f}} R$, then $0 \neq U^{-1}\mathfrak{f} \trianglelefteq_{\mathrm{f}} R_{\mathfrak{p}}$ is a fraction ideal of $R_{\mathfrak{p}}$. But as we have just seen this implies, that $U^{-1}R$ is invertible (regarding $R_{\mathfrak{p}}$). But by the remarks in section 2.12 this already yields that $\mathfrak{f}$ is invertible (regarding R).

- (a) $\implies$ (b) is trivial, so we will now prove (b) $\implies$ (c): by assumption (b) any non-zero ideal is invertible and hence finitely generated (by the remarks in section 2.12). And as 0 trivially is finitely generated R is a noetherian ring. Now consider any non-trivial ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$, that is $\mathfrak{a} \notin \{0, R\}$ and let $\mathfrak{a}_0 := \mathfrak{a}$. As $\mathfrak{a} \neq R$ we may choose some prime ideal $\mathfrak{p}_1 \in \operatorname{Spec}(R)$ containing $\mathfrak{a} \subseteq \mathfrak{p}_1$, by (2.4.(ii)). Now let

$$\mathfrak{a}_1 \;:=\; \mathfrak{a}_0(\mathfrak{p}_1)^{-1} \;=\; \mathfrak{a}_0(R:\mathfrak{p}_1) \;\subseteq\; \mathfrak{a}_0(R:\mathfrak{a}_0) \;=\; R$$

 Here the inclusion $R:\mathfrak{p}_1 \subseteq R:\mathfrak{a}_0$ holds because of $\mathfrak{a}_0 \subseteq \mathfrak{p}_1$ and $\mathfrak{a}_0(R:\mathfrak{a}_0) = R$ is true because $\mathfrak{a}_0$ is invertible by assumption (a). Hence $\mathfrak{a}_1 \trianglelefteq_{\mathrm{i}} R$ is an ideal of R and by construction

$$\mathfrak{a} \;=\; \mathfrak{a}_0 \;=\; \mathfrak{p}_1\mathfrak{a}_1$$

 We will now construct an ascending chain $\mathfrak{a} = \mathfrak{a}_0 \subseteq \mathfrak{a}_1 \subseteq \ldots \subseteq \mathfrak{a}_n \ldots$ of ideals of R. Suppose we have already constructed $\mathfrak{a}_k \trianglelefteq_{\mathrm{i}} R$ and the prime ideals $\mathfrak{p}_1, \ldots, \mathfrak{p}_k \in \operatorname{Spec}(R)$ such that $\mathfrak{a} = \mathfrak{p}_1 \ldots \mathfrak{p}_k\mathfrak{a}_k$. If $\mathfrak{a}_k = R$ then we are done as we have already decomposed $\mathfrak{a} = \mathfrak{p}_1 \ldots \mathfrak{p}_k$ in this case. Thus assume $\mathfrak{a}_k \neq R$. Then we may choose any prime ideal $\mathfrak{p}_{k+1}$ containing $\mathfrak{a}_k \subseteq \mathfrak{p}_{k+1}$ again. As for the case $k = 1$ above, we let $\mathfrak{a}_{k+1} := \mathfrak{a}_k(\mathfrak{p}_{k+1})^{-1}$ and find that $\mathfrak{a}_{k+1} \trianglelefteq_{\mathrm{i}} R$ is an ideal of R. Then by construction we get

$$\mathfrak{a} \;=\; \mathfrak{p}_1 \ldots \mathfrak{p}_k\,\mathfrak{a}_k \;=\; \mathfrak{p}_1 \ldots \mathfrak{p}_k\,\mathfrak{p}_{k+1}\,\mathfrak{a}_{k+1}$$

 As R is noetherian this chain stabilizes at some point $\mathfrak{a}_n = \mathfrak{a}_{n+1}$ and by construction this means $\mathfrak{a}_{n+1} = \mathfrak{a}_n = \mathfrak{p}_{n+1}\mathfrak{a}_{n+1}$. As $\mathfrak{a}_{n+1}$ is a finitely generated R-module the lemma of Dedekind implies that there is some $p \in \mathfrak{p}_{n+1}$ such that $(1-p)\mathfrak{a}_{n+1} = 0$. But as R is an integral domain and $\mathfrak{a}_{n+1} \neq 0$ this means that $p = 1$, which is absurd, since $\mathfrak{p}_{n+1} \neq R$ is prime. Thus the construction fails at this stage, which can only be if $\mathfrak{a}_n = R$. And as we have mentioned already this is $\mathfrak{a} = \mathfrak{p}_1 \ldots \mathfrak{p}_n$.

- (b) $\implies$ (2.161.(i)): the existence of the factorisation of non-trivial ideals into prime non-zero ideals has been shown in (b) $\implies$ (c) already. Hence it only remains to show that the factorisation is unique up to permutations. Thus assume $\mathfrak{p}_1 \ldots \mathfrak{p}_m = \mathfrak{q}_1 \ldots \mathfrak{q}_n$ where $0 \neq \mathfrak{p}_i$ and $\mathfrak{q}_j \trianglelefteq_{\mathrm{i}} R$ are non-zero prime ideals. Whithout loss of generality we assume $m \leq n$ and use induction on n. The case $m = 1 = n$ is trivial so we are only concerned with the induction step: by renumbering we may assume that $\mathfrak{q}_1$ is minimal among $\{\mathfrak{q}_1, \ldots, \mathfrak{q}_n\}$. And as

$$\mathfrak{p}_1 \ldots \mathfrak{p}_m \;\subseteq\; \bigcap_{i=1}^{m} \mathfrak{p}_i \;\subseteq\; \mathfrak{q}_1$$

 and $\mathfrak{q}_1$ is prime (2.14.(ii)) implies that there is some $i \in 1 \ldots m$ such that $\mathfrak{p}_i \subseteq \mathfrak{q}_1$. Now conversely

as $\mathfrak{p}_i$ is prime and $\mathfrak{q}_1 \dots \mathfrak{q}_n \subseteq \mathfrak{p}_i$ there is some $j \in 1 \dots n$ such that $\mathfrak{q}_j \subseteq \mathfrak{p}_i \subseteq \mathfrak{q}_1$. By minimality of $\mathfrak{q}_1$ this means $\mathfrak{q}_j = \mathfrak{q}_1$ and hence $\mathfrak{p}_i = \mathfrak{q}_1$. By renumbering we may assume $i = 1$. Then multiplying by $\mathfrak{p}_1^{-1} = \mathfrak{q}_1^{-1}$ yields $\mathfrak{p}_2 \dots \mathfrak{p}_m = \mathfrak{q}_2 \dots \mathfrak{q}_n$ so we are done by the induction hypothesis.

- (c) $\implies$ any invertible prime ideal is maximal. Thus consider some invertible prime ideal $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$, in particular $\mathfrak{p} \neq 0$. We will show that for any $u \in R \setminus \mathfrak{p}$ we get $\mathfrak{p} + uR = R$. Suppose we had $\mathfrak{p} + uR \neq R$ then by (b) we could decompose $\mathfrak{p} + uR = \mathfrak{p}_1 \dots \mathfrak{p}_m$ for some prime ideals $\mathfrak{p}_i \trianglelefteq_{\mathfrak{i}} R$. Now take to the quotient ring $R/\mathfrak{p}$, then by (1.66)

$$0 \neq (u+\mathfrak{p})^R\big/_{\mathfrak{p}} = \mathfrak{p}+uR\big/_{\mathfrak{p}} = \mathfrak{p}_1\big/_{\mathfrak{p}} \dots \mathfrak{p}_m\big/_{\mathfrak{p}}$$

But $(u+\mathfrak{p})(R/\mathfrak{p})$, being a principal ideal, is invertible. In particular any of its factors $\mathfrak{p}_i/\mathfrak{p}$ is invertible with inverse given to be

$$\left(\mathfrak{p}_i\big/_{\mathfrak{p}}\right)^{-1} = \left(\frac{1}{u+\mathfrak{p}}\, R\big/_{\mathfrak{p}}\right)\left(\prod_{i\neq j}\mathfrak{p}_j\big/_{\mathfrak{p}}\right)$$

Now we open up a second line of argumentation: we decompose the ideal $\mathfrak{p} + u^2R = \mathfrak{q}_1 \dots \mathfrak{q}_n$ and take to the quotient ring again

$$0 \neq (u^2+\mathfrak{p})^R\big/_{\mathfrak{p}} = \mathfrak{p}+u^2R\big/_{\mathfrak{p}} = \mathfrak{q}_1\big/_{\mathfrak{p}} \dots \mathfrak{q}_n\big/_{\mathfrak{p}}$$

As $((u+\mathfrak{p})R/\mathfrak{p})^2 = (u^2+\mathfrak{p})R/\mathfrak{p}$ we have found two decompositions of $(u^2+\mathfrak{p})R/\mathfrak{p}$ into prime ideals - to be precise we found

$$\left(\mathfrak{p}_1\big/_{\mathfrak{p}}\right)^2 \dots \left(\mathfrak{p}_m\big/_{\mathfrak{p}}\right)^2 = \mathfrak{q}_1\big/_{\mathfrak{p}} \dots \mathfrak{q}_n\big/_{\mathfrak{p}}$$

$R/\mathfrak{p}$ also satisfies the assumption (c) because of the correspondence theorem and as any $\mathfrak{p}_i/\mathfrak{p}$ is invertible the decomposition is unique up to permutations - note that these truly are the only assumptions that were used in the proof of (iii). Hence (by the uniqueness) we get $2m = n$ and $(\mathfrak{p}_1/\mathfrak{p}, \mathfrak{p}_1/\mathfrak{p}, \dots, \mathfrak{p}_m/\mathfrak{p}, \mathfrak{p}_m/\mathfrak{p}) \longleftrightarrow (\mathfrak{q}_1/\mathfrak{p}, \dots, \mathfrak{q}_n/\mathfrak{p})$. But by the correspondence theorem (1.66) again we can return to the original ring R getting $(\mathfrak{p}_1, \mathfrak{p}_1 \dots, \mathfrak{p}_m, \mathfrak{p}_m) \longleftrightarrow (\mathfrak{q}_1, \dots, \mathfrak{q}_n)$. Therefore

$$\begin{aligned} \mathfrak{p} + u^2R &= \mathfrak{q}_1 \dots \mathfrak{q}_n \\ &= \mathfrak{p}_1\mathfrak{p}_1 \dots \mathfrak{p}_m\mathfrak{p}_m \\ &= (\mathfrak{p}+uR)^2 \\ &= \mathfrak{p}^2 + u\mathfrak{p} + u^2R \end{aligned}$$

Hence $\mathfrak{p} \subseteq \mathfrak{p} + u^2R = \mathfrak{p}^2 + u(\mathfrak{p}+uR) \subseteq \mathfrak{p}^2 + uR$. Thus any $p \in \mathfrak{p}$ has a representation as $p = a + ub$ where $a \in \mathfrak{p}^2$ and $b \in R$. Thus $ub = p - a \in \mathfrak{p}$ such that $b \in \mathfrak{p}$. This is $p = a + ub \in \mathfrak{p}^2 + u\mathfrak{p}$ and as p has been arbitrary $\mathfrak{p} \subseteq \mathfrak{p}^2 + u\mathfrak{p} = \mathfrak{p}(\mathfrak{p}+uR)$. Multiplying with $\mathfrak{p}^{-1}$ this is $R \subseteq \mathfrak{p} + uR$ and hence finally $\mathfrak{p} + uR = R$.

- (c) $\implies$ (b): we will first show that non-zero prime ideals $0 \neq \mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ are invertible. To do this choose some $0 \neq a \in \mathfrak{p}$ and decompose $aR = \mathfrak{p}_1 \dots \mathfrak{p}_n$. As aR is invertible - with inverse

$(aR)^{-1} = (1/a)R$ - any $\mathfrak{p}_i$ is invertible, as its inverse is just

$$\left(\mathfrak{p}_i\right)^{-1} \;=\; \frac{1}{a}R \prod_{i\neq j} \mathfrak{p}_j$$

As $\mathfrak{p}$ is prime and $\mathfrak{p}_1 \ldots \mathfrak{p}_n = aR \subseteq \mathfrak{p}$ there is some $i \in 1 \ldots n$ such that $\mathfrak{p}_i \subseteq \mathfrak{p}$. But $\mathfrak{p}_i$ is invertible and hence maximal (see above) such that $\mathfrak{p}_i = \mathfrak{p}$. Thus $\mathfrak{p}$ is invertible. If now $0 \neq \mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ is any non-zero ideal then we decompose $\mathfrak{a} = \mathfrak{p}_1 \ldots \mathfrak{p}_n$ and as any $\mathfrak{p}_i$ is now known to be irreducible we have $\mathfrak{a}^{-1} = \mathfrak{p}_1^{-1} \ldots \mathfrak{p}_n^{-1}$ invertible.

- (b) $\iff$ (c) and (b) $\implies \mathrm{Spec}(R) = \mathrm{Smax}(R) \cup \{0\}$. We have just established the equivalence (b) $\iff$ (c). And we have seen above that (because of (c)) any invertible prime ideal is maximal. But because of (b) *any* non-zero prime ideal already is invertible and hence maximal.

- (b) $\implies$ (d): we have already seen - in (b) $\implies$ (c) - that R is noetherian and that $\mathrm{Spec}(R) = \mathrm{Smax}(R) \cup \{0\}$. Thus it only remains to show that R is normal. If R is a field already then there is nothing to prove, else let $F := \mathrm{QUOT}(R)$ and regard $x = a/b \in F$. If x is integral over R then $R[x]$ is an R-module of finite rank $k+1 := \mathrm{rank}R[x]$. Let now $r := b^k$ - as any element of $R[x]$ is of the form $a_k x^k + \cdots + a_1 x + a_0$ (for some $a_i \in R$) we clearly have $rR[x] \subseteq R$ (in particular $R[x] \trianglelefteq_{\mathfrak{f}} R$ is a fraction ideal of R). And hence for any $n \in \mathbb{N}$ we have $s_n := rx^n \in R$. For any prime ideal $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ let us now denote by $\nu_{\mathfrak{p}}(\mathfrak{a})$ the multiplicity of $\mathfrak{p}$ in the primary decomposition of $\mathfrak{a}$, i.e. we let

$$\nu_{\mathfrak{p}}(\mathfrak{p}_1 \ldots \mathfrak{p}_m) \;:=\; \#\{\, i \in 1 \ldots m \mid \mathfrak{p} = \mathfrak{p}_i \,\} \;\in\; \mathbb{N}$$

Then clearly $\nu_{\mathfrak{p}}$ turns the multiplication of ideals into an addition of multiplicities and hence $ra^n = s_n b^n$ turns into

$$\nu_{\mathfrak{p}}(rR) + n\nu_{\mathfrak{p}}(aR) \;=\; \nu_{\mathfrak{p}}(s_n R) + n\nu_{\mathfrak{p}}(bR)$$

Hence for any $n \in \mathbb{N}$ and any prime ideal $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ we get the estimate

$$\nu_{\mathfrak{p}}(rR) + n(\nu_{\mathfrak{p}}(aR) - \nu_{\mathfrak{p}}(bR)) \;\geq\; \nu_{\mathfrak{p}}(s_n R) \;\geq\; 0$$

By choosing $n > \nu_{\mathfrak{p}}(rR)$ this implies that for any prime ideal $\mathfrak{p}$ we have $\nu_{\mathfrak{p}}(bR) \leq \nu_{\mathfrak{p}}(aR)$. Writing down decompositions of aR and bR we hence find that $aR \subseteq bR$. But this is $b \mid a$ or in other words $x \in R$ which had to be shown.

□

Proof of (2.163):
The proof of the equivalences in the definition (2.162) and the properties (2.163) of valuations of ideals in Dedekind domains is interwoven tightly. Thus we do not attempt to give separate proofs, but verify the properties and equivalences simultaneously.

- $\mathfrak{b} \mid \mathfrak{a} \iff \mathfrak{a} \subseteq \mathfrak{b}$: if $\mathfrak{a} = \mathfrak{b}\,\mathfrak{c}$, then $\mathfrak{b} \subseteq \mathfrak{a}$ is clear. Conversely suppose we had $\mathfrak{a} \subseteq \mathfrak{b}$. If additionally $\mathfrak{b} = 0$ then $\mathfrak{a} = 0$, too and hence we may already take $\mathfrak{c} := R$. Thus suppose $\mathfrak{b} \neq 0$ and let $\mathfrak{c} := \mathfrak{b}^{-1}\mathfrak{a} \trianglelefteq_{\mathfrak{f}} R$. Then $\mathfrak{c} \subseteq \mathfrak{b}^{-1}\mathfrak{b} = R$ and hence $\mathfrak{c} = \mathfrak{c} \cap R \trianglelefteq_{\mathfrak{i}} R$. But on the other hand $\mathfrak{b}\,\mathfrak{c} = \mathfrak{b}\,\mathfrak{b}^{-1}\mathfrak{a} = \mathfrak{a}$ is clear, such that $\mathfrak{b} \mid \mathfrak{a}$.

(i) In case $\mathfrak{m} \notin \mathcal{M}$ we may pick up $\mathfrak{m}_0 := \mathfrak{m}$ and $k(0) := 0$ reducing this to to the case $\mathfrak{m} \in \mathcal{M}$. And if $\mathfrak{m} \in \mathcal{M}$ then by renumbering we may assume that $\mathfrak{m} = \mathfrak{m}_1$. Thus regard $\mathfrak{a} := \mathfrak{m}_1^{k(1)} \dots \mathfrak{m}_n^{k(n)}$, then $\mathfrak{a} \subseteq \mathfrak{m}^{k(1)}$ is clear and hence $\nu_{\mathfrak{m}}(\mathfrak{a}) \geq k(1)$, by definition of $\nu_{\mathfrak{m}}$. Thus assume $\nu_{\mathfrak{m}} > k(1)$, this means $\mathfrak{a} \subseteq \mathfrak{m}^{k(1)+1}$ and by what we have just shown there is some $\mathfrak{c} \trianglelefteq_{\mathfrak{i}} R$ such that $\mathfrak{a} = \mathfrak{m}^{k(1)+1}\mathfrak{c}$. Therefore

$$\mathfrak{m}_1^{k(2)} \dots \mathfrak{m}_n^{k(n)} \;=\; \mathfrak{m}^{-k(1)}\mathfrak{a} \;=\; \mathfrak{m}\,\mathfrak{c} \;\subseteq\; \mathfrak{m}$$

But as $\mathfrak{m}$ is prime this means that there is some $i \in 2 \dots n$ such that $\mathfrak{m}_i^{k(i)} \subseteq \mathfrak{m}$. Clearly $k(i) \neq 0$ as else $R \subseteq \mathfrak{m}$ and hence $\mathfrak{m}_i \subseteq \mathfrak{m}$ by the same argument. But $\mathfrak{m}_i$ has been maximal and hence $\mathfrak{m}_i = \mathfrak{m} = \mathfrak{m}_1$ in contradiction to the $\mathfrak{m}_i$ being pairwise distinct.

(ii) Decompose $\mathfrak{a} = \mathfrak{m}_1^{k(1)} \dots \mathfrak{m}_n^{k(n)}$ and $\mathfrak{b} = \mathfrak{m}_1^{l(1)} \dots \mathfrak{m}_n^{l(n)}$ as in the formulation of (iii). Also as in the proof of (i) we may also assume that $\mathfrak{m} = \mathfrak{m}_1$ (by picking up $\mathfrak{m}_0 := \mathfrak{m}$, $k(0) := 0$ and $l(0) := 0$ if necessary and renumbering). Then it is clear that $\mathfrak{a}\,\mathfrak{b} = \mathfrak{m}_1^{k(1)+l()} \dots \mathfrak{m}_n^{k(n)+l(n)}$. And using (i) the claim follows readily: $\nu_{\mathfrak{m}}(\mathfrak{a}\,\mathfrak{b}) = k(1) + l(1) = \nu_{\mathfrak{m}}(\mathfrak{a}) + \nu_{\mathfrak{m}}(\mathfrak{b})$.

- $\mathfrak{a} \mid \mathfrak{b} \iff \forall\, \mathfrak{m} : \nu_{\mathfrak{m}}(\mathfrak{b}) \leq \nu_{\mathfrak{m}}(\mathfrak{a})$. Clearly if $\mathfrak{a} = \mathfrak{b}\,\mathfrak{c}$ then by (ii) we get $\nu_{\mathfrak{m}}(\mathfrak{a}) = \nu_{\mathfrak{m}}(\mathfrak{b}) + \nu_{\mathfrak{m}}(\mathfrak{b}) \geq \nu_{\mathfrak{m}}(\mathfrak{b})$. Conversely decompose $\mathfrak{a} = \mathfrak{m}_1^{k(1)} \dots \mathfrak{m}_n^{k(n)}$ and $\mathfrak{b} = \mathfrak{m}_1^{l(1)} \dots \mathfrak{m}_n^{l(n)}$ once more. By (i) that is $k(i) = \nu_{\mathfrak{m}_i}(\mathfrak{a})$ and $l(i) = \nu_{\mathfrak{m}_i}(\mathfrak{b})$. Thus by assumption we have $l(i) \leq k(i)$ and may hence define $\mathfrak{c} = \mathfrak{m}_1^{k(1)-l(1)} \dots \mathfrak{m}_n^{k(n)-l(1)} \trianglelefteq_{\mathfrak{i}} R$. Then by construction we immediately get $\mathfrak{b}\,\mathfrak{c} = \mathfrak{a}$.

(iii) First let $m(\mathfrak{m}) := \min\{\, \nu_{\mathfrak{m}}(\mathfrak{a}), \nu_{\mathfrak{m}}(\mathfrak{b}) \,\}$ for any $\mathfrak{m} \in \mathrm{Smax}(R)$. Note that for $\mathfrak{m} = \mathfrak{m}_i$ we in particular get $m(\mathfrak{m}) = m(i)$ and if $\mathfrak{m}$ is not contained in the $\mathfrak{m}_i$ then $m(\mathfrak{m}) = 0$. And therefore we get

$$\mathfrak{m}_1^{m(1)} \dots \mathfrak{m}_n^{m(n)} \;=\; \prod_{\mathfrak{m}} \mathfrak{m}^{m(\mathfrak{m})}$$

Now consider any ideal $\mathfrak{c} \trianglelefteq_{\mathfrak{i}} R$, then by the equivalences we have already proved for $\mathfrak{a} \mid \mathfrak{b}$ it is evident that we obtain the following chain of equivalent statements

$$\begin{aligned}
& \forall\, \mathfrak{m} \;:\; \nu_{\mathfrak{m}}(\mathfrak{c}) \leq \nu_{\mathfrak{m}}(\mathfrak{a}+\mathfrak{b}) \\
\iff\; & \mathfrak{a}+\mathfrak{b} \;\subseteq\; \mathfrak{c} \\
\iff\; & \mathfrak{a} \subseteq \mathfrak{c} \text{ and } \mathfrak{b} \subseteq \mathfrak{c} \\
\iff\; & \forall\, \mathfrak{m} \;:\; \nu_{\mathfrak{m}}(\mathfrak{c}) \leq \nu_{\mathfrak{m}}(\mathfrak{a}) \quad \text{and} \quad \nu_{\mathfrak{m}}(\mathfrak{c}) \leq \nu_{\mathfrak{m}}(\mathfrak{b}) \\
\iff\; & \forall\, \mathfrak{m} \;:\; \nu_{\mathfrak{m}}(\mathfrak{c}) \leq m(\mathfrak{m})
\end{aligned}$$

Thus for a fixed $\mathfrak{m} \in \mathrm{Smax}(R)$ we may regard $\mathfrak{c} := \mathfrak{m}^j$. And by (i) this satisfies $\nu_{\mathfrak{m}}(\mathfrak{c}) = j$, that is we may take $\nu_{\mathfrak{m}}(\mathfrak{c})$ to be any $j \in \mathbb{N}$ of our liking. And therefore the above equivalence immediately yields $\nu_{\mathfrak{m}}(\mathfrak{a}+\mathfrak{b}) = m(\mathfrak{m})$ and hence the equality for $\mathfrak{a}+\mathfrak{b}$ claimed.

(iv) Consider any two non-zero ideals $\mathfrak{a}$, $\mathfrak{b}$ of R, then by (iii) $\mathfrak{a}$ and $\mathfrak{b}$ are coprime (i.e. $\mathfrak{a}+\mathfrak{b} = R$) if and only if for any $\mathfrak{m} \in \mathrm{Smax}(R)$ we get $\nu_{\mathfrak{m}}(\mathfrak{a}) = 0$ or $\nu_{\mathfrak{m}}(\mathfrak{b}) = 0$. In particular for any $\mathfrak{m} \neq \mathfrak{m} \in \mathrm{Smax}(R)$ and any k, $l \in \mathbb{N}$ we see that $\mathfrak{m}^k$ and $\mathfrak{n}^l$ are coprime. Thus the claim follows immediately from the original Chinese remainder theorem (1.99).

(v) If $\mathfrak{a} = aR$ is a principal ideal, then we may take $\mathfrak{b} := R$, then $\mathfrak{a}+\mathfrak{b} = R$ and $\mathfrak{a}\,\mathfrak{b} = \mathfrak{a} = aR$ are satisfied trivially. Thus suppose $\mathfrak{a}$ is no principal ideal (in particular $\mathfrak{a} \neq 0$), then we may

decompose $\mathfrak{a} = \mathfrak{m}_1^{k(1)} \dots \mathfrak{m}_n^{k(n)}$ as usual. Now for any $i \in 1 \dots n$ pick up some $b_i \in R$ such that $b_i \in \mathfrak{m}_i^{k(i)}$ but $b_i \notin \mathfrak{m}_i^{k(i)+1}$ (thereby $\mathfrak{m}_i^{k(i)} \setminus \mathfrak{m}_i^{k(i)+1} \neq \emptyset$ is non-empty, as we else had $R = \mathfrak{m}_i$ by multiplication with $\mathfrak{m}_i^{-k(i)}$). Hence by (iv) there is some $b \in R$ that is mapped to $(b_i \in \mathfrak{m}_i^{k(i)+1})$ under the isomorphism of the Chinese remainder theorem. That is for any $i \in 1 \dots n$ we have $b + \mathfrak{m}_i^{k(i)+1} = b_i + \mathfrak{m}_i^{k(i)+1}$. In particular we find $b \in \mathfrak{m}_i^{k(i)}$ and $b \notin \mathfrak{m}_i^{k(i)+1}$ again. This is to say that $\nu_{\mathfrak{m}_i}(b) = k_i$ for any $i \in 1 \dots n$. That is if we decompose bR then there are some $n \leq N \in \mathbb{N}$, $\mathfrak{m}_i \in \mathrm{Smax}(R)$ and $1 \leq k(i) \in \mathbb{N}$ (where $i \in n+1 \dots N$) such that

$$bR \;=\; \prod_{\mathfrak{m}} \mathfrak{m}^{k(\mathfrak{m})} \;=\; \prod_{i=1}^{N} \mathfrak{m}_i^{k(i)}$$

Note that $n < N$, if we had $n = N$ then $bR = \mathfrak{a}$ already would be a principal ideal, which had been dealt with already. Thus if we let $\mathfrak{b} := \mathfrak{m}_{n+1}^{k(n+1)} \dots \mathfrak{m}_N^{k(N)}$, then it is evident, that $\mathfrak{a}\,\mathfrak{b} = bR$ is principal. But also by construction $\mathfrak{a}$ and $\mathfrak{b}$ satisfy $\nu_{\mathfrak{m}}(\mathfrak{a}) = 0$ or $\nu_{\mathfrak{m}}(\mathfrak{b}) = 0$ for any $\mathfrak{m} \in \mathrm{Smax}(R)$. And as we have already argued in (iv) this is $\mathfrak{a} + \mathfrak{b} = R$.

□

Proof of (2.161):
Note that (i) and (ii) have already been shown while proving the equivalences in the definition of Dedekind domains on page 1111. Thus it only remains to verify (iii) to (vi), which we will do now:

(vi) Let us denote the mapping (of course we still have to check the well-definedness) given by Φ, that is $\Phi(a + \mathfrak{m}^k) := a/1 + \mathfrak{m}^k R_{\mathfrak{m}}$. Now consider any a, $b \in R$ and u, $v \notin \mathfrak{m}$, then in a first step, we will prove

$$\frac{a}{u} + \mathfrak{m}^k R_{\mathfrak{m}} + \frac{b}{v} + \mathfrak{m}^k R_{\mathfrak{m}} \quad\Longleftrightarrow\quad av - bu \in \mathfrak{m}^k$$

If $av - bu \in \mathfrak{m}^k$ then (as $uv \notin \mathfrak{m}$) it is clear, that $(a/u) - (b/v) = (av - bu)/uv \in \mathfrak{m}^k R_{\mathfrak{m}}$. And thereby also $a/u + \mathfrak{m}^k R_{\mathfrak{m}} + b/v + \mathfrak{m}^k R_{\mathfrak{m}}$. Conversely let us assume $(av - bu)/uv = (a/u) - (b/v) \in \mathfrak{m}^k R_{\mathfrak{m}}$. That is there are some $m \in \mathfrak{m}^k$ and $w \notin \mathfrak{m}$ such that $(av - bu)/uv = m/w$ and hence $w(av - bu) = muv \in \mathfrak{m}^k$. Therefore $w(av - bu)R \subseteq \mathfrak{m}^k$ such that by (2.162) and (2.163)

$$k \;=\; \nu_{\mathfrak{m}}(\mathfrak{m}^k) \;\leq\; \nu_{\mathfrak{m}}(w(av - bu)) \;=\; \nu_{\mathfrak{m}}(w) + \nu_{\mathfrak{m}}(av - bu)$$

Yet $w \notin \mathfrak{m}$ and hence $\nu_{\mathfrak{m}}(w) = 0$. Therefore we get $\nu_{\mathfrak{m}}(av - bu) = k$ and this translates into $av - bu \in \mathfrak{m}^k$ as claimed. And this immediately yields the equivalences: $a + \mathfrak{m}^k = b + \mathfrak{m}^k$ iff $a - b \in \mathfrak{m}^k$ iff $\Phi(a + \mathfrak{m}^k) = \Phi(b + \mathfrak{m}^k)$. And this has been the well-definedness and injectivity of Φ. Thus it remains to prove the surjectivity of Φ: we are given any $a/u + \mathfrak{m}^k R_{\mathfrak{m}}$ and need to find some $b \in R$ such that $a/u + \mathfrak{m}^k R_{\mathfrak{m}} = b/1 + \mathfrak{m}^k R_{\mathfrak{m}}$. Yet $u \notin \mathfrak{m}$ and $\mathfrak{m}$ is a maximal ideal, that is $R/\mathfrak{m}$ is a field and hence there is some $v \notin \mathfrak{m}$ such that $v + \mathfrak{m} = (u + \mathfrak{m})^{-1}$. That is $1 - uv \in \mathfrak{m}$ and in particular $(1 - uv)^k \in \mathfrak{m}^k$. But by the binomial rule we may compute

$$\begin{aligned}(1 - uv)^k \;&=\; (-1)^k (uv - 1)^k \;=\; (-1)^k \sum_{i=0}^{k} \binom{k}{i} (uv)^i (-1)^{k-i} \\ &=\; \sum_{i=0}^{k} (-1)^i \binom{k}{i} (uv)^i \;=\; 1 + u \sum_{i=1}^{k} (-1)^i \binom{k}{i} u^{i-1} v^i\end{aligned}$$

That is we get $(1-uv)^k = 1+uq$ for some adequately chosen $q \in R$. Then we define $b := -aq$, now an easy computation yields $a - bu = a(1+uq) = a(1-uv)^k \in \mathfrak{m}^k$. Thus by the above equivalence we find $\Phi(b+\mathfrak{m}^k) = a/u + \mathfrak{m}^k R_\mathfrak{m}$.

(iii) (1) Let us first assume, that $\mathfrak{a} = \mathfrak{m}^k$ is a power of a maximal ideal $\mathfrak{m} \trianglelefteq_\mathrm{i} R$. If $k = 0$, then $\mathfrak{a} = R$ such that $R/\mathfrak{a} = 0$ such that we have nothing to prove. Thus assume $k \geq 1$, then by (vi) $R/\mathfrak{a}$ is isomorphic to $R_\mathfrak{m}/\mathfrak{a}R_\mathfrak{m}$. But as R is a Dedekind domain $R_\mathfrak{m}$ is a DVR (by (2.159.(e))) and in particular a PID (by (2.147.(c))). Therefore the quotient $R_\mathfrak{m}/\mathfrak{a}R_\mathfrak{m}$ is a principal ring (see section 2.7). Thus the isomorphy shows, that $R/\mathfrak{a}$ is a principal ring. (2) Now consider any $0 \neq \mathfrak{a} \trianglelefteq_\mathrm{i} R$. We have already dealt with the case $\mathfrak{a} = R$ in (1).($k = 0$). Thus suppose $\mathfrak{a} \neq R$ and decompose $\mathfrak{a} = \mathfrak{m}_1^{k(1)} \dots \mathfrak{m}_n^{k(n)}$ (with $n(i) \geq 1$). Then by the Chinese remainder theorem in (2.163)

$$R \Big/ \mathfrak{a} \quad \cong_\mathrm{r} \quad R \Big/ \mathfrak{m}_1^{k(1)} \oplus \dots \oplus R \Big/ \mathfrak{m}_n^{k(n)}$$

Now every $R/\mathfrak{m}_i^{k(i)}$ is a principal ring due to case (1). But the direct sum of principal rings is a principal again, due to the some remark in section 2.7. Thus the isomorphy shows, that $R/\mathfrak{a}$ is a principal ring.

(iv) Consider any $\mathfrak{a} \trianglelefteq_\mathrm{i} R$ and $0 \neq a \in R$, then by (iii) R/aR is a principal ring and hence $\mathfrak{a}/aR$ is a principal ideal - say $\mathfrak{a}/aR = (b+aR)(R/aR)$ for some $b \in R$. As $b + aR \in \mathfrak{a}/aR$ it is clear that $b \in \mathfrak{a}$, in particular $aR + bR \subseteq \mathfrak{a}$. Now consider any $c \in \mathfrak{a}$, then $c + aR \in \mathfrak{a}/aR = (b+aR)(R/aR)$. That is there is some $v \in R$ such that $c + aR = (b+aR)(v+aR) = bv + aR$. Hence $c - bv \in aR$ which means that $c - bv = au$ for some $u \in R$. And as $c = au + bv \in \mathfrak{a}$ has been arbitrary this also is $\mathfrak{a} \subseteq aR + bR$

(v) Let us denote the set of all prime ideals that are not principal by $\mathcal{P}$ - formally $\mathcal{P} := \{ \mathfrak{p} \in \mathrm{Spec}(R) \mid \nexists p \in R : \mathfrak{p} =$ (1) clearly $n := \#\mathcal{P} < \infty$, as $\mathcal{P} \subseteq \mathrm{Spec}(R) \setminus \{0\} = \mathrm{Smax}(R)$ and the maximal spectrum of R is finite by assumption. If we have $n = 0$ then any prime ideal is principal. Thus if $\mathfrak{a} \trianglelefteq_\mathrm{i} R$ is any ideal decompose $\mathfrak{a} = \mathfrak{p}_1 \dots \mathfrak{p}_k$ where $\mathfrak{p}_i \trianglelefteq_\mathrm{i} R$ is prime (using (c)). Then $\mathfrak{p}_i = p_i R$ is principal and hence $\mathfrak{a} = aR$ is principal, too by letting $a := p_1 \dots p_k$. Thus it suffices to assume $n \geq 1$ and to derive a contradiction. (2) Let us denote $\mathfrak{b} := \mathfrak{p}_1 \dots \mathfrak{p}_n$ and $\mathfrak{a} := \mathfrak{p}_1 \mathfrak{b} = \mathfrak{p}_1^2 \mathfrak{p}_2 \dots \mathfrak{p}_n$. Then $\mathfrak{a} \neq \mathfrak{b}$, as else $R = \mathfrak{b}\,\mathfrak{b}^{-1} = \mathfrak{a}\,\mathfrak{b}^{-1} = \mathfrak{p}_1$ - a contradiction (recall that $\mathfrak{b} \neq 0$, as R is an integral domain and hence we may apply (b)). (3) Next we claim that there is some $u \in \mathfrak{p}_1$ such that $u \notin \mathfrak{p}_1^2$, $u \notin \mathfrak{p}_i$ for any $i \in 2 \dots n$ and $\mathfrak{p}_1 = \mathfrak{a} + uR$. In fact $\mathfrak{a} \neq 0$, as R is an integral domain and hence $R/\mathfrak{a}$ is a principal ring by (ii). And as $\mathfrak{p}_1/\mathfrak{a}$ is an ideal of $R/\mathfrak{a}$, there is some $u \in R$ such that

$$\mathfrak{p}_1 \Big/ \mathfrak{a} \;=\; (u+\mathfrak{a})^R \Big/ \mathfrak{a} \;=\; \mathfrak{a} + uR \Big/ \mathfrak{a}$$

By the correspondence theorem we find $\mathfrak{p}_1 = \mathfrak{a} + uR$ as $\mathfrak{a} \subseteq \mathfrak{p}_1$. Thus suppose $u \in \mathfrak{p}_1^2$, then $\mathfrak{p} = \mathfrak{a} + uR \subseteq \mathfrak{p}_1^2 \subseteq \mathfrak{p}_1$ and hence $\mathfrak{p}_1 = \mathfrak{p}_1^2$. Dividing by $\mathfrak{p}_1$ we would find $R = \mathfrak{p}_1$, a contradiction. And if we suppose $u \in \mathfrak{p}_i$ then likewise $\mathfrak{p}_1 = \mathfrak{a} + uR \subseteq \mathfrak{p}_i$. But as $\mathfrak{p}_1$ already is maximal this would imply $\mathfrak{p}_1 = \mathfrak{p}_i$ a contradiction (to $i \neq 1$). (4) now we prove that $uR = \mathfrak{p}_1 \mathfrak{q}_1 \dots \mathfrak{q}_m$ for some prime ideals $\mathfrak{q}_j \notin \mathcal{P}$. First of all uR admits a decomposition $uR = \mathfrak{q}_0 \dots \mathfrak{q}_m$ according to (b). Then $\mathfrak{q}_0 \dots \mathfrak{q}_m = uR \subseteq \mathfrak{p}_1$ and hence $\mathfrak{q}_0 \subseteq \mathfrak{p}_1$ for some $j \in 0 \dots m$, as $\mathfrak{p}_1$ is prime. Without loss of generality we may assume $j = 0$. Then $\mathfrak{q}_0 \subseteq \mathfrak{p}_1$ and this means $\mathfrak{q}_0 = \mathfrak{p}_1$, as $\mathfrak{q}_0$ is maximal (it

is non-zero, prime). Thus we have established the decomposition $uR = \mathfrak{p}_1\mathfrak{q}_1\dots\mathfrak{q}_m$, now assume $\mathfrak{q}_j \in \mathcal{P}$ for some $j \in 1\dots m$. If we had $\mathfrak{q}_j = \mathfrak{p}_i$ for some $i \in 2\dots n$ then $u \in uR \subseteq \mathfrak{p}_1$ in contradiction to (3). And if we had $\mathfrak{q}_j = \mathfrak{p}_1$ then $u \in uR \subseteq \mathfrak{p}_1^2$ in contradiction to (3) again. (5) Thus the $\mathfrak{q}_j \notin \mathcal{P}$ are principal ideals, say $\mathfrak{q}_j = q_jR$. Then we let $q := q_1\dots q_m$ and thereby find $uR = \mathfrak{p}_1\mathfrak{q}_1\dots\mathfrak{q}_m = \mathfrak{p}_1(qR)$. Thus $uR \subseteq qR$, say $u = qv$ for some $v \in R$. Then dividing by qR we find $\mathfrak{p}_1 = (u/q)R = vR$ such that $\mathfrak{p}_1 \in \mathcal{P}$ - a contradiciton at last.

□

Proof of (2.79):
It remains to prove statement (iv) of (2.79), as parts (i), (ii) and (iii) have already been proved on page 1054. So by assumption every prime ideal $\mathfrak{p}$ of R is generated by *one* element $\mathfrak{p} = pR$. In particular any prime ideal $\mathfrak{p}$ is generated by *finitely many* elements. Thus R is notherian by property (d) in (2.34). Further $0 \neq \mathfrak{p} = pR$ implies p to be prime by (2.58.(ii)) (and as R is an integral domain this also means that p is irreducible due to (2.58.(v))). In particular any nonzero prime ideal $0 \neq \mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ contains a prime element $p \in \mathfrak{p}$ (namely p with $\mathfrak{p} = pR$). And thus R is an UFD according to property (e) in (2.60). And by (2.65) this implies that R even is a normal domain. Now regard a non-zero prime ideal $0 \neq \mathfrak{p} = pR \trianglelefteq_{\mathfrak{i}} R$ again and suppose $\mathfrak{p} \subseteq \mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ for some ideal $\mathfrak{a}$ of R. If $\mathfrak{a} \neq R$ then $\mathfrak{a}$ is contained in some maximal ideal $\mathfrak{a} \subseteq \mathfrak{m} \trianglelefteq_{\mathfrak{i}} R$ of R. And as any maximal ideal $\mathfrak{m}$ is prime, by assumption there is some $m \in R$ such that $\mathfrak{m} = mR$. Now $pR = \mathfrak{p} \subseteq \mathfrak{a} \subseteq \mathfrak{m} = mR$ implies $m \mid p$. That is there is some $q \in R$ such that $qm = p$. But as p is irreducible, this implies $q \in R^*$ (as $m \in R^*$ would imply $\mathfrak{m} = R$). That is $p \approx m$ and hence $\mathfrak{p} = \mathfrak{m}$ such that $\mathfrak{p} = \mathfrak{a}$, as well. This mean that $\mathfrak{p}$ already is a maximal ideal of R. Altogether we have proved, that R is a normal, noetherian domain in which any non-zero prime ideal is maximal. But this means that R is a Dedekind domain according to (c) in (2.159). Now consider any ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$. Then due to (b) (2.159) there are prime ideals $\mathfrak{p}_1,\dots,\mathfrak{p}_n \trianglelefteq_{\mathfrak{i}} R$ such that $\mathfrak{a} = \mathfrak{p}_1\dots\mathfrak{p}_n$. By assumption there are $p_i \in R$ such that $\mathfrak{p}_i = p_iR$ and hence $\mathfrak{a} = (p_1R)\dots(p_nR) = (p_1\dots p_n)R$ is a principal ideal, too. As $\mathfrak{a}$ has been arbitrary, this finally means that R is a PID. □

Proof of (3.142):
As in the definition of the tensor product let us denote $X := M_1 \times \dots \times M_n$. Let us first define the map $\widetilde{\varphi}$ from $R^{\oplus X}$ to N, by virtue of

$$\widetilde{\varphi} \;:\; \sum_{x\in X} a_x e_x \mapsto \sum_{x\in X} a_x \varphi(x)$$

From this definition it is clear, that $\widetilde{\varphi}$ is a homomorphism of R-modules (as it has been defined, by linear expansion of $e_x \mapsto \varphi(x)$). Also recall the definition of T to be the sub-module generated by the elements $s(i,x,a)$ and $a(i,x,y_i)$. As φ is R-multilinear we get

$$\begin{aligned}
\widetilde{\varphi}(s(i,x,a)) &= a\varphi(x_1,\dots,x_i,\dots,x_n) - \varphi(x_1,\dots,ax_i,\dots,x_n)\\
&= 0\\
\widetilde{\varphi}(a(i,x,y_i)) &= \varphi(x_1,\dots,y_i,\dots,x_n) + \varphi(x_1,\dots,y_i,\dots,x_n)\\
&\quad -\varphi(x_1,\dots,x_i+y_i,\dots,x_n)\\
&= 0
\end{aligned}$$

where we denoted $x = (x_1,\dots,x_n)$. As T is generated by these elements, we get $\widetilde{\varphi}(t) = 0$ for any $t \in T$

and that is $T \subseteq \mathrm{kn}(\varphi)$. Hence $\widetilde{\varphi}$ induces a map $\overline{\varphi}$ of the form

$$\overline{\varphi} \ : \ {R^{\oplus X}}\Big/{T} \to N \ : \ \sum_{x\in X} a_x e_x + T \mapsto \sum_{x\in X} a_x \varphi(x)$$

As this is the tensor product $M_1 \otimes \ldots \otimes M_n = R^{\oplus X}/T$ (and $x_1 \otimes \ldots \otimes x_n = e_x + T$) this is the *existence* of the homomorphism $\overline{\varphi}$. It remains to prove its *uniqueness*: That is we consider some R-linear map $\psi : M_1 \otimes \ldots \otimes M_n \to N$ such that $\varphi = \psi\tau$. That is for any $x_j \in M_j$ (where $j \in 1 \ldots n$) we get

$$\varphi(x_1, \ldots, x_n) \ = \ \psi(x_1 \otimes \ldots \otimes x_n)$$

but as $M_1 \otimes \ldots \otimes M_n$ is generated by the elements of the form $x_1 \otimes \ldots \otimes x_n$ and ψ and $\overline{\varphi}$ have to coincide on these elements this already implies $\psi = \overline{\varphi}$.
So we have proved the well-definedness of $\varphi \mapsto \overline{\varphi}$. Next we want to prove, that this map truly is a homomorphism of R-modules. That is we consider any two multi-linear maps φ and ψ from $M_1 \times \cdots \times M_n$ to N. If now $a \in R$ is any scalar then from $\overline{a\varphi}\tau = a\varphi$ we get $\overline{a\varphi}(x_1 \otimes \ldots \otimes x_n) = (a\varphi)(x_1, \ldots, x_n) = a\varphi(x_1, \ldots, x_n) = a\overline{\varphi}(x_1 \otimes \ldots \otimes x_n)$ and hence $\overline{a\varphi} = a\overline{\varphi}$ as these elements generate $M_1 \times \cdots \times M_n$. Likewise $\overline{\varphi + \psi} = (\varphi + \psi)\tau$ implies $(\overline{\varphi + \psi})(x_1 \otimes \ldots \otimes x_n) = (\varphi + \psi)(x_1, \ldots, x_n) = \varphi(x_1, \ldots, x_n) + \psi(x_1, \ldots, x_n) = \overline{\varphi}(x_1 \otimes \ldots \otimes x_n) + \overline{\psi}(x_1 \otimes \ldots \otimes x_n)$ such that $\overline{\varphi + \psi} = \overline{\varphi} + \overline{\psi}$ again. So we have also proved the homomorphism property and it only remains to show the bijectivety: The injectivety is clear again, as $\overline{\varphi} = \overline{\psi}$ implies $\varphi = \overline{\varphi}\tau = \overline{\psi}\tau = \psi$. And given any homomorphism $\alpha : M_1 \times \cdots \times M_n \to N$ let us define $\varphi : X \to N$ by $\varphi(x_1, \ldots, x_n) := \alpha(x_1 \otimes \ldots \otimes x_n)$. Then it is clear, that $\varphi = \alpha\tau$ by construction and hence φ is R-multi-linear. But from this we also get $\alpha = \overline{\varphi}$ which in turn is the surjectivety of $\varphi \mapsto \overline{\varphi}$. □

Proof of (3.144):

(i) Let us abbreviate $M := M_1 \otimes \ldots \otimes M_n$ and $M_\sigma := M_{\sigma(1)} \otimes \ldots \otimes M_{\sigma(n)}$. It is clear that for any permutation $\sigma \in S_n$ the following map is (bijective and) R-multilinear

$$\lambda_\sigma \ : \ \bigoplus_{i=1}^{n} M_i \to \bigoplus_{i=1}^{n} M_{\sigma(i)} : (x_1, \ldots, x_n) \mapsto (x_{\sigma(1)}, \ldots, x_{\sigma(n)})$$

Hence the composition $\tau\lambda_\sigma$ (where τ is the standard map, that turns tuples into tensors) which takes $(x_1, \ldots, x_n)$ to $x_{\sigma(1)} \otimes \ldots \otimes x_{\sigma(n)}$ is R-multilinear again. According to the universal property of tensor products (3.142) it therefore induces an R-linear map $\pi_\sigma := \overline{\tau\lambda_\sigma} : M \to M_\sigma$, by linear expansion of $x_1 \otimes \ldots \otimes x_n \mapsto x_{\sigma(1)} \otimes \ldots \otimes x_{\sigma(n)}$. It is clear that π_σ admits an inverse - namely $\pi_{\sigma^{-1}}$ and hence is is the R-module isomorphism that has been claimed

$$\pi_\sigma \ : \ M \ \xrightarrow{\sim} \ M_\sigma$$

(ii) In this prove let us abbreviate $M := M_1 \otimes \ldots \otimes M_n$ and $N(j) := M_{i(j,1)} \otimes \ldots M_{i(j,r(j))}$ for $j \in 1 \ldots s$. Then we need to show the isomorphy of $M \ \cong_{\mathsf{m}} \ N(1) \otimes \ldots \otimes N(s)$. We will prove this statement by induction on s, the case $s = 1$ having been proved in (i). In the case $s = 2$ we are given two sets $I' := I(1)$ and $I'' := I(2)$ such that $I = I' \cup I''$ and $I' \cap I'' = \emptyset$. Likewise let $M' := N(1)$ and $M'' := N(2)$. By renaming let us assume $I' = \{\, 1, \ldots, r-1 \,\}$ and $I'' = \{\, r, \ldots, n \,\}$ (note that the

order of the indexes does not matter, according to (i)). Then we will show the following isomorphy of R-modules

$$M \xrightarrow{\sim} M' \otimes M'' \,:\, x_1 \otimes \ldots \otimes x_n \mapsto (x_1 \otimes \ldots \otimes x_{r-1}) \otimes (x_r \otimes \ldots \otimes x_n)$$

To do this note that the map $\varphi : M_1 \times \cdots \times M_n \to M' \otimes M''$ given, by $\varphi(x_1, \ldots, x_n) := (x_1 \otimes \ldots \otimes x_{r-1}) \otimes (x_r \otimes \ldots \otimes x_n)$ is R-multi-linear. We will prove this for the first argument only, as the other arguments are completely analogous:

$$\begin{aligned}
\varphi(ax_1, x_2, \ldots, x_n) &= (ax_1) \otimes x_2 \otimes \ldots \otimes x_n \\
&= a(x_1 \otimes x_2 \otimes \ldots \otimes x_n) \\
&= a\varphi(x_1, x_2, \ldots, x_n) \\
\varphi(x_1 + x_1', x_2, \ldots, x_n) &= (x_1 + x_1') \otimes x_2 \otimes \ldots \otimes x_n \\
&= x_1 \otimes x_2 \otimes \ldots \otimes x_n + x_1' \otimes x_2 \otimes \ldots \otimes x_n \\
&= \varphi(x_1, x_2, \ldots, x_n) + \varphi(x_1', x_2, \ldots, x_n)
\end{aligned}$$

Therefore the universal property (3.142) yields an R-linear map $\Phi := \overline{\varphi} : M \to M' \otimes M''$ which is defined by linear expansion of $x_1 \otimes \ldots \otimes x_n \mapsto (x_1 \otimes \ldots \otimes x_{r-1}) \otimes (x_r \otimes \ldots \otimes x_n)$ so it only remains to show the bijectivity of this map. In order to do so, let us construct the inverse map, starting with $\psi : M' \times M'' \to M$ defined by linear expansion of

$$\psi \,:\, (x_1 \otimes \ldots \otimes x_{r-1}, x_r \otimes \ldots \otimes x_n) \mapsto x_1 \otimes \ldots \otimes x_n$$

which is clearly well-defined, as the tensor product identifies more elements, than the direct sum does. And it also is R-multi-linear, as it has been defined by linear expansion. Thus we again find an R-linear map $\Psi := \overline{\psi} : M' \otimes M'' \to M$ by linear expansion of $(x_1 \otimes \ldots \otimes x_{r-1}) \otimes (x_r \otimes \ldots \otimes x_n) \mapsto x_1 \otimes \ldots \otimes x_n$. It is obvious that Ψ is the inverse of Φ which makes Φ and isomorphism. For arbitrary $s \geq 2$ let us denote $I' := I(1)$ and $I'' := I(2) \cup \cdots \cup I(s)$. For ease of notation we again assume that $I' = \{1, \ldots, r-1\}$ such that $I'' = \{r, \ldots, n\}$ as well. In the case $s = 2$ we have just shown the isomorphy

$$M \xrightarrow{\sim} M' \otimes M'' \,:\, x_1 \otimes \ldots \otimes x_n \mapsto (x_1 \otimes \ldots \otimes x_{r-1}) \otimes (x_r \otimes \ldots \otimes x_n)$$

(note that this map and all the maps to follow are uniquely determined by their action on the pure tensor products and act by linear expansion on linear combinations of these). And by induction hypothesis we can rely on the isomorphy

$$\begin{aligned}
\bigotimes_{i=r}^{n} M_i &\xrightarrow{\sim} \bigotimes_{j=2}^{s} N(j) \\
x_r \otimes \ldots \otimes x_n &\mapsto \otimes_{j=2}^{s} \big(\otimes_{k=1}^{r(j)} x_{i(j,k)} \big)
\end{aligned}$$

So combining these two we have arrived at the following isomorphy

$$\begin{array}{rcl} M & \xrightarrow{\sim} & N(1) \otimes \left(\bigotimes_{j=2}^{s} N(j) \right) \\ x_1 \otimes \ldots \otimes x_n & \mapsto & (x_1 \otimes \ldots \otimes x_{r-1}) \otimes \left(\otimes_{j=2}^{s} \left(\otimes_{k=1}^{r(j)} x_{i(j,k)} \right) \right) \end{array}$$

But for any R-modules $N(1)$, $N(2)$ to $N(s)$ the case $s = 2$ has also proved the following isomorphy of R-modules

$$\begin{array}{rcl} \bigotimes_{j=1}^{n} N(j) & \xrightarrow{\sim} & N(1) \otimes \left(\bigotimes_{j=2}^{s} N(j) \right) \\ n_1 \otimes \ldots \otimes n_s & \mapsto & n_1 \otimes (n_2 \otimes \ldots \otimes n_s) \end{array}$$

So attaching the inverso of this isomorphism to the isomorphism we have constructed so far, we have finally arrived at the isomorhism, that has been given in the claim

$$\begin{array}{rcl} M & \xrightarrow{\sim} & \bigotimes_{j=1}^{s} N(j) \\ x_1 \otimes \ldots \otimes x_n & \mapsto & \otimes_{j=1}^{s} \left(\otimes_{k=1}^{r(j)} x_{i(j,k)} \right) \end{array}$$

(iii) Let us denote $A := A_1 \times \cdots \times A_n$ and $P := A_1 \otimes \ldots \otimes A_n$ (as an R-module). Let us also abbreviate $x = (x_1, \ldots, x_n)$ and $y = (y_1, \ldots, y_n) \in A$. Then, for a fixed y, we now regard the map

$$\mu_y : A \to P : (x_1, \ldots, x_n) \mapsto (x_1 y_1) \otimes \ldots \otimes (x_n y_n)$$

Note that the multiplication $x_i y_i$ is that of the semi-algebra A_i. It is easy to see that this map is R-multi-linear - we will verify this for the first component A_i only (as the others are completely analogous):

$$\begin{array}{rcl} \mu_y(a x_1, x_2, \ldots, x_n) & = & (a x_1 y_1) \otimes (x_2 y_2) \otimes \ldots \otimes (x_n y_n) \\ & = & a (x_1 y_1) \otimes (x_2 y_2) \otimes \ldots \otimes (x_n y_n) \\ & = & a \mu_y(x_1, x_2, \ldots, x_n) \\ \mu_y(x_1 + x_1', x_2, \ldots, x_n) & = & ((x_1 + x_1') y_1) \otimes (x_2 y_2) \otimes \ldots \otimes (x_n y_n) \\ & = & (x_1 y_1) \otimes (x_2 y_2) \otimes \ldots \otimes (x_n y_n) \\ & & + (x_1' y_1) \otimes (x_2 y_2) \otimes \ldots \otimes (x_n y_n) \\ & = & \mu_y(x_1, x_2, \ldots, x_n) + \mu_y(x_1', x_2, \ldots, x_n) \end{array}$$

Therefore μ_y induces an R-linear map $\lambda_y := \overline{\mu_y} : P \to P$ again, by virtue of the universal property (3.142), by linear expansion of the the operation $x_1 \otimes x_2 \otimes \ldots \otimes x_n \mapsto (x_1 y_1) \otimes (x_2 y_2) \otimes \ldots \otimes (x_n y_n)$. If we are now given some $b_j \in R$ and $y(j) = (y_{j,1}, \ldots, y_{j,n}) \in A$ (where $j \in 1 \ldots \ell$) then

the linear combination of R-linear maps $b_1\lambda_{y(1)} + \ldots b_\ell\lambda_{y(\ell)}$ is given to be the following:

$$\sum_{i=1}^{k} a_i\, x_{i,1} \otimes \ldots \otimes x_{i,n} \;\mapsto\; \sum_{i=1}^{k}\sum_{j=1}^{\ell} a_i\, b_j\, (x_{i,1}y_{j,1}) \otimes \ldots \otimes (x_{i,n}y_{j,n})$$

So this is precisely the expression we have used to define the multiplication on P. And as the b_j and $y(j)$ have been arbitrary this means the expression is truly well-defined. And the properties of an R-algebra (like associativity, distributivity and compatibility with the scalar multiplication) are immediately clear by regarding this explicit definition.

□

Proof of (3.145):
Existence: Clearly the map $\alpha : A_1 \times \cdots \times A_n \to B$ defined by $\alpha(x_1, \ldots, x_n) := \alpha_1(x_1) \cdot \cdots \cdot \alpha_n(x_n)$ is R-multilinear. Hence by the universal property (3.142) of tensor products it gives rise to a well defined, R-module homomorphism $\overline{\alpha}$ which is defined by linear expansion of

$$\overline{\alpha} \;:\; A_1 \otimes \ldots \otimes A_n \to B \;:\; x_1 \otimes \ldots \otimes x_n \mapsto \alpha_1(x_1) \cdot \cdots \cdot \alpha_n(x_n)$$

It remains to prove that $\overline{\alpha}$ truly is multiplicative. But of course it suffices to verify this for pure tensors, as these generate $A_1 \otimes \ldots \otimes A_n$ already. So compute

$$\begin{aligned}
\overline{\alpha}\left(\left(\bigotimes_{i=1}^{n} x_i\right) \cdot \left(\bigotimes_{i=1}^{n} y_i\right)\right) &= \overline{\alpha}\left(\bigotimes_{i=1}^{n}(x_i y_i)\right) \\
&= \prod_{i=1}^{n} \alpha_i(x_i y_i) \;=\; \prod_{i=1}^{n} \alpha_i(x_i)\alpha_i(y_i) \\
&= \left(\prod_{i=1}^{n} \alpha_i(x_i)\right)\left(\prod_{i=1}^{n} \alpha_i(y_i)\right) \\
&= \overline{\alpha}\left(\bigotimes_{i=1}^{n} x_i\right) \cdot \overline{\alpha}\left(\bigotimes_{i=1}^{n} y_i\right)
\end{aligned}$$

Thereby we used the fact that all the $\alpha_i(x_i)$ and $\alpha_j(y_j)$ are mutually commutative, as the images of the α_i is contained in the center of B, by asumption. It remains to verify the *Uniqueness:* by assumption $\overline{\alpha}$ had to satisfy $\overline{\alpha}(\overline{x}_j) = \alpha_j(x_j)$. But it is clear that $\prod_i \overline{x}_i = \otimes_i x_i$ so again we may compute

$$\overline{\alpha}\left(\bigotimes_{i=1}^{n} x_i\right) \;=\; \overline{\alpha}\left(\prod_{i=1}^{n} \overline{x}_i\right) \;=\; \prod_{i=1}^{n} \overline{\alpha}\,(\overline{x}_i) \;=\; \prod_{i=1}^{n} \alpha_i(x_i)$$

That is: the restrictions we imposed on $\overline{\alpha}$ uniquely determine the action of $\overline{\alpha}$ on the pure tensors $x_1 \otimes \ldots \otimes x_n$. But as these generate $A_1 \otimes \ldots \otimes A_n$ and $\overline{\alpha}$ is R-linear, this determines $\overline{\alpha}$ for all tensor elements. □

Proof of (3.146):

(i) Since M is an R-module and R is a *commutative* ring the map $R \times M \to M : (a, x) \mapsto ax$ is bilinear. So by the universal property of tensor products (3.142) we get a well-defined R-linear map $R \otimes M \to M$ by linear expansion of $a \otimes x \mapsto ax$. This clearly is surjective, as $1 \otimes x \mapsto x$ for

any $x \in M$ and if $ax = by$, then $a \otimes x = a(1 \otimes x) = 1 \otimes ax = 1 \otimes by = b(1 \otimes y) = b \otimes y$ which also is the injectivety of this map.

(ii) According to (3.40.(vi)) $M/\mathfrak{a}M$ is an $(R/\mathfrak{a})$-module under the scalar multiplication $(b + \mathfrak{a})(x + \mathfrak{a}M) := bx + \mathfrak{a}M$. Hence the map of the scalar multiplication is well-defined and R-bilinear

$$\varphi \ : \ {}^{R}\Big/_{\mathfrak{a}} \times M \to {}^{M}\Big/_{\mathfrak{a}M} \ : \ (b + \mathfrak{a}, x) \mapsto bx + \mathfrak{a}M$$

Hence (3.142) tells us that there is an R-linear map $\Phi := \overline{\varphi}$ again, which is given by linear expansion of

$$\Phi \ : \ {}^{R}\Big/_{\mathfrak{a}} \otimes M \to {}^{M}\Big/_{\mathfrak{a}M} \ : \ (b + \mathfrak{a}) \otimes x \mapsto bx + \mathfrak{a}M$$

This map clearly is surjective, as for any $x \in M$ we get $(1 + \mathfrak{a}) \otimes x \mapsto x + \mathfrak{a}M$. And to prove the injectivety we will show $\mathrm{kn}(\Phi) = 0$. So consider some element that is mapped to 0 under Φ:

$$\sum_{k=1}^{m} f_k(b_k + \mathfrak{a}) \otimes x_k \ \mapsto \ \sum_{k=1}^{m} f_k b_k x_k + \mathfrak{a}M \ = \ 0 + \mathfrak{a}M$$

which is nothing but $\sum_k f_k b_k x_k \in \mathfrak{a}M$. That is there are some $a_i \in \mathfrak{a}$ and $u_i \in M$ (where $i \in 1 \dots n$) such that $\sum_k f_k b_k x_k = \sum_i a_i u_i$. And using this we can compute

$$\begin{aligned}
\sum_{k=1}^{m} f_k(b_k + \mathfrak{a}) \otimes x_k &= \sum_{k=1}^{m} (1 + \mathfrak{a}) \otimes (f_k b_k x_k) \\
&= (1 + \mathfrak{a}) \otimes \left(\sum_{k=1}^{m} f_k b_k x_k \right) \\
&= (1 + \mathfrak{a}) \otimes \left(\sum_{i=1}^{n} a_i u_i \right) \\
&= \sum_{i=1}^{n} (1 + \mathfrak{a}) \otimes (a_i u_i) \\
&= \sum_{i=1}^{n} (a_i + \mathfrak{a}) \otimes u_i \ = \ 0
\end{aligned}$$

the latter, since $a_i + \mathfrak{a} = 0 + \mathfrak{a}$ annihilating every single summand. Thus we have $\mathrm{kn}(\Phi) = 0$ which is the injectivity of Φ, such that we truly have our isomorphism.

(iii) By construction of the tensor product an element $t \in (R/\mathfrak{a}) \otimes (R/\mathfrak{b})$ is of the form $t = \sum_i a_i(r_i + \mathfrak{a}) \otimes (s_i + \mathfrak{b})$. But it is clear that

$$\sum_{i=1}^{m} a_i(r_i + \mathfrak{a}) \otimes (s_i + \mathfrak{b}) \ = \ (1 + \mathfrak{a}) \otimes \left(\sum_{i=1}^{m} a_i r_i s_i + \mathfrak{b} \right)$$

Hence we have proved, that any element t can be written in the form $(1 + \mathfrak{a}) \otimes (r + \mathfrak{b})$ for some $r \in R$. Now consider the following map

$${}^{R}\Big/_{\mathfrak{a}} \times {}^{R}\Big/_{\mathfrak{b}} \to {}^{R}\Big/_{\mathfrak{a}+\mathfrak{b}} \ : \ (r + \mathfrak{a}, s + \mathfrak{b}) \mapsto rs + (\mathfrak{a} + \mathfrak{b})$$

This is well defined, since $\mathfrak{a}$ and $\mathfrak{b} \subseteq \mathfrak{a} + \mathfrak{b}$ and bilinear, since R is commutative. By the universal

property of the tensor product we find a well-defined, R-linear map by expansion of

$$R\big/_{\mathfrak{a}} \otimes R\big/_{\mathfrak{b}} \to R\big/_{\mathfrak{a}+\mathfrak{b}} \;:\; (r+\mathfrak{a}) \otimes (s+\mathfrak{b}) \mapsto rs + (\mathfrak{a}+\mathfrak{b})$$

Clearly this map is surjective, as for any $s \in R$ we find $(1+\mathfrak{a}) \otimes (s+\mathfrak{b}) \mapsto s + (\mathfrak{a}+\mathfrak{b})$. But it also is injective: To prove this we will show that is has zero-kernel. That is we regard any r, $s \in R$ such that $rs + (\mathfrak{a}+\mathfrak{b}) = 0$. But this means $rs \in \mathfrak{a}+\mathfrak{b}$ or in other words $rs = a+b$ for some $a \in \mathfrak{a}$ and $b \in \mathfrak{b}$. This now enables us compute $(r+\mathfrak{a}) \otimes (s+\mathfrak{b}) = (1+\mathfrak{a}) \otimes (rs+\mathfrak{b}) = (1+\mathfrak{a}) \otimes (a+b+\mathfrak{b}) = (1+\mathfrak{a}) \otimes (a+\mathfrak{b}) = (a+\mathfrak{a}) \otimes (1+\mathfrak{b}) = (0+\mathfrak{a}) \otimes (1+\mathfrak{b}) = 0$.

(iv) The strategy of this proof is very similar to the one in (ii). We take the scalar multiplication of the $U^{-1}R$-module $U^{-1}M$ again

$$\varphi \;:\; U^{-1}R \times M \to U^{-1}M \;:\; \left(\frac{b}{u}, x\right) \mapsto \frac{bx}{u}$$

which is R-bilinear, since it is a scalar multiplication. So this induces an R-linear $\Phi := \overline{\varphi}$ again, which is given by linear expansion of

$$\Phi \;:\; U^{-1}R \otimes M \to U^{-1}M \;:\; \left(\frac{b}{u}\right) \otimes x \mapsto \frac{bx}{u}$$

As before the surjectivity is clear, since $(1/u) \otimes x \mapsto x/u$ for any $x \in M$ and $u \in U$. And to prove the injectivety we will show $\mathrm{kn}(\Phi) = 0$. So consider some element that is mapped to $0 \in U^{-1}M$ under Φ, then all that remains to prove that this element is $0 \in U^{-1}R \otimes M$ already:

$$\sum_{k=1}^{m} a_k \, \frac{b_k}{u_k} \otimes x_k \;\mapsto\; \sum_{k=1}^{m} \frac{a_k b_k x_k}{u_k} \;=\; \frac{0}{1}$$

Let us denote $u := u_1 \cdot \cdots \cdot u_m$ and $\widehat{u}_k := u/u_k \in U$ then the latter means there is some $v \in U$ such that $v \sum_k a_k b_k \widehat{u}_k x_k = 0$. And using this we can compute

$$\begin{aligned}
\sum_{k=1}^{m} a_k \, \frac{b_k}{u_k} \otimes x_k &= \sum_{k=1}^{m} \frac{a_k b_k \widehat{u}_k v}{uv} \otimes x_k \\
&= \frac{1}{uv} \otimes \left(\sum_{k=1}^{m} a_k b_k \widehat{u}_k v x_k \right) \\
&= \frac{1}{uv} \otimes 0 \;=\; 0
\end{aligned}$$

(v) Let us denote the map given in the claim, by $\Phi : (y_i) \mapsto \sum_i m_i \otimes y_i$. This is well-defined, since $y_i = 0$ for all but finitely many $i \in I$ such that in truth the sum is finitely only. Also it is R-linear, which is obvious from the construction. We will now prove its bijectivity by constructing its inverse map $\Lambda = \Phi^{-1}$. To do this let us denote the coordinate function of m_j by $\mu_j : M \to R : \sum_i a_i m_i \mapsto a_j$. This construction is possible, since $\{ m_i \mid i \in I \}$ i a basis and hence the coefficient a_j of $x = \sum_i a_i m_i$ is uniquely determined. Also μ_j is R-linear and we get $\mu_j(m_i) = \delta_{i,j}$ for any i,

$j \in I$ and $x = \sum_i \mu_i(x) m_i$ for any $x \in M$. Therefore the map

$$\lambda \;:\; M \times N \to N^{\oplus I} \;:\; (x,y) \mapsto \big(\mu_i(x)y\big)_{i\in I}$$

is R-bilinear (which is obvious from the construction) and therefore induces an R-linear map $\Lambda := \overline{\lambda}$ by linear expansion of

$$\Lambda \;:\; M \otimes N \to N^{\oplus I} \;:\; x \otimes y \mapsto \big(\mu_i(x)y\big)_{i\in I}$$

Using this map we will now prove that truly $\Lambda = \Phi^{-1}$ is the inverse of Φ, such that Φ truly is an isomorphism. It suffices to check this on the generating set of pure tensors $x \otimes y$, however:

$$\begin{aligned}
\Phi\Lambda(x\otimes y) &= \Phi\big(\mu_i y\big) \\
&= \sum_{i\in I} m_i \otimes (\mu_i(x)y) \\
&= \sum_{i\in I} (\mu_i(x) m_i) \otimes \mu_i(x) y \\
&= \left(\sum_{i\in I} \mu_i(x) m_i\right) \otimes \mu_i(x) y \;=\; x \otimes y \\
\Lambda\Phi(y_i) &= \Lambda\left(\sum_{j\in I} m_j \otimes y_j\right) \\
&= \sum_{j\in I} \Lambda(m_j \otimes y_j) \\
&= \sum_{j\in I} \big(\mu_i(m_j) y_j\big)_{i\in I} \\
&= \sum_{j\in I} \big(\delta_{i,j} y_j\big)_{i\in I} \;=\; (y_i)
\end{aligned}$$

(vi) Since $\big\{\, n_j \mid j \in J \,\big\}$ is an R-basis of N we clearly have the isomorphy $R^{\oplus J} \xrightarrow{\sim} N : (b_j) \mapsto \sum_j b_j n_j$. Also there is a natural isomorphy given by $R^{\oplus(I\times J)} \xrightarrow{\sim} (R^{\oplus I})^{\oplus J} : (a_{i,j}) \mapsto ((a_{i,j})_j)_i$. Inserting the first in the latter we arrive at the following isomorphy of R-modules

$$R^{\oplus(I\times J)} \;\xrightarrow{\sim}\; N^{\oplus I} \;:\; (a_{i,j}) \;\mapsto\; \left(\sum_{j\in J} a_{i,j} n_j\right)_{i\in I}$$

But according to (iv) we also have the isomorphy $N^{\oplus I} \xrightarrow{\sim} M \otimes N$ given by $(y_i) \mapsto \sum_i m_i \otimes y_i$. If we append this isomorphism to the one above we finally arrive at the following isomorphy

$$\Phi \;:\; R^{\oplus(I\times J)} \;\xrightarrow{\sim}\; M \otimes N \;:\; (a_{i,j}) \;\mapsto\; \sum_{i\in I} m_i \otimes \left(\sum_{j\in J} a_{i,j} n_j\right)$$

Using the linearity of the tensor product in the second argument we finally find that this isomorphism truly maps onto an R-linear combination of the $m_i \otimes n_j$

$$\Phi(a_{i,j}) \;=\; \sum_{i\in I}\sum_{j\in J} a_{i,j}\, m_i \otimes n_j \;=\; \sum_{(i,j)\in I\times J} a_{i,j}\, m_i \otimes n_j$$

So this map transfers the standard Euclidean basis $\left\{ e_{(i,j)} \mid i \in I, j \in J \right\}$ of $R^{\oplus(I\times J)}$ onto the pure tensors $\left\{ m_i \otimes y_j \mid i \in I, j \in J \right\}$. And as it is an isomorphism this truly proves, that this set is an R-basis of $M \otimes N$.

(vii) This proof follows the same general ideas as the proof of (iv): Let $M := \oplus_i M_i$ and $N := \oplus_j N_j$ be the direct sums of the R-modules M_i and N_j respectively. We consider the $M_i \subseteq M$ and $N_j \subseteq N$ to be sub-modules of these, canonically. For any fixed $i \in I$ and $j \in J$ we then regard the canonical morphism

$$\iota_{i,j} \ : \ M_i \times N_j \to M \otimes N \ : \ (x_i, y_j) \mapsto x_i \otimes y_j$$

As the tensor product $x_i \otimes y_j$ is bilinear, so is $\iota_{i,j}$ such that it induces an R-linear map $\varphi_{i,j} := \bar{\iota}_{i,j}$, by linear expansion of

$$\varphi_{i,j} \ : \ M_i \otimes N_j \to M \otimes N \ : \ x_i \otimes y_j \mapsto x_i \otimes y_j$$

We now build up the sum of all these R-module homomorphisms, that is we compose $\oplus_{(i,j)}\varphi_{i,j} : \oplus_{i,j}(M_i \otimes N_j) \to (M \otimes N)^{\oplus(I\times J)}$ with the map $\Sigma : (M \otimes N)^{\oplus(I\times J)} \to M \otimes N : (f_{i,j}) \mapsto \sum_i \sum_j f_{i,j}$. Thereby Σ is well-defined as we have $f_{i,j} \neq 0$ for only finitely many $(i,j) \in I \times J$. And it is R-linear by construction. Altogether we obtain an R-linear map $\Phi := \Sigma \oplus_{(i,j)} \varphi_{i,j}$ which is thereby defined by linear expansion of

$$\Phi \ : \ \bigoplus_{(i,j)\in I\times J} (M_i \otimes N_j) \to M \otimes N \ : \ (x_i \otimes y_j) \mapsto \sum_{i\in I}\sum_{j\in J} x_i \otimes y_i$$

We will now prove that Φ is bijective, by constructing its inverse map. To do this note that any $x \in M$ has a unique decomposition into $x = \sum_i x_i$ such that $x_i \in M_i$ for all $i \in I$. Likewise $y \in N$ can be decomposed into $y = \sum_j y_j$ with $y_j \in N_j$.Therefore the following map (the canonocal projection) is well-defined

$$\pi_{i,j} \ : \ M \times N \to M_i \otimes N_j \ : \ (x, y) \mapsto x_i \otimes y_j$$

This map clearly is R-bilinear and hence induces an R-linear map by linear expansion of

$$\psi_{i,j} \ : \ M \otimes N \to M_i \otimes N_j \ : \ x \otimes y \mapsto x_i \otimes y_j$$

Let us join these R-module homomorphisms into the direct sum of the $M_i \otimes N_j$ defining the following R-linear map by linear expansion of

$$\Psi \ : \ M \otimes N \to \bigoplus_{(i,j)\in I\times J} (M_i \otimes N_j) \ : \ x \otimes y \mapsto (x_i \otimes y_i)$$

That is Ψ is precisely the map of which we claim that it is an isomorphism. But we will now prove that Φ already is the inverse of this map $\Psi = \Phi^{-1}$ such that Φ truly is an isomorphism. It suffices to check this on the generating set of pure tensors $x \otimes y$, however:

$$\Phi\Psi(x \otimes y) \quad = \quad \Phi\big(x_i \otimes y_j\big)$$

$$
\begin{aligned}
&= \sum_{i\in I}\sum_{j\in J} x_i \otimes y_j \\
&= \sum_{i\in I} x_i \otimes \left(\sum_{j\in J} y_j\right) \\
&= \sum_{i\in I} x_i \otimes y \\
&= \left(\sum_{i\in I} x_i\right) \otimes y \;=\; x \otimes y \\
\Psi\Phi(x_i \otimes y_j) &= \Psi\left(\sum_{i\in I}\sum_{j\in I} x_i \otimes y_j\right) \\
&= \Psi(\dots \text{see above} \dots) \\
&= \Psi(x \otimes y) \;=\; (x_i \otimes y_j)
\end{aligned}
$$

(viii) For ease of notation let us denote $C := A \times C$ and let us denote the map that is claimed to be an isomorphism by Φ. Note that this is truly well defined, as for all but finitely many $(\alpha, \beta) \in C$ we have $f[\alpha, \beta] = 0$ and hence the sum is finite only, in truth

$$
\begin{aligned}
\Phi \;:\; R\left[x \mid C\right] &\to R\left[s \mid A\right] \otimes R\left[t \mid B\right] \\
\sum_{(\alpha,\beta)\in C} f\left[\alpha,\beta\right]\, x^{(\alpha,\beta)} &\mapsto \sum_{(\alpha,\beta)\in C} f\left[\alpha,\beta\right]\, s^{\alpha} \otimes t^{\beta}
\end{aligned}
$$

It also is clear, that Φ is R-linear, by definition of the addition and scalar multiplication in the polynomial ring $R[x \mid C]$. We will now prove that it even is an R-algebra-homomorphism: it is clear that $\Phi(1) = 1$ and we also get

$$
\begin{aligned}
\Phi\big(x^{(\alpha,\beta)} x^{(\gamma,\delta)}\big) &= \Phi\big(x^{(\alpha+\gamma,\beta+\delta)}\big) \;=\; s^{\alpha+\gamma} t^{\beta+\delta} \\
&= \big(s^{\alpha} t^{\beta}\big)\big(s^{\gamma} t^{\delta}\big) \;=\; \Phi\big(x^{(\alpha,\beta)}\big)\, \Phi\big(x^{(\gamma,\delta)}\big)
\end{aligned}
$$

Due to the R-linearity this expands to $\Phi(fg) = \Phi(f)\Phi(g)$ for any two polynomials $f, g \in R[x \mid C]$. So it only remains to show that Φ truly is an R-alebra isomorphism, so we will prove its bijectivity by constructiong its inverse map Ψ again. Let us start with

$$
\begin{aligned}
R\left[s \mid A\right] \times R\left[t \mid B\right] &\to R\left[x \mid C\right] \\
\left(\sum_{\alpha\in A} f[\alpha]\, s^{\alpha}, \sum_{\beta\in B} g[\alpha]\, t^{\beta}\right) &\mapsto \sum_{(\alpha,\beta)\in C} f[\alpha] g[\beta]\, x^{(\alpha,\beta)}
\end{aligned}
$$

This map clearly is R-bilinear and hence induces an R-linear map by virtue of the universal property (3.142) given by linear expansion of

$$
\begin{aligned}
R\left[s \mid A\right] \otimes R\left[t \mid B\right] &\to R\left[x \mid C\right] \\
\left(\sum_{\alpha\in A} f[\alpha]\, s^{\alpha}\right) \otimes \left(\sum_{\beta\in B} g[\alpha]\, t^{\beta}\right) &\mapsto \sum_{(\alpha,\beta)\in C} f[\alpha] g[\beta]\, x^{(\alpha,\beta)}
\end{aligned}
$$

As always it remains to show $\Phi = \Psi^{-1}$ on the generating sets (even an R-basis) $x^{(\alpha,\beta)}$ and $s^{\alpha} \otimes t^{\beta}$

respectively. So let us compute

$$\Psi\Phi\big(x^{(\alpha,\beta)}\big) \;=\; \Psi\big(s^\alpha \otimes t^\beta\big) \;=\; x^{(\alpha,\beta)}$$

$$\Phi\Psi\big(s^\alpha \otimes t^\beta\big) \;=\; \Phi\big(x^{(\alpha,\beta)}\big) \;=\; s^\alpha \otimes t^\beta$$

□

Proof of (3.149):
The claims (i) and (ii) are obvious from the explicit definiton of the tensor product $\varphi_1 \otimes \ldots \otimes \varphi_n$, as:

$$\begin{aligned}
&\left(\bigotimes_{i=1}^n \psi_i\right)\left(\bigotimes_{i=1}^n \varphi_i\right)\left(\sum_{k=1}^m a_k\, x_{1,k} \otimes \ldots \otimes x_{n,k}\right)\\
=\;&\left(\bigotimes_{i=1}^n \psi_i\right)\left(\sum_{k=1}^m a_k\, \varphi_1(x_{1,k}) \otimes \ldots \varphi_n(\otimes x_{n,k})\right)\\
=\;&\sum_{k=1}^m a_k\, \psi_1\varphi_1(x_{1,k}) \otimes \ldots \psi_n\varphi_n(\otimes x_{n,k})\\
=\;&\bigotimes_{i=1}^n(\psi_i\varphi_i)\left(\sum_{k=1}^m a_k\, x_{1,k} \otimes \ldots \otimes x_{n,k}\right)
\end{aligned}$$

So in case all φ_i are bijective we find inverse maps $\varphi_i^{-1} : M_i \to L_i$ such that $\varphi_i\varphi_i^{-1} = \mathbb{1}_i$ and $\varphi_i^{-1}\varphi_i = \mathbb{1}_i$. And due to (i) and (ii) this readily implies

$$\left(\bigotimes_{i=1}^n \varphi_i^{-1}\right)\left(\bigotimes_{i=1}^n \varphi_i\right) \;=\; \bigotimes_{i=1}^n(\varphi_i^{-1}\varphi_i) \;=\; \bigotimes_{i=1}^n \mathbb{1}_i \;=\; \mathbb{1}_{L_1\otimes\ldots\otimes L_n}$$

$$\left(\bigotimes_{i=1}^n \varphi_i\right)\left(\bigotimes_{i=1}^n \varphi_i^{-1}\right) \;=\; \bigotimes_{i=1}^n(\varphi_i\varphi_i^{-1}) \;=\; \bigotimes_{i=1}^n \mathbb{1}_i \;=\; \mathbb{1}_{M_1\otimes\ldots\otimes M_n}$$

Such that $\varphi_1^{-1} \otimes \ldots \otimes \varphi_n^{-1}$ is the inverse map of $\varphi_1 \otimes \ldots \otimes \varphi_n$ and in particular this is the bijectivity of $\varphi_1 \otimes \ldots \otimes \varphi_n$ again. Also if all the φ_i are surjective then for any $y_i \in M_i$ there is some $x_i \in L_i$ such that $\varphi_i(x_i) = y_i$. That is we find that $x_1 \otimes \ldots \otimes x_n$ is mapped to $y_1 \otimes \ldots \otimes y_n$ under $\varphi_1 \otimes \ldots \otimes \varphi_n$. But as the pure tensors $y_1 \otimes \ldots \otimes y_n$ generate $M_1 \otimes \ldots \otimes M_n$ and the y_i have been arbitrary that already is the surjectivity of $\varphi_1 \otimes \ldots \otimes \varphi_n$ again. That is we have proved the first two statements of (iii) as well. The injectivity part of (iii) (where R is a field) is a direct consequence of (iv) however, as in case of a vectorspace M_i *all* sub-modules are complemented. That is since R is a field property (b) of (iv) is granted automatically, so (a) of (iv) already states the injectivity of $\varphi_1 \otimes \ldots \otimes \varphi_n$. It remains to prove (iv):

Due to assumption (2) we have $M_i = \mathrm{im}(\varphi_i) \oplus P_i$ that is any $z_i \in M_i$ can be written in a unique way as $z_i = y_i + p_i$ with $y_i \in \mathrm{im}(\varphi_i)$ and $p_i \in P_i$. And hence we can define R-module homomorphism $\pi_i : M_i \to \mathrm{im}(\varphi_i)$, by letting $\pi_i(z_i) := y_i$ for this y_i. But as φ_i is injective due to assumption (1) and $y_i \in \mathrm{im}(\varphi_i)$ there is a uniquely determined $x_i \in L_i$ such that $\varphi_i(x) = y_i$. That is may even define $\psi_i : M_i \to L_i$ by letting $\psi_i(z_i) := x_i$ for this x_i. By construction it is clear, that $\psi_i\varphi_i(x_i) = \psi_i(y_i) = x_i$

and therefore we get

$$\left(\bigotimes_{i=1}^{n}\psi_i\right)\left(\bigotimes_{i=1}^{n}\varphi_i\right) \;=\; \bigotimes_{i=1}^{n}(\psi_i\varphi_i) \;=\; \bigotimes_{i=1}^{n}\mathbb{1}_i \;=\; \mathbb{1}_{L_1\otimes\ldots\otimes L_n}$$

again which implies the injectivity of $\varphi_1\otimes\ldots\otimes\varphi_n$. Let us now abbreviate $L := \otimes_i L_i$, $M := \otimes_i M_i$ and $\varphi := \otimes_i\varphi_i : L \hookrightarrow M$, $\psi := \otimes_i\psi_i : M \twoheadrightarrow L$. Then we have seen $\psi\varphi = \mathbb{1}_L$ and we pick up $P := \mathrm{kn}(\psi)$. We will first prove that $M = \mathrm{im}(\varphi) + P$, that is we are given some $z \in M$ and need to find $y \in \mathrm{im}(\varphi)$ and $p \in P$ such that $z = y + p$. This can be done by taking $y := \varphi\psi(z) \in \mathrm{im}(\varphi)$ and $p := z - y$. It only remains to show $p \in P = \mathrm{kn}(\psi)$. But this is easy, since

$$\psi(p) = \psi(z-y) = \psi(z) - \psi(y) = \psi(z) - \psi\varphi\psi(z) = \psi(z) - \mathbb{1}_L\psi(z) = 0$$

And in order to prove $\mathrm{im}(\varphi)\cap P = 0$ we consider some $y \in \mathrm{im}(\varphi)\cap P$ that is $\psi(y) = 0$ and $y = \varphi(x)$ for some $x \in L$. And thereby $0 = \psi(y) = \psi\varphi(x) = x$ such that $y = \varphi(0) = 0$. Altogether we have $M = \mathrm{im}(\varphi)\oplus P$, as claimed. □

Proof of (3.151):

(ii) Let us abbreviate the S-modules $P := U^{-1}M$ and $Q := U^{-1}U$. Recall the construction of the tensor product $P\otimes_S Q$ to be the residue module

$$P\otimes_S Q \;=\; S^{\oplus(P\times Q)}\Big/T_S$$

If we denote the canonical basis of $S^{\oplus(P\times Q)}$ by $\{\,f(p,q) \mid p\in P, q\in Q\,\}$ then the sub-module T_S is the sub-module generated by elements of the form $f(p,q)+f(p',q)-f(p+p',q)$ and $f(p,q)+f(p,q')-f(p',q+q')$ but also by $sf(p,q)-f(sp,q)$ and $sf(p,q)-f(p,sq)$ where p, $p'\in P$, q, $q'\in Q$ and $s\in S$.

If we regard P and Q as R-modules P_R and Q_R respectively, then we have $P_R = P$ and $Q_R = Q$ as sets. Therefore the tensor product $P_R\otimes_R Q_R$ is the residue module

$$P_R\otimes_R Q_R \;=\; R^{\oplus(P\times Q)}\Big/T_R$$

We denote the canonical basis of $R^{\oplus(P\times Q)}$ by $\{\,e(p,q) \mid p\in P, q\in Q\,\}$ an T_R is the sub-module generated by the analogous elements, as above - just replace f by e and s by $a\in R$. Therefore we may define

$$\beta \;:\; R^{\oplus(P\times Q)} \;\to\; S^{\oplus(P\times Q)} \;:\; \sum_{k=1}^{m} a_k\, e(p_k,q_k) \;\mapsto\; \sum_{k=1}^{m} a_k\, f(p_k,q_k)$$

By definition β is injective and κ-linear [that is $\beta(ax) = \kappa(a)\beta(x)$]. However β need not be surjective, but it comes close: If we define $u := u_1\ldots u_m \in U$ and $\widehat{u}_k := u/u_k \in U$ then we find

$$\begin{aligned}\sum_{k=1}^{m}\frac{a_k}{u_k}f(p_k,q_k) \;&=\; \frac{1}{u}\sum_{k=1}^{m}\frac{\widehat{u}_k a_k}{1}f(p_k,q_k)\\ &=\; \frac{1}{u}\beta\left(\sum_{k=1}^{m}\widehat{u}_k a_k\, e(p_k,q_k)\right)\end{aligned}$$

As the scalar multiplication on P_R [that is P regarded as an R-module] is defined by $ap = (a/1)p$ we find the following identity

$$\beta\big(ae(p,q) - e(ap,q)\big) \;=\; \frac{a}{1}f(p,q) - f\left(\frac{a}{1}p,q\right) \;\in\; T_S$$

as we may take $s = a/1 \in S$. Likewise $\beta(ae(p,q) - e(p,aq)) \in T_S$ is plain to see. Altogether we find $\beta(T_R) \subseteq T_S$ from the identities

$$\begin{aligned}
\beta\big(e(p,q) + e(p',q) - e(p+p',q)\big) &= f(p,q) + f(p',q) - f(p+p',q)\\
\beta\big(e(p,q) + e(p,q') - e(p,q+q')\big) &= f(p,q) + f(p,q') - f(p,q+q')\\
\beta\big(ae(p,q) - e(ap,q)\big) &= \frac{a}{1}f(p,q) - f\left(\frac{a}{1}p,q\right)\\
\beta\big(ae(p,q) - e(p,aq)\big) &= \frac{a}{1}f(p,q) - f\left(p,\frac{a}{1}q\right)
\end{aligned}$$

Let us denote $1/U := \{\, 1/u \mid u \in U \,\} \subseteq S$ then conversely we find that $sf(p,q) - f(sp,q)$ is contained in $(1/U)\beta(T_R)$. To do this let $s = a/u \in S$ and $p' := sp \in P$, then $(u/1)p' = (a/1)p$ such that

$$\begin{aligned}
& sf(p,q) - f(sp,q)\\
=\;& \frac{a}{u}f(p,q) - f(p',q)\\
=\;& \frac{1}{u}\left(\frac{a}{1}f(p,q) - \frac{u}{1}f(p',q)\right)\\
=\;& \frac{1}{u}\left(\frac{a}{1}f(p,q) - f\left(\frac{a}{1}p,q\right) + f\left(\frac{u}{1}p',q\right) - \frac{u}{1}f(p',q)\right)\\
=\;& \frac{1}{u}\left(\beta\big(ae(p,q) - e(ap,q)\big) - \beta\big(ue(p',q) - e(up',q)\big)\right)
\end{aligned}$$

Likewise $sf(p,q) - f(p,q) \in (1/U)\beta(T_R)$ and altogether this implies the inclusion $T_S \subseteq (1/U)\beta(T_R)$. But as we also have $\beta(T_R) \subseteq T_S$ and T_S is an S-sub-module we find

$$T_S \;\subseteq\; \frac{1}{U}\beta(T_R) \;\subseteq\; \frac{1}{U}T_S \;\subseteq\; T_S \quad\Longrightarrow\quad T_S \;=\; \frac{1}{U}\beta(T_R)$$

As a final preparation we need the following map Φ_s (for any fixed $s \in S$) that is defined using the basis $e(p,q)$ again

$$\Phi_s \;:\; R^{\oplus(P\times Q)} \;\to\; R^{\oplus(P\times Q)} \;:\; \sum_{k=1}^{m} a_k\, e(p_k,q_k) \;\mapsto\; \sum_{k=1}^{m} a_k\, e(sp_k,q_k)$$

By definition it is clear that Φ_s is R-linear and for any $u \in U$ we have $\Phi_{(1/u)}\Phi_u = \mathbb{1}$ such that Φ_u is an automorphism. But for any $s \in S$ we also have $\Phi_s(T_R) \subseteq T_R$. This is due to $s(p+p') = sp + sp'$ and $sap = asp$ (as S is commutative). Therefore we get

$$\begin{aligned}
& \Phi_s\big(e(p,q) + e(p',q) - e(p+p',q)\big)\\
=\;& e(sp,q) + e(sp',q) - e(sp+sp',q)\\
& \Phi_s\big(e(p,q) + e(p,q') - e(p,q+q')\big)\\
=\;& e(sp,q) + e(sp,q') - e(sp,q+q')
\end{aligned}$$

and

$$\begin{aligned}\Phi_s\big(ae(p,q)-e(ap,q)\big) &= ae(sp,q)-e(asp,q)\\ \Phi_s\big(ae(p,q)-e(p,aq)\big) &= ae(sp,q)-e(sp,aq)\end{aligned}$$

which are all contained in T_R again. As T_R is generated by these elements and Φ_s is R-linear this truly means $\Phi_s(T_R) \subseteq T_R$. Let us now regard $\overline{\beta} := \varrho\beta$, that is $\overline{\beta}$ is the κ-linear map that is defined by $\overline{\beta}(x) = \beta(x) + T_S$ and hence is of the form

$$\overline{\beta} \;:\; R^{\oplus(P\times Q)} \;\to\; S^{\oplus(P\times Q)} \Big/ T_S \;=\; P \otimes_S Q$$

Note that in particular $\overline{\beta}(e(p,q)) = f(p,q) + T_S = p \otimes_S q$. Clearly $\overline{\beta}$ is surjective, as β came close to being surjective, such that

$$\sum_{k=1}^{m} \frac{a_k}{u_k}\, p_k \otimes_s q_k \;=\; \overline{\beta}\left(\sum_{k=1}^{m} \widehat{u}_k a_k e\left(\frac{1}{u}p_k, q_k\right)\right)$$

Also $\overline{\beta}(T_R) = \varrho\beta(T_R) \subseteq \varrho(T_S) = 0$ such that $T_R \subseteq \mathrm{kn}(\overline{\beta})$. Conversely if $x \in \mathrm{kn}(\overline{\beta})$ then $\beta(x) + T_S = \overline{\beta}(x) = 0$ which means $\beta(x) \in T_S = (1/U)\beta(T_R)$. That is $\beta(ux) = u\beta(x) \in \beta(T_R)$ for some $u \in U$. Hence $ux \in \beta^{-1}(\beta(T_R))$ and as β is injective this means $ux \in T_R$. Pick up a basis representation of x, that is $x = \sum_k a_k\, e(p_k, q_k)$, then

$$\begin{aligned}0 + T_R \;&=\; ux + T_R \;=\; \sum_{k=1}^{m} a_k\, ue(p_k,q_k) + T_R\\ &=\; \sum_{k=1}^{m} a_k\, e(up_k,q_k) + T_R \;=\; \Phi_u(x) + T_R\end{aligned}$$

That is $\Phi_u(x) \in T_R$ and hence $x = \Phi_{(1/u)}\Phi_u(x) \in T_R$ as $\Phi_{(1/u)}$ is an automorphism with $\Phi_{(1/u)}(T_R) \subseteq T_R$. That is $x \in T_R$ as well, such that $\mathrm{kn}(\overline{\beta}) \subseteq T_R \subseteq \mathrm{kn}(\overline{\beta})$. Then the first isomorphism theorem finally yields the following isomorphy

$$P_R \otimes_R Q_R \;=\; R^{\oplus(P\times Q)} \Big/ T_R \;\xrightarrow{\;\sim\;}\; S^{\oplus(P\times Q)} \Big/ T_S \;=\; P \otimes_S Q$$

Note that by construction as the isomorphy induced by $\overline{\beta}$ the element $p \otimes_R q = e(p,q) + T_R$ is mapped to $\overline{\beta}(e(p,q)) = f(p,q) + T_S = p \otimes_S q$. And as this map is κ-linear and bijective it truly is an isomorphism onto $P \otimes_S Q$ regared as an R-module.

(ii) **Remark:** If you did not like the lengthy, fundamental proof of (ii) above, note that in case of $M = R$ there is a more structural proof of this isomorphy. We start by $S \otimes_R U^{-1}N \xrightarrow{\;\sim\;} U^{-1}N$ using the R-bilinear map $S \times U^{-1}N \to U^{-1}N$ that maps $(a/u, y/v) \mapsto (ay)/(uv)$. By the universal property of the tensor product this map gives rise to a homomorphism of R-modules induced by

$$S \otimes_R U^{-1}N \;\to\; U^{-1}N \;:\; \frac{a}{u} \otimes_R \frac{y}{v} \;\mapsto\; \frac{ay}{uv}$$

Clearly this homomorphism is surjective and it remains to show its injectivity: For this we use that the general element of $S \otimes_R U^{-1}N$ can be written in the form (where $u := \prod_k u_k$ and $v := \prod_k v_k \in$

U and with $\widehat{u}_k := u/u_k$ and $\widehat{v}_k := v/v_k \in U$ we have $y := \sum_k a_k b_k \widehat{u}_k \widehat{v}_k y_k \in N$)

$$\begin{aligned}\sum_{k=1}^{m} b_k \left(\frac{a_k}{u_k} \otimes_R \frac{y_k}{v_k}\right) &= \sum_{k=1}^{m} b_k \left(\frac{a_k \widehat{u}_k}{u} \otimes_R \frac{\widehat{v}_k y_k}{v}\right) \\ &= \sum_{k=1}^{m} b_k \left(\frac{1}{u} \otimes_R \frac{a_k \widehat{u}_k \widehat{v}_k y_k}{v}\right) = \frac{1}{u} \otimes_R \frac{y}{v}\end{aligned}$$

Thereby $1/u \otimes_R y/v$ is mapped to y/uv and this equals $0/1 \in U^{-1}N$ if and only if $wy = 0$ for some $w \in U$. But from this we get

$$w\left(\frac{1}{u} \otimes_R \frac{y}{v}\right) = \frac{1}{u} \otimes_R \frac{wy}{v} = \frac{1}{u} \otimes_R \frac{0}{v} = 0$$

That is the kernel of this map is 0 and hence it is bijective, as well. The claim of (ii) in the case of $M = R$ now follows from (3.146.(i))

$$S \otimes_R U^{-1}N \xrightarrow{\sim} U^{-1}N \xrightarrow{\sim} S \otimes_S U^{-1}N$$

And thereby both $(a/u) \otimes_R (y/v)$ and $(a/u) \otimes_S (y/v)$ are mapped to the same element $(a/u)(y/v) = (ay)/(uv) \in U^{-1}N$, hence the isomorphism is induced by $(a/u) \otimes_R (b/v) \to (a/u) \otimes_S (y/v)$, as claimed.

(i) By (3.146.(iv)) we have the isomorphism $S \otimes M \xrightarrow{\sim} U^{-1}M$ induced by $(a/u) \otimes x \mapsto ax/u$. That is the preimage of $x/u \in U^{-1}M$ is $(1/u) \otimes x \in S \otimes M$. If we also apply this to $U^{-1}N$, then by (3.149.(iii)) we get the isomorphism

$$\begin{aligned}U^{-1}M \otimes U^{-1}N &\xrightarrow{\sim} (S \otimes M) \otimes (S \otimes N) \\ \frac{x}{u} \otimes \frac{y}{v} &\mapsto \left(\frac{1}{u} \otimes x\right) \otimes \left(\frac{1}{v} \otimes y\right)\end{aligned}$$

Due to the associativity and commutativity of the tensor product (3.144) we may rearrange this into the following form

$$\begin{aligned}U^{-1}M \otimes U^{-1}N &\xrightarrow{\sim} (S \otimes S) \otimes (M \otimes N) \\ \frac{x}{u} \otimes \frac{y}{v} &\mapsto \left(\frac{1}{u} \otimes \frac{1}{v}\right) \otimes (x \otimes y)\end{aligned}$$

Applying (ii) to $M = N = R$ we have the isomorphy $S \otimes_R S \xrightarrow{\sim} S$ under $a/u \otimes b/v \mapsto ab/uv$ such that by (3.150) we can continue with

$$\begin{aligned}U^{-1}M \otimes U^{-1}N &\xrightarrow{\sim} S \otimes (M \otimes N) \\ \frac{x}{u} \otimes \frac{y}{v} &\mapsto \frac{1}{uv} \otimes (x \otimes y)\end{aligned}$$

And by (3.146.(iv)) again we have the isomorpy of $S \otimes (M \otimes N)$ and $U^{-1}(M \otimes N)$ induced by $a/u \otimes (x \otimes y) \mapsto a(x \otimes y)/u$. Thus

$$U^{-1}M \otimes U^{-1}N \xrightarrow{\sim} U^{-1}(M \otimes N)$$

$$\frac{x}{u} \otimes \frac{y}{v} \quad \mapsto \quad \frac{x \otimes y}{uv}$$

□

Proof of (3.152):
The computational rules for the kronecker product of matrices could easily be proved by transferring them from the respective properties of R-module-homomorphisms (3.149). However we prefer to give direct, computational proofs of these equations as to be independent of the general theory of tensor-products. Let us start with $\mathbb{1}_m \in \mathrm{mat}_m(R)$ and $\mathbb{1}_n \in \mathrm{mat}_n(R)$. Then clearly the kronecker product $\mathbb{1}_m \otimes \mathbb{1}_n \in \mathrm{mat}_{mn}(R)$ and we can copute its coefficients by (where $i, j \in 1 \dots m$ and $k,l \in 1 \dots n$)

$$[\mathbb{1}_m \otimes \mathbb{1}_n]_{(i,k),(j,l)} \;=\; [\mathbb{1}_m]_{i,j}\,[\mathbb{1}_n]_{k,l} \;=\; \delta_{i,j}\delta_{k,l} \;=\; \delta_{(i,k),(j,l)} \;=\; [\mathbb{1}_{mn}]_{(i,k),(j,l)}$$

So altogether we have $\mathbb{1}_m \otimes \mathbb{1}_n = \mathbb{1}_{mn}$. Now consider the $(m \times n)$-matrices $A = (a_{i,j})$ and $C = (c_{i,j})$ as well as $(p \times q)$-matrices $B = (b_{k,l})$ and $D = (d_{k,l})$. If now $a, b \in R$ are scalars, then we find (since R is commutative)

$$\begin{aligned}
[A \otimes (bB + D)]_{(i,k),(j,l)} &= [A]_{i,j} \cdot [bB + D]_{k,l} \\
&= a_{i,j}\big(bb_{k,l} + d_{k,l}\big) \;=\; ba_{i,j}b_{k,l} + a_{i,j}d_{k,l} \\
&= b\,[A \otimes B]_{(i,k),(j,l)} + [A \otimes D]_{(i,k),(j,l)}
\end{aligned}$$

$$\begin{aligned}
[(aA + C) \otimes B]_{(i,k),(j,l)} &= [aA + C]_{i,j} \cdot [B]_{k,l} \\
&= \big(aa_{i,j} + c_{i,j}\big)b_{k,l} \;=\; aa_{i,j}b_{k,l} + c_{i,j}b_{k,l} \\
&= a\,[A \otimes B]_{(i,k),(j,l)} + [C \otimes B]_{(i,k),(j,l)}
\end{aligned}$$

Such that we get $A \otimes (bB + D) = b(A \otimes B) + A \otimes D$ and $(aA + C) \otimes B = a(A \otimes B) + C \otimes B$. And for the transpose matrices $A^* \in \mathrm{mat}_{n,m}(R)$ and $B^* \in \mathrm{mat}_{q,p}(R)$ we find that

$$\begin{aligned}
[A^* \otimes B^*]_{(j,l),(i,k)} &= [A^*]_{j,i} \cdot [B^*]_{l,k} \\
&= a_{i,j}b_{k,l} \;=\; [A \otimes B]_{(i,k),(j,l)} \\
&= [(A \otimes B)^*]_{(j,l),(i,k)}
\end{aligned}$$

such that $A^* \otimes B^* = (A \otimes B)^*$. Now consider an $(\ell \times m)$-matrix $A = (a_{i,j})$ and a $(m \times n)$-matrix $C = (c_{j,k})$. Then the product AC is the $(\ell \times n)$-matrix given by $[AC]_{i,k} = \sum_j a_{i,j}c_{j,k}$. Likewise for a $(p \times q)$-matrix $B = (b_{f,g})$ and an $(q \times r)$-matrix $D = (d_{g,h})$ the product BD is the $(p \times r)$-matrix with the coefficients $[BD]_{f,h} = \sum_g b_{f,g}d_{g,h}$. Now compute

$$\begin{aligned}
[(A \otimes B)(C \otimes D)]_{(i,f),(k,h)} &= \sum_{(j,g)=1}^{mq} [A \otimes B]_{(i,f),(j,g)}\,[C \otimes D]_{(j,g),(k,h)} \\
&= \sum_{(j,g)=1}^{mq} a_{i,j}b_{f,g}c_{j,k}d_{g,h}
\end{aligned}$$

$$
\begin{aligned}
&= \sum_{j=1}^{m}\sum_{g=1}^{q} a_{i,j}c_{j,k}b_{f,g}d_{g,h} \\
&= \left(\sum_{j=1}^{m} a_{i,j}c_{j,k}\right)\left(\sum_{g=1}^{q} b_{f,g}d_{g,h}\right) \\
&= [AC]_{i,k}\cdot[BD]_{f,h} \\
&= [(AC)\otimes(BD)]_{(i,f),(k,h)}
\end{aligned}
$$

That is we have shown $(A\otimes B)(C\otimes D) = (AC)\otimes(BD)$. In particular we get $(A\otimes \mathbb{1}_p)(\mathbb{1}_n\otimes B) = (A\mathbb{1}_n)\otimes(\mathbb{1}_p B) = A\otimes B$. And if we return to the standard sizes $A = (a_{i,j}) \in \mathrm{mat}_{m,n}(R)$ and $B = (b_{k,l}) \in \mathrm{mat}_{p,q}(R)$ again, then a likewise computetion yields the equality $\mathrm{tr}(A\otimes B) = \mathrm{tr}(A)\cdot\mathrm{tr}(B)$

$$
\begin{aligned}
\mathrm{tr}(A\otimes B) &= \sum_{(i,k)=1}^{mp} [A\otimes B]_{(i,k),(i,k)} \\
&= \sum_{i=1}^{m}\sum_{k=1}^{q} a_{i,i}b_{k,k} \\
&= \left(\sum_{i=1}^{m} a_{i,i}\right)\left(\sum_{k=1}^{q} b_{k,k}\right) \\
&= \mathrm{tr}(A)\cdot\mathrm{tr}(B)
\end{aligned}
$$

□

Proof of (3.154):

(i) Let us first prove the case $n = 2$, that is we are given two E-modules M and N and some elements $x \in M$ and $y \in N$. If $x = 0$, then it is clear that

$$
\begin{aligned}
x\otimes y &= 0_M\otimes y = (0\cdot 0_M)\otimes y \\
&= 0\cdot(0_M\otimes y) = 0_M\otimes(0\cdot y) = 0_M\otimes 0_N = 0
\end{aligned}
$$

and likewise $y = 0$ implies $x\otimes y = 0$. If remains to prove the inverse implication, that is we have $x\otimes y = 0$ and need to show $x = 0$ or $y = 0$. To do this pick up bases $\{ m_i \mid i\in I\}$ of M and $\{ n_j \mid j\in J\}$ of N. Then we find a basis representation $x = \sum_i a_i m_i$ and $y = \sum_j b_j n_j$ where the sums are finite only. Then we see that

$$
0 = x\otimes y = \left(\sum_{i\in I} a_i m_i\right)\otimes\left(\sum_{j\in J} b_j n_j\right) = \sum_{i\in I}\sum_{j\in J} a_i b_j\, m_i\otimes n_j
$$

But in (3.146.(v)) we have seen, that the $m_i\otimes n_j$ form a basis of $M\otimes N$. Therefore for any $i\in I$ and any $j\in J$ the coefficient $a_i b_j = 0$ has to vanish. If $x\neq 0$ then there is some $r\in I$ such that $a_r = 0$ and therefore $a_r b_j = 0$ implies $b_j = 0$ for all $j\in J$. That is we have $y = 0$ (or $x = 0$) as claimed. In case of general $n\geq 3$ we use induction, taking to $M := M_1$, $x := x_1$ and $N := M_2\otimes\ldots\otimes M_n$ resp. to $y := x_2\otimes\ldots\otimes x_n$. Then the tensor product's associativity (3.144.(ii)) $M_1\otimes\ldots\otimes M_n \xrightarrow{\sim} M\otimes N : x_1\otimes\ldots\otimes x_n \mapsto x\otimes y$ turns the assumption $x_1\otimes\ldots\otimes x_n = 0$ into $x\otimes y = 0$ which is equivalent to $x_1 = x = 0$ or $y = 0$. And by induction hypothesis $y = 0$ is

equivalent to one of the x_2 to x_n being zero, as well.

(ii) As in (i) above, let us first prove the case $n = 2$, that is we are given two E-modules M and N and some elements u, $v \in M$ and x, $y \in N$ such that $u \otimes x = v \otimes y \neq 0$. We now pick up bases $\{ m_i \mid i \in I \}$ of M and $\{ n_j \mid j \in J \}$ of N again denote the basis representation of these elements, by $u = \sum_i u_i m_i$, $v = \sum_i v_i m_i$ and $x = \sum_j x_j n_j$, $y = \sum_j y_j n_j$ respectively. Then (as before) $u \otimes x = v \otimes y$ is nothing but $\sum_{i,j} u_i x_j \, m_i \otimes n_j = \sum_{i,j} v_i y_j \, m_i \otimes n_j$ which in turn is $u_i x_j = v_i y_j$ for all $i \in I$ and $j \in J$. We can even multiply this equation with some $\omega_i \in E$ to find $\omega_i u_i x_j = \omega_i v_i y_j$. Summing up all these equations over i yields $\langle (\omega_i) \mid (u_i) \rangle x_j = \langle (\omega_i) \mid (v_i) \rangle y_j$ and as this is true for all $j \in J$ we get $\langle (\omega_i) \mid (u_i) \rangle x = \langle (\omega_i) \mid (v_i) \rangle y$. By assumption we also have $v \otimes y \neq 0$ which by (i) implies $v \neq 0$ (and $y \neq 0$). Therefore we have $(v_i) \neq 0$ such that there is some $(\omega_i) \in E^I$ such that $\langle (\omega_i) \mid (v_i) \rangle \neq 0$. Letting $b := \langle (\omega_i) \mid (u_i) \rangle / \langle (\omega_i) \mid (v_i) \rangle$ for this (ω_i) we hence get $y = bx$. In complete analogy we can find some $a \in E$ such that $v = au$. Now compute

$$u \otimes v \;=\; v \otimes y \;=\; (au) \otimes (bx) \;=\; ab\,(u \otimes x)$$

which is $(ab - 1)(u \otimes v) = 0$. Using (i) and the assumption $u \otimes x \neq 0$ this also implies $ab = 1$. As in (i) we use induction for the general case $n \geq 3$ using the same notation as above $u := x_1$, $x := x_2 \otimes \ldots \otimes x_n$, $v := y_1$ and $y := y_2 \otimes y_n$. Then the assumption $x_1 \otimes \ldots \otimes x_n = y_1 \otimes \ldots \otimes y_n$ turns into $u \otimes x = v \otimes y$ from which we get $v = a_1 u$ and $y = a_2 x$ for some a_1 and $a_2 \in R$ with $a_1 a_2 = 1$. Letting $z := a_2 x = (a_2 x_2) \otimes x_3 \otimes \ldots x_n$ we get $y = z$ which by induction hypothesis yields some $b_i \in R$ such that $y_2 = b_2 z_2 = b_2 a_2 x_2$ and $y_i = b_i z_i = b_i x_i$ for $i \in 3 \ldots n$ with $b_2 \ldots b_n = 1$. Multiplying all the coefficients we find $a_1 (b_2 a_2) b_3 \ldots b_n = (a_1 a_2)(b_2 \ldots b_n) = 1$, as claimed.

(iii) Let $X_i = \{ x_{i,k} \mid k \in K(i) \}$ for some index set $K(i) \neq \emptyset$. And for any $i \in 1 \ldots n$ let us regard the canonical homomorphism

$$\varrho_i : R^{\oplus K(i)} \to M_i \;:\; (a_k) \mapsto \sum_{k \in K(i)} a_k x_{i,k}$$

Let us also abbreviate $X := X_1 \otimes \ldots \otimes X_n$ and the tensor products of $M := M_1 \otimes \ldots \otimes M_n$ and of these homomorphisms by $\varrho := \otimes_1 \otimes \ldots \otimes \varrho_n$. Then X_i generates M_i iff ϱ_i is surjective. But in this case we see that ϱ is surjective again, due to (3.149.(iv)) which means that X generates M. Likewise X_i is linear independent iff ϱ_i is injective. And in this case ι is injective again, since E is a field and we have (3.149.(iv)) again. But this is nothing but the linear independence of X. Finally X_i is a basis of M_i iff ϱ_i is bijective. And in this case (3.149.(iv)) again implies, that ϱ is bijective, such that X is a basis of M.

(vi) Pick up a basis $\{ n_j \mid j \in J \}$ of N and for each y_k and $y'_k \in N$ pick up basis representations $y_k = \sum_j a_{j,k} n_j$ and $y'_k = \sum_j a'_{j,k} n_j$ respectively. Then we compute

$$\sum_{j \in J} \sum_{k=1}^{m} a_{j,k} \, x_k \otimes n_j \;=\; \sum_{k=1}^{m} x_k \otimes y_k \;=\; \sum_{k=1}^{m} x_k \otimes y'_k \;=\; \sum_{j \in J} \sum_{k=1}^{m} a'_{j,k} \, x_k \otimes n_j$$

But as the x_k and n_j are lineary independent we know by (iii) that the tensors $x_k \otimes n_j$ are linear

independent in $M \otimes N$. And hence we get $a_{j,k} = a'_{j,k}$ for any $j \in J$ and $k \in 1 \dots m$. But that is $y_k = y'_{j,k}$ for any $k \in 1 \dots m$ again, as had been claimed.

(iv) Take a look at the embeddings $\iota_i : U_i \hookrightarrow M_i : x_i \mapsto x_i$, as these are injective and E is a field we find that $\iota_1 \otimes \dots \otimes \iota_n$ is injective again, according to (3.149.(iii)). In particular we get the explicit representation of $U_1 \otimes \dots \otimes U_n$ as a subset of $M_1 \otimes \dots \otimes M_n$

$$\bigotimes_{i=1}^{n} U_i = \left\{ \sum_{k=1}^{m} a_k \, u_{1,k} \otimes \dots \otimes u_{n,k} \;\middle|\; a_k \in E, u_{i,k} \in M_i \right\} \subseteq \bigotimes_{i=1}^{n} M_i$$

The equality for the intersection of subspaces will use inducion on n and will be require the use of (vii). Hence it is proved after that.

(v) The implication " $\Longleftarrow$ " is clear by the explicit representation of the product $U_1 \otimes \dots \otimes U_n$ as a subset of $M_1 \otimes \dots \otimes M_n$ that has been given in (iv). And in the direction " $\Longrightarrow$ " we will only prove $x_{1,k} \in M_1$ for ease of notation. The other cases ($i \in 2 \dots n$) can be shown in complete analogy. So let us denote $M := M_1$ and $N := M_2 \otimes \dots \otimes M_n$ as well as $x_k := x_{1,k} \in M$ and $y_k := x_{2,k} \otimes \dots \otimes x_{n,k} \in N$. Note that according to (iii) $\{ y_1, \dots, y_m \}$ is linear independent again. And we also have the natural isomorphy $M_1 \otimes \dots \otimes M_n \xrightarrow{\sim} M \otimes N : x_{1,k} \otimes \dots \otimes x_{n,k} \mapsto x_k \otimes y_k$. Let us finally abbreviate $U := U_1 \leq_{\mathrm{v}} M$ and $V := U_2 \otimes \dots \otimes U_n \leq_{\mathrm{v}} V$ and regard the canonical homomorphism

$$\varrho \;:\; M \twoheadrightarrow {}^{M}\!/_{U} \;:\; x \mapsto x + U$$

Then $\varrho \otimes N : M \otimes N$ is defined by $x \otimes y \mapsto (x + U) \otimes y$. Using this homomorphism on $t = \sum_k a_k x_k \otimes y_k$ we get

$$\begin{aligned} (\varrho \otimes N)(t) &= (\varrho \otimes N) \left(\sum_{k=1}^{m} a_k \, x_k \otimes y_k \right) \\ &= \sum_{k=1}^{m} a_k (x_k + U) \otimes y_k \;=\; \sum_{k=1}^{m} (a_k x_k + U) \otimes y_k \end{aligned}$$

But by assumption we also have $t \in U_1 \otimes \dots \otimes U_n = U \otimes V$ such that there are some $b_r \in E$ $u_r \in U$ and $v_r \in V$ (where $r \in 1 \dots s$) such that $t = \sum_r b_r u_r \otimes v_r$. Using $\varrho \otimes N$ on t again, this time we find

$$\begin{aligned} (\varrho \otimes N)(t) &= (\varrho \otimes N) \left(\sum_{r=1}^{s} b_r \, u_r \otimes v_r \right) \\ &= \sum_{r=1}^{s} b_r (u_r + U) \otimes v_r \;=\; \sum_{r=1}^{s} b_r (u_r + U) \otimes v_r \\ &= \sum_{r=1}^{s} b_r (0 + U) \otimes v_r \;=\; 0 \;=\; \sum_{k=1}^{m} (0 + U) \otimes y_k \end{aligned}$$

As the y_k are linear independent (vi) now tells us, that for any index $k \in 1 \dots m$ we get $a_k x_k + U = 0 + U$ which is $a_k x_k \in U$. But as $a_k \neq 0$ and E is a field this yields $x_{1,k} = x_k \in U = U_1$ as claimed.

(vii) For the implication " $\Longrightarrow$ " let us suppose $\{ x_1, \dots, x_m \}$ was *not* linear independent, then we have

to prove that m is *not* minimal Without loss of generality (and for ease of notation) let us assume that

$$x_1 \;=\; \sum_{k=2}^{m} b_k x_k$$

for some $b_k \in E$. Then we could rearrange t is such a way as to reduce the number of pure tensors required to build up t

$$\begin{aligned} t \;&=\; \sum_{k=1}^{m} a_k\, x_k \otimes y_k \;=\; a_1\, x_1 \otimes y_1 + \sum_{k=2}^{m} a_k\, x_k \otimes y_k \\ &=\; a_1 \left(\sum_{k=2}^{m} b_k x_k \right) \otimes y_1 + \sum_{k=2}^{m} a_k\, x_k \otimes y_k \\ &=\; \sum_{k=2}^{m} x_k \otimes (a_1 b_k y_1) + \sum_{k=2}^{m} x_k \otimes (a_k y_k) \\ &=\; \sum_{k=2}^{m} x_k \otimes (a_1 b_k y_1 + a_k y_k) \end{aligned}$$

Thus we have discounted the minimality of m by showing $\mu(t) \leq m-1 < m$. Hence the assumption of the linear independance of $\{\, x_1, \ldots, x_m \,\}$ must be false. The case that $\{\, y_1, \ldots, y_m \,\}$ is not linearly independent can be shown in complete analogy. And if $a_k = 0$ then $x_k \otimes y_k$ can be omitted for trivial reasons. For the converse implication " $\Longleftarrow$ " we are given a representation of t with $b_r \neq 0$ and linearly independent $\{\, u_1, \ldots, u_s \,\} \subseteq M$ and $\{\, v_1, \ldots, v_s \,\} \subseteq N$

$$t \;=\; \sum_{r=1}^{s} b_r\, u_r \otimes v_r$$

Let us denote $U := \mathrm{Lh}\{\, u_1, \ldots, u_s \,\} \;\leq_{\mathrm{v}}\; M$ and $V := \mathrm{Lh}\{\, v_1, \ldots, v_s \,\} \;\leq_{\mathrm{v}}\; N$ and consider an arbitrary representation of t in terms of

$$t \;=\; \sum_{k=1}^{m} a_k\, x_k \otimes y_k$$

Then we have to show that $s \leq m$ such that $\mu(t) = s$. Without loss of generality we can also assume $a_k \neq 0$, as this would only increase the number m of pure tensors used. Then the u_r are linearly independent we may append them to a basis $\{\, u_1, \ldots, u_s \,\} \subseteq \{\, u_i \mid i \in I \,\}$ of M. And likewise let $\{\, v_1, \ldots, v_s \,\} \subseteq \{\, v_j \mid j \in J \,\}$ be a basis of N. Then we express the x_k as linear combinations of this basis likewise

$$x_k \;=\; \sum_{i \in I} x_{i,k} u_i \quad \text{and} \quad y_k \;=\; \sum_{j \in J} y_{i,k} v_i$$

Inserting these representations we obtain the following expression of t

$$t \;=\; \sum_{k=1}^{m} a_k\, x_k \otimes y_k \;=\; \sum_{i \in I} \sum_{j \in J} \left(\sum_{k=1}^{m} a_k x_{i,k} y_{j,k} \right) u_i \otimes v_j$$

Note that according to (iii) $\{\, u_i \otimes y_j \mid i \in I, j \in J \,\}$ is a basis of $M \otimes N$. So comparing this representation of t with the one we started with $t = \sum_r b_r u_r \otimes v_r$ we see that for $1 = j = r \in 1 \ldots s$ we

get

$$\sum_{k=1}^{m} a_k x_{r,k} y_{r,k} \;=\; b_r$$

And in case $i \neq j$ (or $i = j \notin 1 \ldots s$ which is of no interest to us however) we likewise see, that

$$\sum_{k=1}^{m} a_k x_{i,k} y_{j,k} \;=\; 0$$

Recall that $b_r \neq 0$ so we may divide the above equation by b_r (also note that thereby $j = r$). So if we denote $p_{k,j} := a_k b_j^{-1} y_{j,k}$ then for any $i, j \in 1 \ldots s$ we altogether find the equality

$$\sum_{k=1}^{m} x_{i,k} p_{k,j} \;=\; \sum_{k=1}^{m} x_{i,k} a_k b_j^{-1} y_{j,k} \;=\; b_j^{-1} \sum_{k=1}^{m} a_k x_{i,k} y_{j,k} \;=\; \delta_{i,j}$$

Thus if we take to the $(m \times s)$-matrix $P := (p_{k,i})$ and to the $(s \times m)$-matrix $X := (x_{i,k})$ over E the above equations turn into nothing but the matrix equation $XP = \mathbb{1}_s$. In particular if we regard P as a linear map $P : R^s \hookrightarrow R^m$ it is injective. And due to dimension reasons this implies $s \leq m$, so s is minimal indeed.

(v) (continued) We will now prove the equality for the intersection of subspaces, that has been postponed so far. The containment "$\subseteq$" is easy to see, just let us abbreviate $U_i := \bigcap_j U_{i,j}$ and consider some $t \in U_1 \otimes \ldots \otimes U_n$. That is $t = \sum_k a_k u_{1,k} \otimes \ldots \otimes u_{n,k}$ for some $u_{i,k} \in U_i$. But as $U_i \subseteq U_{i,j}$ for all $j \in J(i)$ this is $u_{i,k} \in U_{i,j}$ for any $i \in 1 \ldots n$, $j \in J(i)$ and $k \in 1 \ldots m$ such that $t \in U_{1,j(1)} \otimes \ldots \otimes U_{n,j(n)}$ for any $j \in J(1) \times \cdots \times J(n)$ again. Hence t is contained in the intersection of these spaces, as claimed. For the converse inclusion "$\supseteq$" we will use induction on n. First consider the case $n = 2$, that is we are given two E-vectorspaces M and N and families of subspaces $U_i \leq_{\mathrm{v}} M$ and $V_j \leq_{\mathrm{v}} N$ where $i \in I$ and $j \in J$ respectively. Then we have to prove

$$\bigcap_{(i,j) \in I \times J} U_i \otimes V_j \;\subseteq\; \left(\bigcap_{i \in I} U_i \right) \otimes \left(\bigcap_{j \in J} V_j \right)$$

Thus consider some $t \in \bigcap_{(i,j)} U_i \otimes V_j$ that is for any $i \in I$ and any $j \in J$ there are some $a_r(i,j) \in E$, $u_r(i,j) \in U_i$ and $v_r \in V_j$ (where $r \in 1 \ldots s(i,j)$ such that

$$t \;=\; \sum_{k=1}^{s(i,j)} a_r(i,j)\, u_r(i,j) \otimes v_r(i,j)$$

According to (vii) we may take the $a_r(i,j) \neq 0$ and the $u_r(i,j) \in M$ respectively the $v_r(i,j) \in N$ to be E-linearly independent. Now fix any $p \in I$ and $q \in J$ and recall that we still have $t \in U_i \otimes V_j$ then

$$t \;=\; \sum_{k=1}^{s(p,q)} a_r(p,q)\, u_r(p,q) \otimes v_r(p,q) \;\in\; U_i \otimes V_j$$

Then (v) implies that $u_r(p,q) \in U_i$ and $v_r(p,q) \in V_j$ for any $i \in I$ and any $j \in J$ respectively. That is they are contained in the intersection $u_r(p,q) \in U := \bigcap_i U_i$ and $v_r(p,q) \in V := \bigcap_j V_j$ respectively. But this again implies $t \in U \otimes V$ as claimed. For the induction step $n \geq 3$ let us

denote $M := M_1$ and $N := M_2 \otimes \ldots \otimes M_n$ again. Likewise $I := J(1)$ and $J := J(2) \times \cdots \times J(n)$ and $U_i := U_{1,i}$ for $i \in I$ and finally $V_j := U_{2,j(2)} \otimes \ldots \otimes U_{n,j(n)}$ for $j = (j(2), \ldots, j(n)) \in J$ respectively. Then by induction hypothesis we have

$$\bigcap_{j\in J} V_j \;=\; \bigcap_{j\in J(2)\times\cdots\times J(n)} \bigotimes_{i=2}^{n} U_{i,j(i)} \;\subseteq\; \bigotimes_{i=2}^{n} \left(\bigcap_{j\in J(i)} U_{i,j} \right)$$

But in the case $n = 2$ we have just shown that also $\bigcap_{i,j} U_i \otimes V_j \subseteq (\bigcap_i U_i) \otimes (\bigcap_j V_j)$. Thus we may compute

$$\begin{aligned} \bigcap_{i,j} U_i \otimes V_j &\subseteq \left(\bigcap_{i\in I} U_i \right) \otimes \left(\bigcap_{j\in J} V_j \right) \\ &\subseteq \left(\bigcap_{i\in I} U_i \right) \otimes \left(\bigotimes_{i=2}^{n} \left(\bigcap_{j\in J(i)} U_{i,j} \right) \right) \\ &= \bigotimes_{i=1}^{n} \left(\bigcap_{j\in J(i)} U_{i,j} \right) \end{aligned}$$

□

Proof of (3.160):

(i) If M is free with basis $\{ m_i \mid i \in I \}$ then according to (3.146.(iv)) we obtain the following isomorphy of R-modules

$$\Phi \;:\; S^{\oplus I} \;\xrightarrow{\sim}\; M_S \;:\; (s_i) \mapsto \sum_{i\in I} s_i \otimes m_i$$

But Φ clearly not only is R-linear, but even S-linear, as $\Phi(a(s_i)) = \Phi(as_i) = \sum_i (as_i) \otimes m_i = \sum_i a(s_i \otimes m_i) = a \sum_i s_i \otimes m_i = a\Phi(s_i)$. Also $\Phi(s_i)$ is nothing but an S-linear combination of the $1_S \otimes m_i$

$$\Phi\big((s_i)\big) \;=\; \sum_{i\in I} s_i \, (1_S \otimes m_i)$$

That is Φ is precisely the canonical homomorphism $S^{\oplus I}$ onto the linear combinations of the $\{ 1_S \otimes m_i \mid i \in I \} \subseteq M$. And its bijectivity proves that this set truly is an S-basis of M_S.

(ii) We have just seen in (i) that $\{ 1_S \otimes m_i \mid i \in 1 \ldots m \}$ truly is an R-basis of M_S and likewise for N_S. The identity of the matrix representation of φ boils down to a vey short, straightforward computation:

$$\begin{aligned} \varphi_S(1_S \otimes m_j) &= 1_S \otimes \varphi(m_j) \;=\; 1_S \otimes \left(\sum_{i=1}^{m} a_{i,j} n_i \right) \\ &= \sum_{i=1}^{m} a_{i,j} \, 1_S \otimes n_i \;=\; \sum_{i=1}^{m} (a_{i,j} 1_S) \, (1_S \otimes n_i) \end{aligned}$$

(iii) As S is a free R-algebra with $S \neq 0$ we have seen in (3.52.(ii)) that the canonical map $\iota : R \hookrightarrow S : a \mapsto a1_S$ is injective and that there is some sub-module $S' \leq_{\mathsf{m}} S$ such that $S = (S1_S) \oplus S'$.

That is $\mathrm{im}(I) \oplus S' = S$ such that by (3.149.(iv)) we find that $\iota_S := \iota \oplus M : R \otimes M \hookrightarrow S \otimes M$ is injective again. Thereby ι_S is defined by linear expansion of $\iota_S(a \otimes x) = (a1_S) \otimes x$. But due to the isomorphy $\Lambda : R \otimes M \xrightarrow{\sim} M : a \otimes x \mapsto ax$ we can shift ι_S to M, where we get

$$\iota_S \Lambda^{-1} \ : \ M \hookrightarrow M_S \ : \ x \mapsto 1_S \otimes x$$

If the reader is not entirely convinced by this just fix some $x, y \in M$ and compute: $1_S \otimes x = 1_S \otimes y$ is nothing but $\iota_S(1 \otimes x) = \iota_S(1 \otimes y)$. But as ι_S is injective, this means $1 \otimes x = 1 \otimes y$. Now the isomorphy Λ yields $x = \Lambda(1 \otimes x) = \Lambda(1 \otimes y) = y$ which had to be shown.

(iv) Clearly $B \times M_A \to M_B : (b, t) \mapsto bt$ is a bilinear map, such that by the universal property of the tensor-product we find a well-defined homomorphism of A modules, by

$$\Phi \ : \ \left(M_A\right)_B = B \otimes M_A \to M_B \ : \ b \otimes t \mapsto bt$$

On the other hand we clearly get another bilinear map by taking to $B \times M \to (M_A)_B : (b, x) \mapsto b \otimes (1_A \otimes x)$. And by the universal property of the tensor-product again, this yields another well-defined homomorphism of A modules, by

$$\Psi \ : \ M_B = B \otimes M \to \left(M_A\right)_B \ : \ b \otimes x \mapsto b \otimes (1_A \otimes x)$$

And it is easy to see that these maps are mutual inverse of on and another. It suffices to check this on the generating set of pure tensors: $\Phi\Psi(b \otimes x) = \Phi(b \otimes (1_A \otimes x)) = (1_A b) \otimes x = b \otimes x$ and conversely $\Psi\Phi(b \otimes (a \otimes x)) = \Psi(b(a \otimes x)) = \Psi(ab \otimes x) = ab \otimes (1_A \otimes x) = b \otimes (a \otimes x)$. Note that we thereby used the definition of the scalar multiplication in $(M_A)_B$ which is $b(a \otimes x) = ab \otimes x$. Hence Φ is an isomorphism of A-modules, but as it is B-linear as well, we even have an isomorphy of B-modules.

(vi) Let us first prove the well-definedness of $\varphi(S)$. To do this regard the map $S \times M \to s\varphi(x)$. The R-linearity in the first argument is obvious: $(r + s, x) \mapsto (r + s)\varphi(x) = r\varphi(x) + s\varphi(x)$ and $(as, x) \mapsto (as)\varphi(x) = (a1_S s)\varphi(x) = (a1_S)(s\varphi(x)) = a(s\varphi(x))$. Before we proceed with the R-linearity in the second argument recall, that for any $a \in R$ and $s \in S$ we get $(a1_S)s = a(1_S s) = a(s1_S) = s(a1_S)$ since S is an R-algebra. That is $a1_S$ commutes with any $s \in S$. Using this we can compute $(s, x + y) \mapsto s\varphi(x + y) = s(\varphi(x) + \varphi(y)) = s\varphi(x) + s\varphi(y)$ and $(s, ax) \mapsto s\varphi(ax) = s(a1_S)\varphi(x) = (a1_S)s\varphi(x) = a(s\varphi(x))$. Hence by the universal property of tensor products (3.142) we find an R-linear map, defined by linear expansion of

$$\varphi_{(S)} \ : \ S \otimes M \to N \ : \ s \otimes x \mapsto s\varphi(x)$$

Let us now prove that $\varphi \mapsto \varphi_{(S)}$ and $\psi \mapsto (x \mapsto \psi(1_S \otimes x))$ truly are mutually inverse maps (this also proves the uniqueness part of the claim). The one direction is trivial, as $\varphi_{(S)}$ has been constructed using $\varphi_S(1_S \otimes x) = \varphi(x)$. And if we start with $\psi : M_S \to N$ let us define $\varphi(x) := \psi(1_S \otimes x)$. Clearly $\varphi : M \to N$ is R-linear and we get

$$\varphi_{(S)}(s \otimes x) \ = \ s\varphi_{(S)}(1_S \otimes x) \ = \ s\psi(1_S \otimes x)$$

$$= \quad \psi\big(s(1_S \otimes x)\big) = \psi(s \otimes x)$$

In particular $\varphi \mapsto \varphi_{(S)}$ is bijective, but this map also is R-linear, as we may easily compute $(\varphi + \varphi')_{(S)}(s \otimes x) = s(\varphi + \varphi')(x) = s(\varphi(x) + \varphi'(x)) = s\varphi(x) + s\varphi'(x) = \varphi_{(S)}(s \otimes x) + \varphi'_{(S)}(s \otimes x)$ and for $a \in R$ also $(a\varphi)_{(S)}(s \otimes x) = s(a\varphi(x)) = a(s\varphi(x)) = a\varphi_{(S)}(s \otimes x)$. And if S is commutative then for r, $s \in S$ we may also compute $(r\varphi)_{(S)}(s \otimes x) = s(r\varphi(x)) = (sr)\varphi(x) = (rs)\varphi(x) = r(s\varphi(x)) = r\varphi_{(S)}(s \otimes x)$. So in this case $\varphi_{(S)}$ even is S-linear.

(vii) As in particular A is an R-module and B is an S-module we have already seen in (iv), that $\varphi_{(S)} : A \to B$ is a well-defined, S-linear map. It remains to verify the multiplicativity of $\varphi_{(S)}$. But due to the S-linearity it suffices to do this on the generating set of pure tensors:

$$\begin{aligned}
\varphi_{(S)}\big((r \otimes x)(s \otimes y)\big) &= \varphi_{(S)}\big((rs) \otimes (xy)\big) \;=\; (rs)\varphi(xy) \\
&= r(s\varphi(xy)) \;=\; r\big(s(\varphi(x)\varphi(y))\big) \\
&= r\big(\varphi(x)(s\varphi(y))\big) \;=\; (r\varphi(x))(s\varphi(y)) \\
&= \varphi_{(S)}(r \otimes x)\varphi_{(S)}(s \otimes y)
\end{aligned}$$

And if A and B both contain an unit element and φ is a homomorphism of R-algebras [that is $\varphi(1_A) = 1_B$] we find that $\varphi_{(S)}(1_S \otimes 1_A) = 1_S\varphi(1_A) = 1_S 1_B = 1_B$. As $1_S \otimes 1_A$ is the unit element of A_S this also proves that $\varphi_{(S)}$ is a homomorphism of S-algebras.

(v) Let us abbreviate the R-module $M := M(1) \otimes_R \ldots \otimes_R M(n)$ and the N-module $N := M(1)_S \otimes_S \ldots \otimes_S M(n)_S$. Then we need to show the isomorphy $M_S \xrightarrow{\sim} N$. To do this we stert with the following R-multilinear map

$$\prod_{i=1}^{n} M(i) \to N \;:\; (x_1, \ldots, x_n) \mapsto (1_S \otimes x_1) \otimes \ldots \otimes (1_S \otimes x_n)$$

Due to the multilinearity and the universal property of tensor products this map induces an R-linear map η, which is of the form

$$\eta \;:\; M \to N \;:\; x_1 \otimes \ldots \otimes x_n \mapsto (1_S \otimes x_1) \otimes \ldots \otimes (1_S \otimes x_n)$$

That is we have to show that $\eta_{(S)} : M_S \to N$ truly is an isomorphism of S-modules. And to do this we will construct the inverse map: first of all take a look at the product map $S^n \to S : (s_1, \ldots, s_n) \mapsto \prod_i s_i$. This map clearly is S-multilinear and hence induces an S-linear map

$$\mu \;:\; S^{\otimes n} \to S \;:\; s_1 \otimes s_n \mapsto \prod_{i=1}^{n} s_i$$

We will now compose the tensor mapping $\tau : M(1)_S \times \cdots \times M(n)_S \to M(1)_S \otimes_R \ldots \otimes_R M(n)_S$ and the isomorphy of the associativity of the tensor product (3.144.(ii)) $M(1)_S \otimes_R \ldots \otimes_R M(n)_S \xrightarrow{\sim} S^n \otimes_R M$ with $\mu \otimes M : S^n \otimes_R M \to S \otimes_R M$ to finally find the following map

$$M(1)_S \times \cdots \times M(n)_S \to S \otimes_R M$$

$$(s_1 \otimes x_1, \ldots, s_n \otimes x_n) \mapsto \left(\prod_{i=1}^{n} s_i\right) \otimes (x_1 \otimes \ldots \otimes x_n)$$

Looking at the explicit definition of this map it is clear that it is S-multilinear and thereby induces an S-linear map $\pi : N \to M_S$, by S-linear expansion of

$$\pi \ : \ (s_1 \otimes x_1) \otimes \ldots \otimes (s_n \otimes x_n) \mapsto \left(\prod_{i=1}^{n} s_i\right) \otimes (x_1 \otimes \ldots \otimes x_n)$$

From the explicit construction of this map it is clear, that π is the inverse of $\eta_{(S)} : 1_S \otimes (x_1 \otimes \ldots \otimes x_n) \mapsto (1_S \otimes x_1) \otimes \ldots \otimes (1_S \otimes x_n)$. Hence $\eta_{(S)}$ is bijective, that is an isomorphism of S-modules.

□

Proof of (3.161):

(iii) Let $\{ u_i \mid i \in I \} \subseteq U$ be an E-basis of $\mathsf{kn}(\varphi)$ and $\{ v_j \mid j \in J \} \subseteq V$ be an E-basis of $\mathsf{im}(\varphi)$. For any $i \in J$ we pick up some $x_j \in U$ such that $\varphi(x_j) = v_j$. Hence $\{ u_i \mid i \in I \} \cup \{ x_j \in j \in J \}$ is an E-basis of U due to the first isomorphism theorem

$$U \Big/ _{\mathsf{kn}(\varphi)} \ \xrightarrow{\sim} ; \mathsf{im}(\varphi) \ : \ x + \mathsf{kn}(\varphi) \mapsto \varphi(x)$$

To see this consider some $x \in U$, then $\varphi(x) = \sum_j b_j v_j = \sum_j b_j \varphi(x_j) = \varphi(\sum_j b_j x_j)$ for some uniquely determined $b_j \in E$. But this implies $\varphi(u - \sum_j b_j x_j) = 0$ such that $u - \sum_j b_j x_j \in \mathsf{kn}(\varphi)$. Therefore there are uniquely determined $a_i \in E$ such that $u - \sum_j b_j x_j = \sum_i a_i u_i$. Altogether we have found a unique linear combination of any $x \in U$, which means that $\{ u_i \mid i \in I \} \cup \{ x_j \in j \in J \}$ is an E-basis of U. And according to (3.160.(i)) we find that $\{ 1_S \otimes u_i \mid i \in I \} \cup \{ 1_S \otimes x_j \in j \in J \}$ is an S-basis of U_S. But it is clear, that

$$\begin{aligned} \varphi_S(1_S \otimes u_i) &= 1_S \otimes \varphi(u_i) = 0 \\ \varphi_S(1_S \otimes x_j) &= 1_S \otimes \varphi(x_f) = 1_S \otimes v_j \end{aligned}$$

In particular $\mathsf{im}(\varphi_S) = \varphi_S(U_S) = \mathsf{Lh}_S\{ 1_S \otimes v_j \mid j \in J \}$. And as the set $\{ 1_S \otimes v_j \mid j \in J \}$ is a basis, it is a S-linear independent set that generates $\mathsf{im}(\varphi_S)$, hence a S-basis.

(ii) We continue with the reasoning of (iii) above: Since $\{ 1_S \otimes u_i \mid i \in I \}$ is part of an S-basis of U_S, as well, it has to be S-linearly independent. Now consider any $u_S \in \mathsf{kn}(\varphi_S) \subseteq U_S$. Then we can write u_S in the following form

$$u_S = \sum_{i \in I} a_i 1_S \otimes u_i + \sum_{j \in J} b_j 1_S \otimes x_j$$

for some (uniquely determined) a_i and $b_j \in S$. By applying φ_S to this equation we find $0 = \varphi_S(u_s) = \sum_{j \in J} b_j 1_S \otimes v_j$. And as the $1_S \otimes v_j$ are S-linearly independent, this means $b_j = 0$ for any $j \in J$. That is $u_S = \sum_{i \in I} a_i 1_S \otimes u_i$ and as u_S has been chosen arbitarily, this means:

$$\mathsf{kn}(\varphi_S) = \mathsf{Lh}_S\{ 1_S \otimes u_i \mid i \in I \}$$

That is the set $\{ 1_S \otimes u_i \mid i \in I \}$ is an S-linearly independent set, that generates $\mathrm{kn}(\varphi_S)$, hence a basis.

(i) Since φ_S is injective if and only if $\mathrm{kn}(\varphi_S) = 0$, which according to (ii) is equivalent to $\mathrm{kn}(\varphi) = 0$, which in turn is equivalent to φ being injective, we have proved the equivalence of injectivity.

And as φ_S is surjective if and only if $\mathrm{im}(\varphi_S) = V_S$, which according to (iii) is equivalent to $\mathrm{im}(\varphi) = V$, which in turn is equivalent to φ being surjective, we have proved the equivalence of surjectivity, as well.

(iv) By definition the rank of a linear map is the dimension of the image of the map. Now in (iii) we have seen, that $\mathrm{im}(\varphi)$ and $\mathrm{im}(\varphi_S)$ both have bases of the common cardinality $|J|$. In particular, they share the same dimension $|J|$.

□

Proof of (3.159):
The first three isomorphies have been proved in (3.146) already. Also note that the proof of the remaining two isomorphies requires the use of (3.160) which has been proved right before these assertions here.
Polynomials: Clearly $\{ t^\alpha \mid \alpha \in A \}$ is an R-basis of $R[t \mid A]$ such that by (3.160.(i)) $\{ 1_S \otimes t^\alpha \mid \alpha \in A \}$ is an S-basis of $R[t \mid A]_S$. But $\{ t^\alpha \mid \alpha \in A \}$ also is an S-basis of $S[t \mid A]$, so we may define the following isomorphy of S-modules, by S-linear expansion from the basis

$$\Phi \ : \ S\,[t \mid A] \ \xrightarrow{\sim} \ S\,[t \mid A]_S \ : \ t^\alpha \mapsto 1_S \otimes t^\alpha$$

It remains to prove that Φ already is an isomorphism of S-algebras, so we have to verify its multiplicativity. Due to the S-linearity it suffices to check this for baisis elements. So compute

$$\Phi(t^\alpha t^\beta) = \Phi(t^{\alpha+\beta}) = 1_S \otimes t^{\alpha+\beta} = 1_S \otimes (t^\alpha t^\beta) = (1_S \otimes t^\alpha) \cdot (1_S \otimes t^\beta)$$

Matrices: Let us abbreviate $M := \mathrm{mat}_{m,n}(R)$ and $N := \mathrm{mat}_{m,n}(S)$. Then the R-module M has the Euclidean basis $\{ E_{i,j}(R) \mid i \in 1 \ldots m, j \in 1 \ldots n \}$ of elementary matrices $E_{i,j}(R)$. That is the (i,j)-th entry of $E_{i,j}(R)$ is 1_R all others are zero. Likewise N has the basis $\{ E_{i,j}(S) \mid i \in 1 \ldots m, j \in 1 \ldots n \}$ only that the (i,j)-th entry of $E_{i,j}(S)$ is 1_S. Now regard the canonical map

$$\iota \ : \ M \to N \ : \ (a_{i,j}) \mapsto (a_{i,j} 1_S)$$

Beware that ι need *not* be injective. Nevertheless, according to (3.160.(v)), we obtain a well-defined map $\iota_{(S)}$, which is defined by linear expansion of

$$\iota_{(S)} \ : \ M_S \to N \ : \ s \otimes A \mapsto s\iota(A)$$

And from this we clearly see that $\iota_{(S)}(1_S \otimes E_{i,j}(R)) = E_{i,j}(S)$. But by (3.160.(i)) M_S has the S-basis $\{ 1_S \otimes E_{i,j}(R) \mid i \in 1 \ldots m, j \in 1 \ldots n \}$. So $\iota_{(S)}$ matches the S-bases of M_S and N and hence is bijective and S-linear. But according to (3.160.(vi)) $\iota_{(S)}$ even is a homomorphism of S-algebras. In short: $\iota_{(S)}$ is the isomorphism we sought. □

Proof of (3.162):

Let us abbreviate $H_R := \mathrm{mhom}_R(M,N)$ and $H_S := \mathrm{mhom}_S(M_S,N_S)$. Clearly $S \times H_R \to H_S : (s,\varphi) \mapsto s\varphi_S$ is R-bilinear and hence induces the R-module-homomorphism $\mu : S \otimes H_R \to H_S$ by linear expansion of $\mu : s \otimes \varphi \mapsto s\varphi_S$. This map obviously not only is R-linear, but S-linear, as well. So it remains to verify the properties of this map given in the claim:

(i) If S is free with basis $\{ s_i \mid i \in I \}$ then according to (3.146.(iv)) we find the an isomorphy of R-modules $\Phi_M : M^{\oplus I} \xrightarrow{\sim} M_S$. And likewise we find $\Phi_N : N^{\oplus I} \xrightarrow{\sim} N_S$ and also

$$\Phi_H \ : \ H_R^{\oplus I} \ \xrightarrow{\sim} \ \big(H_R\big)_S \ : \ (\varphi_i) \mapsto \sum_{i\in I} s_i \otimes \varphi_i$$

On the other hand composing the isomorphy $H_S \xrightarrow{\sim} \mathrm{mhom}_R(M,N_S)$ that has been estabilshed in (3.160.(v)) $\psi \mapsto (x \mapsto \psi(1_S \otimes x))$ with the isomorphy $\Phi_N : N^{\oplus I} \xrightarrow{\sim} N_S$ we end up with the following isomorphy of R-modules

$$H_S \ \xrightarrow{\sim} \ \mathrm{mhom}_R(M,N^{\oplus I}) \ : \ \psi \mapsto \big(x \mapsto \Phi_N^{-1}\psi(1_S \otimes x)\big)$$

Now regard the map $\kappa : H_R^{\oplus I} \hookrightarrow \mathrm{mhom}_R(M,N^{\oplus I})$ which is defined by $(\varphi_i) \mapsto (x \mapsto (\varphi_i(x)))$. This map obviously is injective such that we end up with the following diagram

$$\begin{array}{ccc} \big(\mathrm{mhom}_R(M,N)\big)_S & \xrightarrow{\mu} & \mathrm{mhom}_S(M_S,N_S) \\ \updownarrow & & \updownarrow \\ \updownarrow & & \mathrm{mhom}_R(M,N_S) \\ \updownarrow & & \updownarrow \\ \mathrm{mhom}_R(M,N)^{\oplus I} & \xrightarrow{\kappa} & \mathrm{mhom}_R(M,N^{\oplus I}) \end{array}$$

It remains to prove that this diagram is truly commutative, then the injectivity of κ is transfered to ι. So let us start with some family $(\varphi_i) \in \mathrm{mhom}_R(M,N)^{\oplus I}$. Under κ this is transferred to $x \mapsto (\varphi_i(x))$ And $\Phi_N : N^{\oplus I} \to N_S$ drops it on

$$\left(x \mapsto \sum_{i\in I} s_i \otimes \varphi_i(x) \right) \ \in \ \mathrm{mhom}_R(M,N_S)$$

On the other hand (φ_i) is transferred upward to $\varphi = \sum_i s_i \otimes \varphi_i$ under Φ_H. From there μ transfers it to $\psi = \sum_i s_i(\varphi_i)_S$. Note that

$$\begin{aligned} \psi(1_S \otimes x) &= \sum_{i\in I} s_i(\varphi_i)_S(1_S \otimes x) \\ &= \sum_{i\in I} s_i(1_S \otimes \varphi_i(x)) \ = \ \sum_{i\in I} s_i \otimes \varphi_i(x) \end{aligned}$$

Now ψ is transported down to $\mathrm{mhom}_R(M,N_S)$ where it is turned into $x \mapsto \psi(1_S \otimes x) = \sum_i s_i \otimes \varphi_i(x)$. Thus the upper way delivers (φ_i) to exactly the same element of $\mathrm{mhom}_R(M,N_S)$ as the lower way. That is the diagram truly is commutative.

(ii) We continue with (i) but now have that I is finite. In this case the injective map κ even is bijective, according to (3.37) such that μ is bijective, as well.

(iii) Let $\{ m_j \mid j \in 1 \dots n \}$ be an R-basis of M, being an R-basis means that the map $\Phi_M : R^n \to M : (a_j) \mapsto \sum_j a_j m_j$ is an isomorphism of R-modules. Likewise if $\{ n_i \mid i \in 1 \dots m \}$ is an R-basis of N, then $\Phi_N : R^m \to N : (b_i) \mapsto \sum_i b_i n_i$ is an isomorphism as well. We now use the isomorphy of the R-module of module-homomorphisms with the R-module of $(n \times m)$-matrices over R, which is given to be

$$\chi \ : \ \mathrm{mat}_{n,m}(R) \ \xrightarrow{\sim} \ \mathrm{mhom}_R(M,N) \ : \ A \mapsto (x \mapsto \Phi_N A \Phi_M^{-1})$$

Then $\chi_S = S \otimes \chi : (\mathrm{mat}_{n,m}(R))_S \xrightarrow{\sim} (\mathrm{mhom}_R(M,N))_S$ is an isomorphism of R-modules, according to (3.149.(iii)). But as (by definition) $\chi_S : s \otimes A \mapsto s \otimes \chi(A)$ it is clear, that this map also is S-linear. But from example (3.159) we know that $(\mathrm{mat}_{n,m}(R))_S$ is isomorphic (as an S-module) to $\mathrm{mat}_{n,m}(S)$ under the isomorphism $s \otimes A \mapsto sA$. And using the same reasoning as for the homomorphisms $M \to N$ we find that $\mathrm{mat}_{n,m}(S) \xrightarrow{\sim} \mathrm{mhom}_S(M_S, N_S)$ where we use the induced bases $\{ 1_S \otimes m_j \mid j \in 1 \dots n \}$ and $\{ 1_S \otimes n_i \mid i \in 1 \dots m \}$ again. Putting all these together we have finally arrived at the isomorphy

$$\big(\mathrm{mhom}_R(M,N)\big)_S \ \xrightarrow{\sim} \ \mathrm{mhom}_S(M_S, M_S)$$

Let us regard how this isomorphy works: if we start with some $s \in S$ and some homomorphism $\varphi : M \to N$ then χ_S^{-1} maps $s \otimes \varphi$ to $s \otimes A$ where A is the matrix of φ that is $\chi(A) = \varphi$. This is then taken to the matrix sA which represents the homomorphism $s\varphi_S : M_S \to N_S$ by (3.160.(ii)). So altogether we have verified that truly $s \otimes \varphi \mapsto s\varphi_S$ as has been claimed.

□

Proof of (3.155):

(i) If M and N are finitely generated, say $M = \mathrm{Lh}\{ x_i \mid i \in 1 \dots m \}$ and $N = \mathrm{Lh}\{ y_j \mid j \in 1 \dots n \}$, then any $x \in M$ and any $y \in N$ can be written in the form $x = \sum_i a_i x_i$ and $y = \sum_j b_j y_j$ respectively. But this means, that the tensor $x \otimes y$ can be written as

$$x \otimes y \ = \ \sum_{i=1}^{m} \sum_{j=1}^{n} a_i b_j \, x_i \otimes y_j$$

That is any pure tensor $x \otimes y$ can be generated by the mn (finitely many) elements $\{ x_i \otimes y_j \mid i \in 1 \dots m, \ j \in 1 \dots$ And as any $t \in M \otimes M$ is a sum of pure tensors, this means that any t can be generated over these mn elements. In particular $M \otimes N$ is finitely generated.

(i) Let $\star$ abbreviate one of the words *noetherian* or *artinian*. As M is finitely generated there is a surjective homomorphism $\mu : R^m \twoheadrightarrow M$: Pick up a generating set $\{ x_i \mid i \in 1 \dots m \}$ of M then μ can be given explicitly to be $\mu(a_1, \dots, a_m) = \sum_i a_i x_i$. But according to (3.149.(iii)) we thereby find that $\mu \otimes N : R^m \otimes N \twoheadrightarrow M \otimes N$ is another surjective homomorphism of R-modules.

On the other hand proposition (3.146.(v)) tells us that there is an isomorphy $R^m \otimes N \ \cong_{\mathrm{m}} \ N^m$. Thereby N^m is a $\star$ module, since N is $\star$ and hence is its power, due to (3.111.(iv)) This of course means, that $R^m \otimes N$ is a $\star$ module again.

But since $M \otimes N = \mathrm{im}(\mu \otimes N)$ is the image of the $\star$ module $R^m \otimes N$ under the surjective homomprphism $\mu \otimes N$ theorem (3.111.(v)) finally tells us, that $M \otimes N$ is $\star$. as well.

(ii) If M and N are finitely generated, then so is $M \otimes N$, according to (i). And if M and N are free, then so is $M \otimes N$ according to (3.146.(vi)). Now if M and N are noetherian, then in particular M is finitely generated. Hence $M \otimes N$ is noetherian, according to (i) again. If M and N are artinian, then $M \otimes N$ is a module of finite length, as we have seen in (3.120) and in particular $M \otimes N$ is an artinian module again, due to (3.119.(vi)).

(iii) If both M and N are of finite length, then let us regard a composition series of M, that is $0 = M_0 \subset M_1 \subset M_2 \subset \ldots \subset M_p = M$ where $p = \ell(M)$ and any M_k/M_{k-1} is a simple R-module. That is there are some $m_i \in M$ such that $M_i = M_{i-1} + Rm_i$ and in particular M is finitely generated by the elements $\{ m_1, \ldots, m_p \}$.

Thus we find a surjective map $\mu : R^p \twoheadrightarrow M : (a_1, \ldots, a_p) \mapsto \sum_i a_i m_i$. Tensoring this with N we maintain the surjectivity of the homomorphism $\mu \otimes N : R^p \otimes N \twoheadrightarrow M \otimes N$. And thereby $N^p \cong_{\mathfrak{m}} R^p \otimes N$ are isomorphic by (3.146.(v)) again.

According to the Jordan-Hölder theorem (check the remark following it) N^p has finite length $\ell(N^p) = \ell(N^{\oplus p}) = p \cdot \ell(N) = \ell(M) \cdot \ell(N)$. And as $\mu \otimes N$ is surjective and $R^p \otimes N$ has finite length, so does $M \otimes N$. To be precise we find the claim

$$\ell(M \otimes N) \;\leq\; \ell(R^p \otimes N) \;=\; \ell(N^p) \;=\; \ell(M) \cdot \ell(N)$$

(iv) Pick up any R-module N and denote the R-module of R-linear maps from $M \to N$ by $H := \mathcal{L}(M, N)$. Then by assumption and (3.93) we find the following exact chain of R-modules

$$0 \to \mathcal{L}(W, H) \xrightarrow{\psi^*} \mathcal{L}(V, H) \xrightarrow{\varphi^*} \mathcal{L}(U, H)$$

Recall that $H = \mathcal{L}(M, N)$ is another module of homomorphisms and hence we have the isomorphy $\mathcal{L}(W \otimes M, N) \xrightarrow{\sim} \mathcal{L}(W, H) : \gamma \mapsto \gamma'$ where $\gamma'(w)(m) = \beta(w \otimes m)$ according to (the remark following) (3.142). That is we have arrived at the following diagram of R-module homomorphisms [where we abbreviated $W_M := W \otimes M$ and $\psi_M := \psi \otimes \mathbb{1}_M$ and so on for notational reasons. The vertical homomorphisms are the isomorphies $\sigma \mapsto \gamma'$ and $\beta \mapsto \beta'$ respectively]

$$\begin{array}{ccccccc}
0 & \to & \mathcal{L}(W, H) & \xrightarrow{\psi^*} & \mathcal{L}(V, H) & \xrightarrow{\varphi^*} & \mathcal{L}(U, H) \\
 & & \updownarrow & & \updownarrow & & \updownarrow \\
0 & \to & \mathcal{L}(W_M, N) & \xrightarrow{\psi_M^*} & \mathcal{L}(V_M, N) & \xrightarrow{\varphi_M^*} & \mathcal{L}(U_M, N)
\end{array}$$

Next we will prove that this diagram commutes: Let us start with $\gamma \in \mathcal{L}(W \otimes M, N)$. On the bottom line we get for any $v \in V$ and any $m \in N$ that $(\psi \otimes M)^*(\gamma)(v \otimes m) = \gamma \circ (\psi \otimes M)(v \otimes m) = \gamma(\psi(v) \otimes m)$. But this is precisely the same, as $(\psi^*(\gamma'))(v)(m) = ((\gamma'\psi)(v))(m) = \gamma'(\psi(v))(m) = \gamma(\psi(v) \otimes m)$. In complete analogy we see the commutativity of the second (left) square, if we start with some $\beta \in \mathcal{L}(V \otimes M, N)$.

Due to the commutativity of the diagram the bottom line inherits the exactness form the top line, according to (3.92). But as the module N can be chosen arbitrarily the lemma of Yoneda (3.94.(ii))

tells us that the following chain of R-modules truly is exact, as claimed

$$U \otimes M \overset{\varphi \otimes M}{\longrightarrow} V \otimes M \overset{\psi \otimes M}{\longrightarrow} W \otimes M \to 0$$

(v) The inclusion $\mathrm{im}(\varphi_1 \otimes N_1) + \mathrm{im}(M_1 \otimes \psi_1) \subseteq \mathrm{kn}(\varphi_2 \otimes \psi_2)$ is easy to see: due to the composition properties of the tensor product of maps we have

$$(\varphi_2 \otimes \psi_2)(\varphi_1 \otimes N_1) \;=\; \varphi_2\varphi_1 \otimes \varphi_1 \;=\; 0 \otimes \varphi_1 \;=\; 0$$

such that $\mathrm{im}(\varphi_1 \otimes N_1) \subseteq \mathrm{kn}(\varphi_2 \otimes \psi_2)$. Likewise we find $\mathrm{im}(M_1 \otimes \psi_1) \subseteq \mathrm{kn}(\varphi_2 \otimes \psi_2)$ and hence the sum is contained in the kernel, as well.

For the converse inclusion $\mathrm{kn}(\varphi_2 \otimes \psi_2) \subseteq \mathrm{im}(\varphi_1 \otimes N_1) + \mathrm{im}(M_1 \otimes \psi_1)$ we note in advance that according to (iv) for any $k \in 0 \ldots 2$ the following chain of R-modules is exact

$$M_0 \otimes N_k \overset{\varphi_1 \otimes N_k}{\longrightarrow} M_1 \otimes N_k \overset{\varphi_2 \otimes N_k}{\longrightarrow} M_2 \otimes N_k \to 0$$

and in particular $\mathrm{kn}(\varphi_2 \otimes N_k) = \mathrm{im}(\varphi_1 \otimes N_k)$. Likewise it is clear, that for any $i \in 0 \ldots 2$ we also have $\mathrm{kn}(M_i \otimes \psi_2) = \mathrm{im}(M_i \otimes \psi_1)$. We will use these equalities several times.

Now consider any $t \in \mathrm{kn}(\varphi_2 \otimes \psi_2) \subseteq M_1 \otimes N_1$, then we need to prove $t \in \mathrm{im}(\varphi_1 \otimes N_1) + \mathrm{im}(M_1 \otimes \psi_1)$. But first of all we may compute

$$0 \;=\; (\varphi_2 \otimes \psi_2)(t) \;=\; (\varphi_2 \otimes N_2)(M_1 \otimes \psi_2)(t)$$

and hence we find $(M_1 \otimes \psi_2)(t) \in \mathrm{kn}(\varphi_2 \otimes N_2) = \mathrm{im}(\varphi_1 \otimes N_2)$. That is there is some $q \in M_0 \otimes N_2$ such that

$$(\varphi_1 \otimes N_2)(q) \;=\; (M_1 \otimes \psi_2)(t)$$

Also, as ψ_2 is surjective, so is $M_0 \otimes \psi_2 : M_0 \otimes N_1 \to M_0 \otimes N_2$ and hence there is some $p \in M_0 \otimes N_1$ such that $q = (M_0 \otimes \psi_2)(p)$. Now $(\varphi_1 \otimes \psi_2)(p) = (\varphi_1 \otimes N_2)(M_0 \otimes \psi_2)(p) = (\varphi_1 \otimes N_2)(q) = (M_1 \otimes \psi_2)(t)$ or equivalently

$$\begin{aligned} 0 &= (M_1 \otimes \psi_2)(t) - (\varphi_1 \otimes \psi_2)(p) \\ &= (M_1 \otimes \psi_2)(t) - (M_1 \otimes \psi_2)(\varphi_1 \otimes N_1)(p) \\ &= (M_1 \otimes \psi_2)\Big(t - (\varphi_1 \otimes N_1)(p)\Big) \end{aligned}$$

This implies $t - (\varphi_1 \otimes N_1)(p) \in \mathrm{kn}(M_1 \otimes \psi_2) = \mathrm{im}(M_1 \otimes \psi_1)$. That is there is some $p' \in M_1 \otimes N_0$ such that $t - (\varphi_1 \otimes N_1)(p) \;=\; (M_1 \otimes \psi_1)(p')$. So altogether we found

$$t \;=\; (\varphi_1 \otimes N_1)(p) + (M_1 \otimes \psi_1)(p') \;\in\; \mathrm{im}(\varphi_1 \otimes N_1) + \mathrm{im}(M_1 \otimes \psi_1)$$

(ii) Now assume that both M an N have a finite free presentation, that is there are exect chains of R-modules of the following form

$$R^p \;\overset{\varphi}{\longrightarrow}\; R^m \;\overset{\mu}{\longrightarrow}\; M \;\to\; 0$$

$$R^q \xrightarrow{\varphi} R^n \xrightarrow{\nu} N \to 0$$

Since both μ and ν are surjective, so is $\mu \otimes \nu$ and hence we find the following exact chain of R-modules

$$R^m \otimes R^n \xrightarrow{\mu \otimes \nu} M \otimes N \to 0$$

Note that $R^m \otimes R^n$ is isomorphic to R^{mn} and hence we already have a candidate for the end of our finite free presentation of $M \otimes N$. Also by (v) we explicitly know the kernel of $\mu \otimes \nu$ to be

$$\mathrm{kn}(\mu \otimes \nu) = \mathrm{im}(\varphi \otimes R^n) + \mathrm{im}(R^m \otimes \psi)$$

In particular we see, that the kernel is finitely generated again: Let e_1 to e_p be a basis of R^p and f_1 to f_q be a basis of R^q. Then we see that the kernel of $\mu \otimes \nu$ is precisely given to be the linear hull of

$$\begin{aligned} \mathrm{kn}(\mu \otimes \nu) &= \mathrm{Lh}\{\, \varphi(e_i) \otimes f_k \mid i \in 1 \ldots p,\, k \in 1 \ldots q \,\} \\ &\quad + \mathrm{Lh}\{\, e_j \otimes \psi(f_\ell) \mid j \in 1 \ldots p,\, \ell \in 1 \ldots q \,\} \end{aligned}$$

Hence we let $N := p \cdot n + m \cdot q$ and take $\kappa : R^N \to R^m \otimes R^n$ to be the R-linear map that gives a linear expansion of these generators

$$\kappa(a_{i,k}, b_{j,\ell}) := \sum_{i=1}^{p} \sum_{k=1}^{q} a_{i,k}\, \varphi(e_i) \otimes f_k + \sum_{j=1}^{p} \sum_{\ell=1}^{q} b_{j,\ell}\, e_j \otimes \psi(f_\ell)$$

then by construction the image of κ is precisely the kernel of $\mu \otimes \nu$. And thereby we have found a finite free presentation of $M \otimes N$

$$R^N \xrightarrow{\kappa} R^m \otimes R^n \xrightarrow{\mu \otimes \nu} M \to 0$$

□

Proof of (3.153):
If the m_i and n_j satisfy these properties, it is easy to compute, that their tensor product truly vanishes

$$\begin{aligned} \sum_{j \in J} m_j \otimes n_j &= \sum_{j \in J} \left(\sum_{i=1}^{m} a_{i,j} x_j \right) \otimes n_j = \sum_{j \in J} \sum_{i=1}^{m} a_{i,j} x_j \otimes n_j \\ &= \sum_{i=1}^{m} x_j \otimes \left(\sum_{j \in J} a_{i,j} n_j \right) = \sum_{i=1}^{m} x_j \otimes 0 = 0 \end{aligned}$$

Conversely we assume the tensor to be zero and want to show that all these $x_i \in M$ and $a_{i,j} \in R$ exist and satisfy the properties required of them. Since $\{\, n_j \mid j \in J \,\}$ generates N the map $\nu : R^{\oplus J} \to N$ defined by $\nu(b) = \sum_j b_j n_j$ is surjective. Hence we get a short exact chain of R-modules

$$0 \to \mathrm{kn}(\nu) \xrightarrow{\subseteq} R^{\oplus J} \xrightarrow{\nu} N \to 0$$

And according to (3.155.(iv)) we thereby get another exact chain of R-modules by tensoring with M

$$M \otimes \mathrm{kn}(\nu) \overset{M\otimes \subseteq}{\longrightarrow} M \otimes R^{\oplus J} \overset{M\otimes \nu}{\longrightarrow} M \otimes N \to 0$$

Let $\left\{ e_j \mid j \in J \right\}$ be the standard Euclidean basis of $R^{\oplus J}$ then $\nu(e_j) = n_j$ and hence we find $(M \otimes \nu)(\sum_j m_j \otimes e_j) = \sum_j m_j \otimes n_j = 0$ by assumption, such that $\sum_j m_j \otimes e_j \in \mathrm{kn}(M \otimes \nu) = \mathrm{im}(M\otimes \subseteq)$. That is there is some $\sum_i x_i \otimes k_i \in M \otimes \mathrm{kn}(\nu)$ such that

$$\sum_{i=1}^{m} x_i \otimes k_i \;=\; (M\otimes \subseteq) \left(\sum_{i=1}^{m} x_i \otimes k_i \right) \;=\; \sum_{j\in J} m_j \otimes e_j$$

Now write $k_i \in \mathrm{kn}(\nu) \subseteq R^{\oplus J}$ as $k_i = \sum_j a_{i,j} e_j$ [which is possible, as the e_j form a basis of $R^{\oplus J}$], then clearly

$$0 \;=\; \nu(k_i) \;=\; \sum_{j\in J} a_{i,j} \nu(e_j) \;=\; \sum_{j\in J} a_{i,j} n_j$$

for any $i \in 1 \ldots m$ and this already is the first property. For the second property we compute

$$\begin{aligned} \sum_{j\in J} m_j \otimes e_j \;&=\; \sum_{i=1}^{m} x_i \otimes k_i \;=\; \sum_{i=1}^{m} x_i \otimes \left(\sum_{j\in J} a_{i,j} e_j \right) \\ &=\; \sum_{j\in J} \left(\sum_{i=1}^{m} a_{i,j} x_i \right) \otimes e_j \end{aligned}$$

Recall that by (3.146.(v)) we have the isomorphy $M^{\oplus J} \overset{\sim}{\longrightarrow} M \otimes R^{\oplus J}$ given by $(m_j) \mapsto \sum_j m_j \otimes e_j$. That is the above sums are identical images under this isomorphism and hence their preimages are equal as well. This is the second property - for any $j \in J$ we get

$$m_j \;=\; \sum_{i=1}^{m} a_{i,j} x_i$$

□

Proof of (3.139):

(i) By definition the support of M is empty iff we have $M_\mathfrak{p} = 0$ for any $\mathfrak{p} \in \mathrm{Spec}(R)$. So this is property (b) in (3.135). So the claim is just a reformulation of (a) $\iff$ (b) in said proposition.

(ii) Let $P := 0$, then for any $\mathfrak{p} \in \mathrm{Spec}(R)$ we clearly have $P_\mathfrak{p} = 0$, as well. So by (3.136) we have the equivalence of

$$x = 0 \quad\iff\quad \forall\, \mathfrak{m} \in \mathrm{Smax}(R) \,:\, \frac{x}{1} = \frac{0}{1}$$

for any $x \in M$. As $\mathrm{Smax}(R) \subseteq \mathrm{Spec}(R)$ we get the same equivalence with the prime instead od the maximal spectrum. But if $\mathfrak{p} \in \mathrm{Spec}(R)$ is prime, but $\mathfrak{p} \notin \mathrm{Supp}(M)$, then $P_\mathfrak{p} \subseteq M_\mathfrak{p} = 0$ such that $x/1 = 0/1$ anyhow. That is these $\mathfrak{p}$ do not contribute to the truth of the statement and hence

$$x = 0 \quad\iff\quad \forall\, \mathfrak{p} \in \mathrm{Supp}(R) \,:\, \frac{x}{1} = \frac{0}{1}$$

But this is the (well-definedness) and injectivity of the endomorphism given in the claim. And the

homomorphism property is trivial.

(iii) Consider some $\mathfrak{p} \notin \mathbb{V}(\mathfrak{a})$, that is there is some $a \in \mathfrak{a}$ such that $a \notin \mathfrak{p}$. That is $a \in U := R \setminus \mathfrak{p}$ is contained in the multiplicatively closed set of the localization. Thus for any $(b+\mathfrak{a})/u \in (R/\mathfrak{a})_\mathfrak{p}$ we have

$$a\frac{b+\mathfrak{a}}{u} \;=\; \frac{ab+\mathfrak{a}}{u} \;=\; \frac{0+\mathfrak{a}}{u} \;=\; a\frac{0+\mathfrak{a}}{1} \;=\; 0$$

That is for any $x = (b+\mathfrak{a})/u \in (R/\mathfrak{a})_\mathfrak{p}$ there is $a \in U$ such that $ax = 0$ and hence $(R/\mathfrak{a})_\mathfrak{p} = 0$. This means $\mathfrak{p} \notin \operatorname{Supp}(R/\mathfrak{a})$, as well.

Conversely, if $\mathfrak{p} \in \mathbb{V}(\mathfrak{a})$ then $\mathfrak{a} \subseteq \mathfrak{p}$ and thereby $\mathfrak{a}_\mathfrak{p} := U^{-1}\mathfrak{a} \subseteq \mathfrak{m}_\mathfrak{p} := U^{-1}\mathfrak{p}$. Note that $\mathfrak{m}_\mathfrak{p}$ is *the* maximal ideal of $R_\mathfrak{p}$. But by (2.132.(vi)) we also have an isomorphy of the form

$$\Big(R\Big/\mathfrak{a}\Big)_\mathfrak{p} \;\cong_\mathsf{r}\; R_\mathfrak{p}\Big/\mathfrak{a}_\mathfrak{p} \;\neq\; 0$$

In particular $(R/\mathfrak{a})_\mathfrak{p} \neq 0$ which means $\mathfrak{p} \in \operatorname{Supp}(R/\mathfrak{a})$. Together this is the equality of the subsets $\mathbb{V}(\mathfrak{a}) = \operatorname{Supp}(R/\mathfrak{a})$ of the spectrum of R.

(iv) We start with the general statement: Given a short exact chain $0 \to L \to M \to N \to 0$ of R-modules, where $\varphi : L \to M$ and $\psi : M \to N$ are the respective homomorphisms, any prime ideal $\mathfrak{p} \trianglelefteq_\mathsf{i} R$ gives rise to another short exact chain of R-modles, according to (3.126)

$$0 \;\to\; L_\mathfrak{p} \;\to\; M_\mathfrak{p} \;\to\; N_\mathfrak{p} \;\to\; 0$$

If $\mathfrak{p} \notin \operatorname{Supp}(M)$ then $M_\mathfrak{p} = 0$. As $L_\mathfrak{p} \hookrightarrow M_\mathfrak{p}$ is injective this implies $L_\mathfrak{p} = 0$ and as $M_\mathfrak{p} \twoheadrightarrow N_\mathfrak{p}$ is surjective this implies $N_\mathfrak{p} = 0$ such that $\mathfrak{p} \notin \operatorname{Supp}(L)$ and $\mathfrak{p} \notin \operatorname{Supp}(N)$. If we abbreviate $\mathcal{S} := \operatorname{Spec}(R)$ that is the inclusion

$$\mathcal{S} \setminus \operatorname{Supp}(M) \;\subseteq\; \big(\mathcal{S} \setminus \operatorname{Supp}(L)\big) \cap \big(\mathcal{S} \setminus \operatorname{Supp}(N)\big)$$

But the converse inclusion is true as well: If *both* $L_\mathfrak{p} = 0$ and $N_\mathfrak{p} = 0$ then $0 \hookrightarrow M_\mathfrak{p} \twoheadrightarrow 0$. And as $M_\mathfrak{p} = \ker(\psi_\mathfrak{p}) = \operatorname{im}(\varphi_\mathfrak{p}) = 0$ we also have $M_\mathfrak{p} = 0$ such that $\mathfrak{p} \notin \operatorname{Supp}(M)$. Now by going to complements we find the claim from the equation

$$\mathcal{S} \setminus \operatorname{Supp}(M) \;=\; \big(\mathcal{S} \setminus \operatorname{Supp}(L)\big) \cap \big(\mathcal{S} \setminus \operatorname{Supp}(N)\big) \;=\; \mathcal{S} \setminus \big(\operatorname{Supp}(L) \cup \operatorname{Supp}(N)\big)$$

Now return to the case $L = P \leq_\mathsf{m} M$ and $N = M/P$. It suffices to present the following short exact chain of R-modules: Let $\varphi := \iota : P \hookrightarrow M : x \mapsto x$ and $\psi := \varrho : M \twoheadrightarrow M/P : x \mapsto x + P$, then $\operatorname{Supp}(M)$ is the union of $\operatorname{Supp}(P)$ and $\operatorname{Supp}(M/P)$, as these give rise to the chain

$$0 \;\to\; P \;\to\; M \;\to\; M\Big/P \;\to\; 0$$

(v) Let us abbreviate $\mathcal{S} := \operatorname{Spec}(R)$ and $P := \sum_i P_i$ and consider some prime ideal $\mathfrak{p} \trianglelefteq_\mathsf{i} R$ such that $P_\mathfrak{p} = 0$. That is for any $x \in P$ there is some $u \in U := R \setminus \mathfrak{p}$ such that $ux = 0$. As any $P_i \subseteq P$ this means that $(P_i)_\mathfrak{p} = 0$, too and thereby

$$\mathcal{S} \setminus \operatorname{Supp}(P) \;\subseteq\; \mathcal{S} \setminus \operatorname{Supp}(P_i)$$

By going to complements this is $\mathrm{Supp}(P_i) \subseteq \mathrm{Supp}(P)$ for any $i \in I$. Conversely suppose $(P_i)_\mathfrak{p} = 0$ for any $i \in I$ and pick up some $x \in P$. That is there is a finite subset $\Omega \subseteq I$ and some $x_i \in P_i$ (where $i \in \Omega$) such that $x = \sum_i x_i$ (where the sum runs over $i \in \Omega$). As $(P_i)_\mathfrak{p} = 0$ there is some $u_i \in U$ such that $u_i x_i = 0$. Now let $u := \prod u_i$ (where the product runs over $i \in \Omega$), as U is multiplicatively closed we have $u \in U$ and $ux = \sum_i ux_i = \sum_i 0 = 0$ is clear. Therefore we also have the inclusion

$$\mathcal{S} \setminus \bigcup_{i\in I} \mathrm{Supp}(P_i) \;=\; \bigcap_{i\in I} \mathcal{S} \setminus \mathrm{Supp}(P_i) \;\subseteq\; \mathcal{S} \setminus \mathrm{Supp}(P)$$

By going to complements again, we also find $\bigcup_i \mathrm{Supp}(P_i) \subseteq \mathrm{Supp}(P)$, such that we have established the desired identity.

(viii) In a first step let us prove the claim for finitely generated modules M and N over a local ring S with maximal ideal $\mathfrak{m}$. Let $E := S/\mathfrak{m}$ be the quotient field of S and $M_E := E \otimes_S M$ and likewise $N_E := E \otimes_S N$. We know by (3.159) that M_E is isomorphic to $M_E \xrightarrow{\sim} M/\mathfrak{m}M$. And thereby the lemma of Nakayama (3.44.(ii)) [note that $\mathfrak{m} = \mathrm{JAC}(S)$] implies the equivalence of

$$M_E = 0 \iff M = \mathfrak{m}M \iff M = 0$$

As M_E is an E-module and E is a field, M_E is free, likewise N_E. Also by (3.160.(v)) we have an isomorphy of E-modules of the form

$$\big(M \otimes_S N\big)_E \xrightarrow{\sim} M_E \otimes_E N_E$$

In particular these modules share the same dimension. But as M_E and N_E are free (3.146.(vi)) implies the equality of the dimension

$$\dim\Big(\big(M \otimes_S N\big)_E\Big) \;=\; \dim\big(M_E \otimes_E N_E\big) \;=\; \dim\big(M_E\big) \cdot \dim\big(N_E\big)$$

That is $(M \otimes_S N)_E = 0$ is equivalent to $M_E = 0$ or $N_E = 0$. But we have already argued, that these statements are equivalent to

$$M \otimes_S N = 0 \iff M = 0 \quad \text{or} \quad N = 0$$

Let us now consider finitely generated modules M and N over an arbitrary commutative ring R. Then we would like to show the equality of the support

$$\mathrm{Supp}(M \otimes N) \;=\; \mathrm{Supp}(M) \cap \mathrm{Supp}(N)$$

So consider any prime ideal $\mathfrak{p} \trianglelefteq_\mathrm{i} R$ and let $S := R_\mathfrak{p}$ then S is a local ring with maximal ideal $\mathfrak{p}S$. And $\mathfrak{p} \notin \mathrm{Supp}(M \otimes_R N)$ iff $(M \otimes_R N)_\mathfrak{p} = 0$. But by (3.151) we have the isomorphies

$$\big(M \otimes_R N\big)_\mathfrak{p} \;\cong_\mathfrak{m}\; M_\mathfrak{p} \otimes_R N_\mathfrak{p} \;\cong_\mathfrak{m}\; \big(M_\mathfrak{p} \otimes_S N_\mathfrak{p}\big)_R$$

Hence $M \otimes_R N = 0$ is equivalent to $M_\mathfrak{p} \otimes_S N_\mathfrak{p} = 0$. But as S is a local ring, we have already argued that this again is equivalent to $M_\mathfrak{p} = 0$ or $N_\mathfrak{p} = 0$. But this is $\mathfrak{p} \notin \mathrm{Supp}(M)$ or $\mathfrak{p} \notin \mathrm{Supp}(N)$.

Negating this we find the desired equivalence

$$\mathfrak{p} \in \operatorname{Supp}(M \otimes_R N) \iff \mathfrak{p} \in \operatorname{Supp}(M) \text{ and } \mathfrak{p} \in \operatorname{Supp}(N)$$

(vi) For any $i \in I$ we have $R/\mathfrak{a}_i \xrightarrow{\sim} Rm_i : a + \mathfrak{a}_i \mapsto am_i$ according to (3.22.(ii)). Thereby $\operatorname{Supp}(Rm_i) = \operatorname{Supp}(R/\mathfrak{a}_i) = \mathbb{V}(\mathfrak{a}_i)$ due to (iii). If now $M = \operatorname{Lh}\{ m_i \mid i \in I \}$ then $M = \sum_i Rm_i$ so by (iv) we get

$$\operatorname{Supp}(M) = \bigcup_{i\in I} \operatorname{Supp}(Rm_i) = \bigcup_{i\in I} \mathbb{V}(\mathfrak{a}_i)$$

If M is finitely generated, say $I = 1 \dots n$ then $\mathfrak{a} := \operatorname{ann}(M) = \bigcap_i \mathfrak{a}_i$ and as I is finite (2.16) implies

$$\operatorname{Supp}(M) = \bigcup_{i=1}^{n} \mathbb{V}(\mathfrak{a}_i) = \mathbb{V}\left(\bigcap_{i=1}^{n} \mathfrak{a}_i\right) = \mathbb{V}(\mathfrak{a})$$

Now suppose that $\mathfrak{a} \trianglelefteq_{\mathsf{i}} R$ is an ideal of R, then by (3.146.(ii)) we have the isomorphy $(R/\mathfrak{a}) \otimes M \cong_{\mathsf{m}} M/\mathfrak{a}M$. In particular we may invoke (viii), (iii) and (2.16) to find its support

$$\begin{aligned}
\operatorname{Supp}\left(M \Big/ \mathfrak{a}M\right) &= \operatorname{Supp}\left(R \Big/ \mathfrak{a} \otimes M\right) \\
&= \operatorname{Supp}\left(R \Big/ \mathfrak{a}\right) \cap \operatorname{Supp}(M) \\
&= \mathbb{V}(\mathfrak{a}) \cap \mathbb{V}\big(\operatorname{ann}(M)\big) \\
&= \mathbb{V}\big(\mathfrak{a} + \operatorname{ann}(M)\big)
\end{aligned}$$

(vii) As M is finitely generated, we find that the intersection of all $\mathfrak{p} \in \operatorname{Supp}(M)$ is the radical of the annihilator of M, by (vi) and (2.25.(i))

$$\bigcap \operatorname{Supp}(M) = \bigcap \mathbb{V}(\operatorname{ann}(M)) = \sqrt{\operatorname{ann}(M)}$$

Therefore $a \in \bigcap \operatorname{Supp}(M)$ is equivalent to $a^n \in \operatorname{ann}(M)$ for some $n \in \mathbb{N}$. And this again means $a^n M = 0$.

Now consider a finitely generated ideal $\mathfrak{a} \trianglelefteq_{\mathsf{i}} R$. As the grand intersection reverses the order under inclusion we find that $\mathbb{V}(\operatorname{ann}(M)) = \operatorname{Supp}(M) \subseteq \mathbb{V}(\mathfrak{a})$ is equivalent, to

$$\sqrt{\mathfrak{a}} = \bigcap \mathbb{V}(\mathfrak{a}) \subseteq \bigcap \mathbb{V}(\operatorname{ann}(M)) = \sqrt{\operatorname{ann}(M)}$$

As $\mathfrak{a}$ is finitely generated $\mathfrak{a} \subseteq \sqrt{\mathfrak{a}} \subseteq \sqrt{\operatorname{ann}(M)}$ implies $\mathfrak{a}^n \subseteq \operatorname{ann}(M)$ for some $n \in \mathbb{N}$, according to (2.25.(vii)). And $\mathfrak{a}^n M = 0$ is just a reformulation of this. Conversely suppose $\mathfrak{a}^n \subseteq \operatorname{ann}(M)$ for some $n \in \mathbb{N}$. If $n = 0$ then $\operatorname{ann}(M) = R$ and hence $M = 0$. This would imply $\operatorname{Supp}(M) = \emptyset$ and in particular $\operatorname{Supp}(M) = \emptyset \subseteq \mathbb{V}(\mathfrak{a})$. Thus consider $n \geq 1$ then by (2.25.(vi)) we get $\sqrt{\mathfrak{a}} \subseteq \sqrt{\mathfrak{a}^n} \subseteq \sqrt{\operatorname{ann}(M)}$ and therefore $\operatorname{Supp}(M) \subseteq \mathbb{V}(\mathfrak{a})$.

(viii) It remains to prove the second part of the claim in (viii). By (i) we know that $M \otimes N = 0$ is equivalent to $\operatorname{Supp}(M \otimes N) = \emptyset$. But as $\operatorname{Supp}(M \otimes N) = \operatorname{Supp}(M) \cap \operatorname{Supp}(N)$ and the fact, that M and N are finitely generated, by assumption, we have $\operatorname{Supp}(M) = \mathbb{V}(\operatorname{ann}(M))$ and

$\mathrm{Supp}(N) = \mathbb{V}(\mathrm{ann}(N))$ according to (vi). That is

$$\mathrm{Supp}(M \otimes N) \;=\; \mathrm{Supp}(M) \cap \mathrm{Supp}(N) \;=\; \mathbb{V}(\mathrm{ann}(M)) \cap \mathbb{V}(\mathrm{ann}(N))$$

Yet by (2.32) this is $\mathrm{Supp}(M \otimes N) = \mathbb{V}(\mathrm{ann}(M) + \mathrm{ann}(N))$. As any proper ideal is contained in a maximal ideal and this is prime, we have $\mathrm{Supp}(M \otimes N) = \emptyset$ if and only if $\mathrm{ann}(M) + \mathrm{ann}(N) = R$.

□

Proof of (5.4):
By definition $M(q) = \{\, x \in M \mid \exists\, n \in \mathbb{N} : q^n x = 0 \,\}$. And by construction any element of M is of the form $x = (a_{i,j} + p(j)^{n(i,j)}R)$ for some $a_{i,j} \in R$. Thus $q^n x = 0$ is equivalent to $q^n a_{i,j} \in p(j)^{n(i,j)}R$ for any $j \in 1 \ldots s$ and any $i \in 1 \ldots I(j)$. This in turn is equivalent, to

$$q^n x \;=0 \quad\Longleftrightarrow\quad \forall\, j \in 1 \ldots s \;\; \forall\, i \in 1 \ldots I(j) \;:\; p(j)^{n(i,j)} \;\mid\; q^n a_{i,j}$$

As R is an UFD the divisibility $p(j)^{n(i,j)} \;\mid\; q^n a_{i,j}$ can be rewritten, as $\langle p \mid p(j)^{n(i,j)} \rangle \leq \langle p \mid q^n a_{i,j} \rangle$ for any prime element $p \in R$, according to (2.64.(iii)). But the only prime occurring in $p(j)^{n(i,j)}$ is $p(j)$ so this condition boils down, to

$$q^n x \;=0 \quad\Longleftrightarrow\quad \forall\, j \in 1 \ldots s \;\; \forall\, i \in 1 \ldots I(j) \;:\; n(i,j) \;\leq\; \langle q(j) \mid q^n a_{i,j} \rangle$$

We now distinguish two cases: If $q \approx p(k)$ then $n(i,k) \leq \langle q(k) \mid q^n a_{i,j} \rangle$ can easily be accomplished by taking $n := \max\{\, n(i,k) \mid i \in 1 \ldots I(k) \,\}$. If $q \approx p(j)$ is untrue, then $\langle p(j) \mid q^n \rangle = n \cdot \langle p(j) \mid q \rangle = 0$ such that by (2.64.(ii)) we get $n(i,j) \leq \langle p(j) \mid q^n a_{i,j} \rangle = \langle p(j) \mid q^n \rangle + \langle p(j) \mid a_{i,j} \rangle = \langle p(j) \mid a_{i,j} \rangle$. But this already is $a_{i,j} \in p(j)^{n(i,j)}R$ such that these $a_{i,j} + p(j)^{n(i,j)}$ have to be zero in the first place. This proved two things: (1) If $q \approx p(k)$ then $M(q)$ consists precisely of those x that can be written with $a_{i,j} = 0$ for any $j \neq k$ and (2) if $q \approx p(j)$ is untrue for all the $j \in 1 \ldots s$, then $M(q)$ only consists of $x = 0$. Both of these consequences have been formulated in the claim. □

15.6 Proofs of Chapter 5

Proof of (5.3):

(i) If $x \in L(p)$ then there is some $n \in \mathbb{N}$ such that $p^n x = 0$. In particular, as R is commutative, we find that $(ap)^n x = a^n(p^n x) = a^n\, 0 = 0$ such that $x \in L(ap)$, as well. Hence $L(p) \subseteq L(ap)$.

(ii) Clearly $0 \in L(p)$ since $p\,0 = 0$. Consider x, $y \in L(p)$ that is $p^m x = 0$ and $p^n y = 0$ for some m, $n \in \mathbb{N}$. If $a \in R$ then $p^m(ax) = a(p^m x) = a\,0 = 0$ such that $ax \in L(p)$ again. Now let $u := \max\{\, m, n \,\}$ then we also get $x + y \in L(p)$ from

$$p^u(x+y) \;=\; p^{u-m}(p^m x) + p^{u-n}(p^n y) \;=\; p^{u-m}\,0 + p^{u-n}\,0 \;=\; 0$$

(iii) First suppose that p annihilates M: As any $x \in L$ also is in $x \in M = M(p)$ there is some $n \in \mathbb{N}$ such that $p^n x = 0$. In particular we have $x \in L(p)$ again, such that p annihilates L, as well. Now consider $x + L \in M/L$, as $x \in M = M(p)$ we again find $p^n x = 0$ for some $n \in \mathbb{N}$. But thereby $p^n(x + L) = p^n x + L = 0 + L = 0 \in M/L$. And that is $x + L \in (M/L)(p)$ again.

Conversely suppose p annihilates both L and M/L and consider any $x \in M$. Then there is some $u \in \mathbb{N}$ such that $p^u(x + L) = 0 + L$ but this is nothing but $p^u x \in L$. Again, as p annihilates L, this means there is some $v \in \mathbb{N}$, such that $p^v(p^u x) = 0$. Now let $n := u + v$, then $p^n x = p^v(p^u x) = 0$ such that $x \in M(p)$. And as this is true for any $x \in M$ we have shown, that p annihilates M, too.

(iv) Consider any $x \in L_1 + \cdots + L_r$, that is x is of the form $x = x_1 + \cdots + x_r$ for some $x_i \in L_i$. As p annihilates all the L_i, there are some $n(i) \in \mathbb{N}$ such that $p^{n(i)} x_i = 0$. Now let $n := \max\{\, n(1), \ldots, n(r) \,\}$ then we easily compute

$$p^n x \;=\; \sum_{i=1}^{r} p^{n-n(i)} p^{n(i)} x_i \;=\; \sum_{i=1}^{r} p^{n-n(i)}\, 0 \;=\; 0$$

In particular we have $x \in (L_1 + \cdots + L_r)(p)$ and as x has been arbitrary this means, that p annihilates $L_1 + \cdots + L_r$ again.

(v) If $x \in M(p)$ then there is some $n \in \mathbb{N}$ such that $p^n x = 0$. In particular $0 = \varphi(p^n x) = p^n \varphi(x)$ such that $\varphi(x) \in N(p)$. And if $x \in \varphi^{-1}(N(p))$ that is $\varphi(x) \in N(p)$ there is some $n \in \mathbb{N}$ such that $0 = p^n \varphi(x) = \varphi(p^n x)$. If now φ is injective, then this implies $p^n x = 0$ such that $x \in M(p)$.

□

Proof of (5.6):

(i) Consider any $x \in R$ with $x \neq 0$. Then $\operatorname{ann}(x) = \{\, a \in R \mid ax = 0 \,\}$. But as $x \neq 0$ and R is an integral domain $ax = 0$ implies $a = 0$. Hence we get $\operatorname{ann}(x) = 0$. That is any annihilator ideal of R is 0.

Conversely: As $M \neq 0$ there there is some $x \in M \subseteq R$ with $x \neq 0$. And as we have seen, we get $\operatorname{ann}(x) = 0$ for this x, such that $0 \in \operatorname{Anns}(M)$. And as R is an integral domain $0 = \operatorname{ann}(x)$ is prime, such that $0 \in \operatorname{Sann}(M)$.

(ii) As $\operatorname{tor}(M) = 0$ we have $\operatorname{ann}(x) = R$ for $x = 0$ and $\operatorname{ann}(x) = 0$ for $x \neq 0$. By definition $\operatorname{ann}(0) = R$ never is a prime ideal and $\operatorname{ann}(x) = 0$ is a prime ideal if and only if R is an integral domain. If $M = 0$, then R is the only annihilator ideal of M and hence $\operatorname{Sann}(M) = \emptyset$. If $M \neq 0$, then $0 \in \operatorname{Sann}(M)$ if and only if R is an integral domain. Hence the two cases.

(iii) Let us first note, that $\operatorname{ann}(M)$ is a maximal ideal of R, as we have proved in (3.24.(i)) already. Also by the definition of $\operatorname{ann}(M)$ it is clear, that

$$\operatorname{ann}(M) \;=\; \bigcap_{z \in M} \operatorname{ann}(z)$$

In particular, if $x \in M$ with $x \neq 0$ then $\operatorname{ann}(x) \neq R$ [as $1 \notin \operatorname{ann}(x)$] but we also get $\operatorname{ann}(M) \subseteq \operatorname{ann}(x) \neq R$, so by maximality of $\operatorname{ann}(M)$ we get $\operatorname{ann}(x) = \operatorname{ann}(M)$. As $x \neq 0$ has been arbitrary this proves $\operatorname{Sann}(M) \subseteq \operatorname{Anns}(M) \subseteq \{\, \operatorname{ann}(M) \,\}$. But also, as $M \neq 0$, there is some $x \in M$ with $x \neq 0$. For this x we have just seen $\operatorname{ann}(x) = \operatorname{ann}(M)$. And as $\operatorname{ann}(M)$ is maximal, it also is prime. Therefore we have $\operatorname{ann}(M) \in \operatorname{Sann}(M)$, too.

(iv) Let us consider any proper ideal $\mathfrak{a} \neq R$ of R first: In this case $\operatorname{ann}(1+\mathfrak{a}) = \{\, a \in R \mid a + \mathfrak{a} = 0 + \mathfrak{a} \,\}$ such that $\operatorname{ann}(1+\mathfrak{a}) = \{\, a \in R \mid a \in \mathfrak{a} \,\} = \mathfrak{a}$. And as $\mathfrak{a}$ is proper we have $1 + \mathfrak{a} \neq 0$ such that we conclude $\mathfrak{a} \in \operatorname{Anns}_R(R/\mathfrak{a})$.

Now we turn to prime ideals $\mathfrak{p}$ of R only. Then conversely, if $\mathfrak{b} \in \operatorname{Anns}_R(R/\mathfrak{p})$, say $\mathfrak{b} = \operatorname{ann}(b+\mathfrak{p})$ for some $b \in R$ with $b + \mathfrak{p} \neq 0 + \mathfrak{p}$. This of course is $b \notin \mathfrak{p}$. Evaluation the annihilator we find $\mathfrak{b} = \operatorname{ann}(b+\mathfrak{p}) = \{\, a \in R \mid ab + \mathfrak{p} = 0 + \mathfrak{p} \,\}$. But $ab + \mathfrak{p} = 0 + \mathfrak{p}$ is equivalent to $ab \in \mathfrak{p}$ and as $\mathfrak{p}$ is prime and $b \notin \mathfrak{p}$ this again is equivalent to $a \in \mathfrak{p}$. Altogether this means $\mathfrak{b} = \{\, a \in R \mid a \in \mathfrak{p} \,\} = \mathfrak{p}$ such that $\mathfrak{p}$ also is the only element of $\operatorname{Anns}_R(R/\mathfrak{p})$.

(v) Of course $(R/\mathfrak{a})_\mathfrak{p} = 0$ means $(b+\mathfrak{a})/v = (0+\mathfrak{a})/1$ for any $b \in R$ and any $v \notin \mathfrak{p}$. And by construction of the localization, this is $u(b+\mathfrak{a}) = 0 + \mathfrak{a}$ for some $u \notin \mathfrak{p}$. This again is $ub \in \mathfrak{a}$, altogether

$$\left(R \Big/ \mathfrak{a}\right)_\mathfrak{p} = 0 \quad\Longleftrightarrow\quad \forall\, b \in R \;\; \exists\, u \notin \mathfrak{p} \;:\; ub \in \mathfrak{a}$$

Let us first regard the case $\mathfrak{a} \subseteq \mathfrak{p}$ and take $b = 1$. Then $u \in \mathfrak{a} \subseteq \mathfrak{p}$ and $u \notin \mathfrak{p}$ is a contradiction. Therefore $(R/\mathfrak{a})_\mathfrak{p} \neq 0$ and hence $\mathfrak{p} \in \operatorname{Supp}_R(R/\mathfrak{a})$. Conversely, if $\mathfrak{a} \subseteq \mathfrak{p}$ is false, there is some $u \in \mathfrak{a}$ such that $u \notin \mathfrak{p}$. Then for any $b \in R$ we have $ub \in \mathfrak{a}$ (as $\mathfrak{a}$ is an ideal) and hence $(R/\mathfrak{a})_\mathfrak{p} = 0$. This again is $\mathfrak{p} \notin \operatorname{Supp}_R(R/\mathfrak{a})$.

Proof of (5.7):

(i) By definition $\operatorname{ann}(x) = \{\, a \in R \mid ax = 0 \,\}$. Now, as ι is injective we have $a\iota(x) = \iota(ax) = 0$ if and only if $ax = 0$. That is the following sets are identical

$$\operatorname{ann}(\iota(x)) \;=\; \{\, a \in R \mid a\iota(x) = 0 \,\} \;=\; \{\, a \in R \mid ax = 0 \,\} \;=\; \operatorname{ann}(x)$$

Therefore, if $\mathfrak{a} \in \operatorname{Anns}_R(M)$, then $\mathfrak{a} = \operatorname{ann}(x)$ for some $x \neq 0$. But as $\iota(x) \neq 0$ again, as ι is injective, this means $\mathfrak{a} = \operatorname{ann}(x) = \operatorname{ann}(\iota(x)) \in \operatorname{Anns}_R(N)$. Thus we have the inclusion $\operatorname{Anns}_R(M) \subseteq \operatorname{Anns}_R(N)$. In particular this reasoning is true if $\mathfrak{a}$ is a prime ideal of R, such that the inclusion $\operatorname{Sann}_R(M) \subseteq \operatorname{Sann}_R(N)$ is true, as well.

Consider any $\mathfrak{p} \in \mathrm{Supp}_R(M)$, that is $M_\mathfrak{p} \neq 0$. Then ι induces another monomorphism $\iota_\mathfrak{p} : M_\mathfrak{p} \hookrightarrow N_\mathfrak{p}$ according to (3.125.(ii)). In particular $N_\mathfrak{p}$ cannot be zero (this would deny $\iota_\mathfrak{p}$ to be injective) such that $\mathfrak{p} \in \mathrm{Supp}_R(N)$ again.

(ii) If $\mathfrak{a} = \mathrm{ann}(x)$ for some $x \in M$ then we regard the homomorphism of R-modules $R \to Rx : a \mapsto ax$. By construction this is surjective and $\mathfrak{a}$ is its kernel. Hence we have the isomorphism

$$R\Big/_{\mathfrak{a}} \xrightarrow{\sim} Rx \ : \ b + \mathfrak{a} \mapsto bx$$

If conversely $\Phi : R/\mathfrak{p} \xrightarrow{\sim} Rx$ is an isomorphism of R-modules, then by (i) the set of annihilators of $R/\mathfrak{p}$ and Rx are identical. But by (v) we hence find

$$\mathrm{Anns}_R(Rx) \ = \ \mathrm{Anns}_R\left(R\Big/_{\mathfrak{p}}\right) \ = \ \{\,\mathfrak{p}\,\}$$

If we have $x = 0$, then $Rx = 0$ so the isomorphy $Rx \cong_\mathrm{m} R/\mathfrak{p}$ would mean $\mathfrak{p} = R$, which contradicts R being prime. This means $x \neq 0$ and hence $\mathrm{ann}(x) \in \mathrm{Anns}_R(Rx) = \{\,\mathfrak{p}\,\}$ such that $\mathrm{ann}(x) = \mathfrak{p}$.

(iii) Abbreviate $\mathrm{Supp}(M) := \{\,\mathfrak{p} \in \mathrm{Spec}(R) \mid \exists\, x \in M : \mathrm{ann}(x) \subseteq \mathfrak{p}\,\}$. In the first step we will prove that $\mathrm{Supp}(M) \subseteq \mathbb{V}(\mathrm{ann}(M))$: As $\{\,x\,\} \subseteq M$ it is clear that $\mathrm{ann}(M) \subseteq \mathrm{ann}(x)$ and by assumption any $\mathfrak{p} \in \mathrm{Supp}(M)$ satisfies $\mathrm{ann}(M) \subseteq \mathrm{ann}(x) \subseteq \mathfrak{p}$ for some $x \in M$. Therefore (by choosing this $x \in M$) $\mathrm{ann}(M) \subseteq \mathfrak{p}$ which is $\mathfrak{p} \in \mathbb{V}(\mathrm{ann}(M))$.

In the next step we will prove $\mathbb{V}(\mathrm{ann}(M)) \subseteq \{\,\mathfrak{p} \in \mathrm{Spec}(R) \mid M_\mathfrak{p} \neq 0\,\}$. So what does $M_\mathfrak{p} = 0$ mean? By definition this is $x/v = 0/1$ for any $x \in M$ and any $v \notin \mathfrak{p}$. And this again is: For any $x \in M$ there is some $u \notin \mathfrak{p}$ such that $ux = 0$. So if we start with some $\mathfrak{p} \in \mathbb{V}(\mathrm{ann}(M))$, then we have $\mathrm{ann}(M) \subseteq \mathfrak{p}$. In particular $u \notin \mathfrak{p}$ implies $u \notin \mathrm{ann}(M)$. And by definition of $\mathrm{ann}(M)$ this is $ux \neq 0$ for some $x \in M$ - just what we needed, for $M_\mathfrak{p} \neq 0$.

In the last step we will prove $\{\,\mathfrak{p} \in \mathrm{Spec}(R) \mid M_\mathfrak{p} \neq 0\,\} \subseteq \mathrm{Supp}(M)$. That is we start with some prime ideal $\mathfrak{p}$ such that $M_\mathfrak{p} \neq 0$ and need to prove that there is some $x \in M$ such that $\mathrm{ann}(x) \subseteq \mathfrak{p}$. That is we have to show that $u \in \mathrm{ann}(x)$ - which is $ux = 0$ - implies $u \in \mathfrak{p}$. As we have argued above $M_\mathfrak{p} = 0$ means $\forall\, x \in M\ \exists\, u \notin \mathfrak{p}$ such that $ux = 0$. The negation thereof is $\exists\, x \in M\ \forall\, u \notin \mathfrak{p}$ we get $ux \neq 0$. Yet $u \notin \mathfrak{p} \implies ux \neq 0$ is equivalent to $ux = 0 \implies u \in \mathfrak{p}$. Thus there is some $x \in M$ such that $u \in \mathrm{ann}(x)$ implies $u \in \mathfrak{p}$ which is just what we needed: $\mathrm{ann}(x) \subseteq \mathfrak{p}$.

(iv) By definition $\mathrm{ann}(x) = \{\,a \in R \mid ax = 0\,\}$ and if we rewrite the quantifier $\exists\, x \in M : x \neq 0$ as a union over all $x \in M$ with $x \neq 0$ the identity of these sets is readily apparent

$$\mathrm{zd}(M) \ = \ \bigcup_{x \neq 0} \{\,a \in R \mid ax = 0\,\} \ = \ \bigcup_{x \neq 0} \mathrm{ann}(x) \ = \ \bigcup \mathrm{Anns}(M)$$

(v) Let $\mathfrak{a} = \mathrm{ann}(x)$ for some $x \neq 0$ and consider $a, b \in R$ such that $ab \in \mathfrak{a}$ and $b \notin \mathfrak{a}$. Then we need to prove $a \in \mathfrak{a}$. By assumption we have $abx = 0$ and $bx \neq 0$, that is $a \in \mathrm{ann}(bx) \in \mathrm{Anns}(M)$. But clearly $\mathfrak{a} = \mathrm{ann}(x) \subseteq \mathrm{ann}(bx)$, as R is commutative. By maximality of $\mathfrak{a}$ this implies $\mathfrak{a} = \mathrm{ann}(bx)$ and hence $a \in \mathfrak{a}$, which had to be proved.

□

Proof of (5.8):

(i) If $\mathfrak{p} = \mathrm{ann}(x) \in \mathrm{Sann}(P)$, then as $0 \neq x \in P \subseteq M$ we already find $\mathfrak{p} = \mathrm{ann}(x) \in \mathrm{Sann}(M)$. Thereby we already have the inclusion

$$\mathrm{Sann}(P) \quad \subseteq \quad \mathrm{Sann}(M)$$

Now consider any $x \in M$ and distinguish two cases: If $Rx \cap P = 0$ (as $ax \in Rx$ is generally true) then $ax \in P$ is equivalent to $ax \in Rx \cap P = 0$ and hence to $ax = 0$. Therefore

$$\begin{aligned} \mathrm{ann}(x+P) &= \{\, a \in R \mid a(x+P) = 0 \in M/P \,\} \\ &= \{\, a \in R \mid ax \in P \,\} \\ &= \{\, a \in R \mid ax = 0 \,\} \;=\; \mathrm{ann}(x) \end{aligned}$$

In particular $\mathrm{ann}(x) = \mathrm{ann}(x+P) \in \mathrm{Sann}(M/P)$. In the complementary case $Rx \cap P \neq 0$ there is some $y = bx \in P$ such that $y \neq 0$. In particular $b \notin \mathrm{ann}(x) = \mathfrak{p}$. Then (3.24.(ii)) tells us that $\mathrm{Anns}(Ry) = \{\, \mathfrak{p} \,\}$ and in particular $\mathrm{ann}(y) = \mathfrak{p} = \mathrm{ann}(x)$. That is $\mathrm{ann}(x) = \mathrm{ann}(y) \in \mathrm{Sann}(P)$. Together we have found

$$\mathrm{Sann}(M) \;\subseteq\; \mathrm{Sann}(P) \cup \mathrm{Sann}\left(M \Big/ P\right)$$

(i) If $0 \to L \to M \to N \to 0$ is an exact chain of R-modules, let us denote the respective homomorphisms by $\varphi : L \hookrightarrow M$ and $\psi : M \twoheadrightarrow N$. Then $L \xrightarrow{\sim} \mathrm{im}(\varphi) = \mathrm{kn}(\psi)$ due to exactness, such that

$$\mathrm{Sann}(L) \;=\; \mathrm{Sann}(\mathrm{kn}(\psi)) \quad \subseteq \quad \mathrm{Sann}(M)$$

as $P := \mathrm{kn}(\psi) \;\leq_{\mathfrak{m}}\; M$ is a sub-module of M and we have (i) above. Also the first isomorphism theorem implies $M/\mathrm{kn}(\psi) \xrightarrow{\sim} \mathrm{im}(\psi) = N$ such that (i) above also implies

$$\mathrm{Sann}(M) \;\subseteq\; \mathrm{Sann}(\mathrm{kn}(\psi)) \cup \mathrm{Sann}\left(M \Big/ \mathrm{kn}(\psi)\right) \;=\; \mathrm{Sann}(L) \cup \mathrm{Sann}(N)$$

(ii) As any $P_i \;\leq_{\mathfrak{m}}\; M$ is a sub-module, we have $\mathrm{Sann}(P_i) \subseteq \mathrm{Sann}(M)$ by (vi). Therefore $\bigcup_i \mathrm{Sann}(P_i)$ is contained in $\mathrm{Sann}(M)$. Conversely consider any $\mathfrak{p} = \mathrm{ann}(x) \in \mathrm{Sann}(M)$. As $x \in M = \bigcup_i P_i$ there is some $i \in I$ such that $x \in P_i$ and thereby $\mathfrak{p} = \mathrm{ann}(x) \in \mathrm{Sann}(P_i)$. That is $\mathrm{Sann}(M)$ also is contained in $\bigcup_i \mathrm{Sann}(P_i)$.

(iv) If $\#I = 1$ then there is nothing to prove. If $\#I = 2$, say $I = \{\, 1, 2 \,\}$ we abbreviate $M := M_1 \oplus M_2$. As $M_1 \subseteq M$ (canonically under $x_1 \mapsto (x_1, 0)$ we have $\mathrm{Sann}(M_1) \subseteq \mathrm{Sann}(M)$ according to (iv). Likewise $\mathrm{Sann}(M_2) \subseteq \mathrm{Sann}(M)$. And clearly $M/M_1 \xrightarrow{\sim} M_2 : (x_1, x_2) + M_1 \mapsto x_2$ is an isomorphism and hence we may apply (iv) to find

$$\begin{aligned} \mathrm{Sann}(M) &\subseteq \mathrm{Sann}(M_1) \cup \mathrm{Sann}\left(M \Big/ M_1\right) \\ &= \mathrm{Sann}(M_1) \cup \mathrm{Sann}(M_2) \end{aligned}$$

But as we also have $\mathrm{Sann}(M_1) \cup \mathrm{Sann}(M_2) \subseteq \mathrm{Sann}(M)$ we have the equality of these sets. Thus we have proved the claim for $\#I = 2$. Now suppose I is a finite set, then we may use induction on $n := \#I$. The cases $n = 1$ and $n = 2$ have already been dealt with. For the induction step we consider $I = 1 \ldots (n+1)$ and let $M := Q \oplus M_{n+1}$ where $Q := M_1 \oplus \cdots \oplus M_n$. Then we may use

the case $n = 2$ on M and the induction hypothesis on Q to find

$$\begin{aligned}\mathrm{Sann}(M) &= \mathrm{Sann}(Q) \cup \mathrm{Sann}(M_{n+1}) \\ &= \bigcup_{i=1}^{n} \mathrm{Sann}(M_i) \cup \mathrm{Sann}(M_{n+1}) = \bigcup_{i=1}^{n+1} \mathrm{Sann}(M_i)\end{aligned}$$

For an infinite index set I we finally let $\Omega := \{ A \subseteq I \mid A \neq \emptyset, \#A < \infty \}$. Then for some non-empty finite subset $A \in \Omega$ of I we let

$$\begin{aligned}M &:= \bigoplus_{i \in A} M_i \\ M_A &:= \bigoplus_{i \in A} M_i \quad \leq_{\mathfrak{m}} \quad M\end{aligned}$$

By construction any $x \in M$ is contained in some $x \in M_A$ for some $A \in \Omega$. That is $M = \bigcup_A M_A$ where the union runs over $A \in \Omega$. Now by (ii) the annihilator spectrum if the union of the annihilator spectra of M_A and as A is finite these are given to be

$$\mathrm{Sann}(M) = \bigcup_{A \in \Omega} \mathrm{Sann}(M_A) = \bigcup_{A \in \Omega} \bigcup_{i \in A} \mathrm{Sann}(M_i) = \bigcup_{i \in I} \mathrm{Sann}(M_i)$$

(iii) By assumption the following map is injective: If $(x + P_i) = 0 = (0 + P_i)$ then we have $x \in P_i$ for any $i \in I$. But as $x \in \bigcup_i P_i = 0$ is $x = 0$ we find the injectivity, of

$$M \hookrightarrow \bigoplus_{i \in I} M \big/ P_i \; : \; x \mapsto (x + P_i)$$

That is we can consider M as a sub-module of the direct sum of the M/P_i and by (i) and (iv) this implies our claim

$$\mathrm{Sann}(M) \subseteq \mathrm{Sann}\left(\bigoplus_{i \in I} M \big/ P_i \right) = \bigcup_{i \in I} \mathrm{Sann}\left(M \big/ P_i \right)$$

(v) As $\mathfrak{p} \in \mathrm{Spec}(R)$ already is a prime ideal, we have $\mathfrak{p} \in \mathrm{Sann}(M)$ if and only if $\mathfrak{p} \in \mathrm{Anns}(M)$. But as $\mathfrak{p} \neq R$ is proper this is equivalent to the existence of ι according to (3.22.(ii)).

(vi) If $M = 0$ then there is no $x \in M$ with $x \neq 0$. Therefore $\mathrm{Sann}(M) = \emptyset$ by construction. Conversely if $M \neq 0$ then there is some $x \in M$ with $x \neq 0$. That is $1 \notin \mathrm{ann}(x)$ and thereby $\mathrm{ann}(x) \neq R$. In particular $\mathcal{A} := \mathrm{Anns}(M) \neq \emptyset$. As R is noetherian and $\mathcal{A}$ is non-empty we get $\mathcal{A}^* \neq \emptyset$ as well. And as the maximal elements of $\mathcal{A}$ are prime ideals by (3.24.(iii)) we have $\emptyset \neq \mathcal{A}^* \subseteq \mathrm{Spec}(R) \cap \mathrm{Anns}(M) = \mathrm{Sann}(M)$.

(vii) First of all, we regard the case $M = 0$: Here $\mathrm{Sann}(M) = \emptyset$ and hence the grand union of $\mathrm{Sann}(M)$ is empty, too. But also $\mathrm{zd}(M) = \emptyset$, as there is no $x \neq 0$ to begin with. That is in case $M = 0$ we have the equality and may assume $M \neq 0$ from now on:

If $\mathfrak{p} \in \mathrm{Sass}(M)$ is an associated prime of M, then $\mathfrak{p} = \mathrm{ann}(x)$ for some $x \neq 0$. That is any $a \in \mathfrak{p}$ satisfies $ax = 0$ and as $x \neq 0$ this means $a \in \mathrm{zd}(M)$. Hence $\mathfrak{p} \subseteq \mathrm{zd}(M)$ which is "$\subseteq$" above.

For the converse inclusion we start with some $a \in \mathrm{zd}(M)$, that is there is some $x \neq 0$ such that $ax = 0$. In particular $Rx \neq 0$ such that by (vi) there is some $\mathfrak{p} \in \mathrm{Sann}(Rx) \subseteq \mathrm{Sann}(M)$. Say $\mathfrak{p}$ is $\mathfrak{p} = \mathrm{ann}(bx)$ for some $bx \neq 0$. Then $a(bx) = b(ax) = b \cdot 0 = 0$ such that $a \in \mathfrak{p} \in \mathrm{Sann}(M)$. That is a is contained in the grand union of $\mathrm{Sann}(M)$.

(viii) Let $\mathcal{Z} := \{\, Z \leq_{\mathfrak{m}} M \mid \mathrm{Sann}(Z) \subseteq \mathcal{S} \,\}$ be the set of sub-modules of M whose annihilator spectrum is contained in $\mathcal{S}$. From (vi) we know $\mathrm{Sann}(0) = \emptyset \subseteq \mathcal{S}$ such that $0 \in \mathcal{Z}$ which tells us that $\mathcal{Z}$ is non-empty. And if $(Z_i) \subseteq \mathcal{Z}$ is a chain then $Z := \bigcup_i Z_i$ is a sub-module by (3.13). Also we have

$$\mathrm{Sann}(Z) \;=\; \bigcup_{i \in I} \mathrm{Sann}(Z_i) \;\subseteq\; \mathcal{S}$$

according to (ii). This means $Z \in \mathcal{Z}$ again and thereby any chain in $\mathcal{Z}$ has an upper bound such that we may apply the lemma of Zorn (0.29) to find a maximal element $P \in \mathcal{Z}^*$. As $P \in \mathcal{Z}$ we have $\mathrm{Sann}(P) \subseteq \mathcal{S}$. Let us now argue, that

$$\mathrm{Sann}\left(M \Big/ P\right) \cap \mathcal{S} \;=\; \emptyset$$

Consider any $\mathfrak{p} \in \mathrm{Sann}(M/P)$ then we have a monomorphism of the form $\iota : R/\mathfrak{p} \hookrightarrow M/P$ by (v). Let $Q/P := \mathrm{im}(\iota)$ be the image of this, that is $Q \leq_{\mathfrak{m}} M$ with $P \subseteq Q$. Then $\iota : R/\mathfrak{p} \xrightarrow{\sim} Q/P$ is an isomorphism. In particular $\mathrm{Sann}(Q/P) = \mathrm{Sann}(R/\mathfrak{p}) = \{\, \mathfrak{p} \,\}$ and by (i) we hence get

$$\mathrm{Sann}(Q) \;\subseteq\; \mathrm{Sann}(P) \cup \mathrm{Sann}\left(Q \Big/ P\right) \;=\; \mathrm{Sann}(P) \cup \{\, \mathfrak{p} \,\}$$

If we had $\mathfrak{p} \in \mathcal{S}$ as well, then this would mean $\mathrm{Sann}(Q) \subseteq \mathcal{S}$. But as P is maximal with this property and $P \subseteq Q$ this would yield $P = Q$ which contradicts $Q/P \cong_{\mathfrak{m}} R/\mathfrak{p} \neq 0$. Thus $\mathcal{S}$ and $\mathrm{Sann}(M/P)$ are disjoint. But from this we will find

$$\mathrm{Sann}(P) \;=\; \mathcal{S}$$

We already have $\mathrm{Sann}(P) \subseteq \mathcal{S}$, so let us suppose there was some $\mathfrak{p} \in \mathcal{S} \setminus \mathrm{Sann}(P)$. As $\mathfrak{p} \in \mathcal{S} \subseteq \mathrm{Sann}(M) \subseteq \mathrm{Sann}(P) \cup \mathrm{Sann}(M/P)$ but $\mathfrak{p} \notin \mathrm{Sann}(P)$ we necessarily have $\mathfrak{p} \in \mathrm{Sann}(M/P)$. But this cannot be, as $\mathcal{S}$ and $\mathrm{Sann}(M/P)$ are disjoint, which only leaves $\mathrm{Sann}(P) = \mathcal{S}$. And thereby

$$\mathrm{Sann}(M) \setminus \mathcal{S} \;=\; \mathrm{Sann}(M) \setminus \mathrm{Sann}(P) \;\subseteq\; \mathrm{Sann}\left(M \Big/ P\right)$$

□

Proof of (5.12):

(i) Recall the canonical map $\kappa : R \to U^{-1}R : a \mapsto a/1$. By definition $U^{-1}\mathrm{ann}(x)$ is the ideal of $U^{-1}R$ generated by $\kappa(\mathrm{ann}(x))$

$$\begin{aligned} U^{-1}\mathrm{ann}(x) &= \langle \left\{ \frac{a}{1} \mid a \in \mathrm{ann}(x) \right\} \rangle_{\mathfrak{i}} \\ &= \langle \left\{ \frac{a}{1} \mid a \in R,\, ax = 0 \right\} \rangle_{\mathfrak{i}} \end{aligned}$$

Likewise $\mathrm{ann}(x/1) \trianglelefteq_{\mathfrak{i}} U^{-1}R$ is the set of all $a/u \in U^{-1}R$ such that $ax/u = a/u\,x/1 = 0/1$. The

latter is equivalent to: $wax = wu0 = 0$ for some $w \in U$. That is

$$\operatorname{ann}\left(\frac{x}{1}\right) \;=\; \left\{ \frac{a}{u} \in U^{-1}R \mid \exists\, w \in U \,:\, wax = 0 \right\}$$

We will now prove that (under the assumption $\mathfrak{p} = \operatorname{ann}(x)$ is a prime ideal, with $\mathfrak{p} \cap U = \emptyset$) these sets are equal: For $U^{-1}\operatorname{ann}(x) \subseteq \operatorname{ann}(x/1)$ we consider some $a \in R$ with $ax = 0$. Then clearly $a/1 \in \operatorname{ann}(x/1)$, as we have $wax = 0$ for $w = 1 \in U$. And as $\operatorname{ann}(x/1)$ is an ideal, it therefore contains $U^{-1}\operatorname{ann}(x)$.

Conversely we take a look some a/u such that $wax = 0$ for some $w \in U$. That means $wa \in \operatorname{ann}(x) = \mathfrak{p}$. As $w \in U$ we have $w \notin \mathfrak{p}$ and as $\mathfrak{p}$ is a prime ideal, this implies $a \in \mathfrak{p} = \operatorname{ann}(x)$. That is $ax = 0$ and hence $a/1 \in U^{-1}\operatorname{ann}(x)$. But as this is an ideal, we also have $a/u = (1/u) \cdot (a/1) \in U^{-1}\operatorname{ann}(x)$.

(ii) We have already seen in (2.129) that $\mathfrak{p} \mapsto U^{-1}\mathfrak{p}$ is a bijective map from $\mathcal{S} := \{\, \mathfrak{p} \in \operatorname{Spec}(R) \mid \mathfrak{p} \cap U = \emptyset \,\}$ to $\operatorname{Spec}(U^{-1}R)$. So if $\mathfrak{p} = \operatorname{ann}(x) \in \operatorname{Sann}(M)$ with $\mathfrak{p} \cap U = \emptyset$, then by (i) we see that $U^{-1}\mathfrak{p} = \operatorname{ann}(x/1) \in \operatorname{Sann}(U^{-1}M)$. Hence the map is well-defined and its injectivity is inherited from the bijectivity on the spectrum.

(iii) By assumption $\mathfrak{p} = \langle a_1, \ldots, a_n \rangle_{\mathfrak{i}} \trianglelefteq_{\mathfrak{i}} R$ is finitely generated and $U^{-1}\mathfrak{p} = \operatorname{ann}(x/u)$ is the annihilator of some element $x/u \in U^{-1}M$. As in (i) this ideal can be explicitly written, as

$$\operatorname{ann}\left(\frac{x}{u}\right) \;=\; \left\{ \frac{b}{v} \in U^{-1}R \mid \exists\, w \in U \,:\, wbx = 0 \right\}$$

For any $k \in 1 \ldots n$ we have $a_k \in \mathfrak{p}$ and therefore $a_k/1 \in U^{-1}\mathfrak{p} = \operatorname{ann}(x/u)$ which means $(a/1)\,(x/u) = 0/1$ and this is $w_k a_k x = 0$ for some $w_k \in U$. Now let $w := w_1 \ldots w_n \in U$ then clearly $a_k(wx) = wa_k x = 0$ for any $k \in 1 \ldots n$. This means $a_k \in \operatorname{ann}(wx)$ and as the a_k generate $\mathfrak{p}$ we even get the inclusion

$$\mathfrak{p} \;\subseteq\; \operatorname{ann}(wx)$$

Conversely, if $b \in \operatorname{ann}(wx)$ then $wbx = bwx = 0$ which means $b/1 \in \operatorname{ann}(x/u) = U^{-1}\mathfrak{p}$. But this implies $b \in U^{-1}\mathfrak{p} \cap R = \mathfrak{p}$ such that we also have $\operatorname{ann}(wx) \subseteq \mathfrak{p}$. But together this is $\mathfrak{p} = \operatorname{ann}(wx) \in \operatorname{Sann}(M)$ as claimed.

(ii) Now consider any $\mathfrak{q} \in \operatorname{Sann}(U^{-1}M) \subseteq \operatorname{Spec}(U^{-1}R)$. As the map is bijective on the spectrum, there is some $\mathfrak{p} \in \operatorname{Spec}(R)$ such that $\mathfrak{p} \cap U = \emptyset$ and $\mathfrak{q} = U^{-1}\mathfrak{p}$. If R is noetherian, then $\mathfrak{p}$ is finitely generated and hence we may apply (iii) to get $\mathfrak{p} \in \operatorname{Sann}(M)$. That is $\mathfrak{p} \mapsto U^{-1}\mathfrak{p} = \mathfrak{q}$ and hence this map also is surjective.

(iv) By (5.8.(vii)) there is a sub-module $Q \leq_{\mathfrak{m}} M$ that satisfies $\operatorname{Sann}(Q) = \operatorname{Sann}(M) \setminus \mathcal{S}$ and $\operatorname{Sann}(Q) \cap \operatorname{Sann}(M/Q) = \emptyset$. By definition of $\mathcal{S}$ this means, that for any $\mathfrak{p} \in \operatorname{Sann}(M)$ we have

$$\mathfrak{p} \in \operatorname{Sann}(Q) \iff \mathfrak{p} \notin \mathcal{S} \iff \mathfrak{p} \cap U \neq \emptyset$$

And as by (5.8.(i)) any $\mathfrak{p} \in \operatorname{Sann}(M)$ is contained in either $\operatorname{Sann}(Q)$ or in $\operatorname{Sann}(M/Q)$ this means $\operatorname{Sann}(M/Q) = \mathcal{S}$. Now let us also denote $\kappa : M \to U^{-1}M : x \mapsto x/1$ and $P := \operatorname{kn}(\kappa)$. Then we

regard the following commutative diagram

$$\begin{array}{ccc} M & \xrightarrow{\varrho} & M/Q \\ \downarrow & & \downarrow \\ U^{-1}M & \underset{U^{-1}\varrho}{\longrightarrow} & U^{-1}(M/Q) \end{array}$$

where κ and $\overline{\kappa} : M/Q \to U^{-1}(M/Q) : x+Q \mapsto (x+Q)/1$ are the canonical homomorphisms downwards and $\varrho : M \to M/Q : x \mapsto x+Q$ is the canonical projection. By definition $U^{-1}\varrho : U^{-1}M \to U^{-1}(M/Q)$ is defined by $U^{-1}\varrho(x/u) := (x+Q)/u$. This diagram commutes, as

$$\overline{\kappa}\varrho(x) \;=\; \frac{x+Q}{1} \;=\; \big(U^{-1}\varrho\big)\kappa(x)$$

We first claim, that $U^{-1}\varrho$ is injective: That is we need to show that $\mathrm{kn}(U^{-1}\varrho) = 0$. Hereby (3.125.(ii)) tells us $\mathrm{kn}(U^{-1}\varrho) = U^{-1}\mathrm{kn}(\varrho) = U^{-1}Q$. And as R is noetherian we know by (ii) that $\mathrm{Sann}(U^{-1}Q)$ is bijective to $\{\,\mathfrak{p} \in \mathrm{Sann}(Q) \mid \mathfrak{p} \cap U = \emptyset\,\} = \emptyset$. But by construction of $\mathcal{S}$ and Q the latter set is void and hence $\mathrm{Sann}(U^{-1}Q) = \emptyset$ is empty, as well. But by (5.8.(vi)) this means $\mathrm{kn}(U^{-1}\varrho) = U^{-1}Q = 0$, such that $U^{-1}\varrho$ is injective.

Next we claim, that $\overline{\kappa}$ is injective, as well: To do this let $K/Q := \mathrm{kn}(\overline{\kappa}) \;\leq_{\mathfrak{m}}\; M/Q$, then $\mathrm{Sann}(K/Q) \subseteq \mathrm{Sann}(M/Q) = \mathcal{S}$. Now consider any $\mathfrak{p} \in \mathrm{Sann}(K/Q)$, that is $\mathfrak{p} = \mathrm{ann}(x+Q)$ for some $x \in K \;\leq_{\mathfrak{m}}\; M$. As $x+Q \in \mathrm{kn}(\overline{\kappa})$ we have $(x+Q)/1 = 0/1 \in U^{-1}(M/Q)$ and this means $w(x+Q) = 0+Q$ for some $w \in U$. That is $w \in U$ annihilates $x+Q$ such that $w \in \mathrm{ann}(x+Q) \cap U = \mathfrak{p} \cap U$. But as $\mathfrak{p} \in \mathcal{S}$ we have $\mathfrak{p} \cap U = \emptyset$. This contradiction can only be solved, if there is no $\mathfrak{p} \in \mathrm{Sann}(K/Q)$ which means $\mathrm{Sann}(K/Q) = 0$. Using (5.8.(vi)) again this is $\mathrm{kn}(\overline{\kappa}) = K/Q = 0$, such that $\overline{\kappa}$ is injective.

Using both injectivities we find $Q = P$ (see below). And as Q has been *any* sub-module of M satisfying $\mathrm{Sann}(Q) = \mathrm{Sann}(M) \setminus \mathcal{S}$ and $\mathrm{Sann}(Q) \cap \mathrm{Sann}(M/Q) = \emptyset$ this proves the uniqueness of Q. Also P inherits these properties from Q.

$$Q \;=\; \mathrm{kn}(\varrho) \;=\; \mathrm{kn}(\overline{\kappa}\varrho) \;=\; \mathrm{kn}\Big(\big(U^{-1}\varrho\big)\kappa\Big) \;=\; \mathrm{kn}(\kappa) \;=\; P$$

□

Proof of (5.13):
Let $S := R_{\mathfrak{p}}$ abbreviate the localisation of R in $\mathfrak{p}$, then S is noetherian, too, according to (2.131). Also $M_{\mathfrak{p}} \neq 0$, as $\mathfrak{p} \in \mathrm{Supp}(M)$ such that $\mathrm{Sann}_S(M_{\mathfrak{p}}) \neq \emptyset$ is non-empty, by (5.8.(vi)). But (5.12.(ii)) tells us, that there is a one-to-one correspondence between the sets

$$\mathrm{Sann}_S\,(M_{\mathfrak{p}}) \;\longleftrightarrow\; \{\,\mathfrak{a} \in \mathrm{Sann}_R(M) \mid \mathfrak{a} \cap (R \setminus \mathfrak{p}) = \emptyset\,\}$$

As the left-hand set is non-empty, so is the right-hand set, that is there is some $\mathfrak{a} \in \mathrm{Sann}(M)$ such that $\mathfrak{a} \cap (R \setminus \mathfrak{p}) = \emptyset$. But the latter property translates into $\mathfrak{a} \subseteq \mathfrak{p}$.

Consider any $\mathfrak{a} = \mathrm{ann}(x) \in \mathrm{Sann}(M)$, that is $x \neq 0$ and $\mathfrak{a}$ is prime. In particular $\mathrm{ann}(x) \subseteq \mathfrak{a} \in \mathrm{Spec}(R)$,

such that $\mathfrak{a} \in \mathrm{Supp}(M)$, by construction of the support. From this we see the inclusion

$$\mathrm{Sann}(M) \quad \subseteq \quad \mathrm{Supp}(M)$$

It remains to prove that the minimal elements of these sets coincide. If $\mathfrak{p} \in \mathrm{Supp}(M)$ is minimal, then we choose some $\mathfrak{a} \in \mathrm{Sann}(M)$ such that $\mathfrak{a} \subseteq \mathfrak{p}$. As $\mathfrak{a} \in \mathrm{Supp}(M)$, too and $\mathfrak{p}$ is minimal in this set we find $\mathfrak{a} = \mathfrak{p}$, in particular $\mathfrak{p} \in \mathrm{Sann}(M)$ is an associated prime of M. And clearly it is minimal in $\mathrm{Sann}(M)$, as any $\mathrm{Sann}(M)$ is contained in $\mathrm{Supp}(M)$.
Conversely if $\mathfrak{a} \in \mathrm{Sann}(M)$ is minimal, then we already know $\mathfrak{a} \in \mathrm{Supp}(M)$, but have to show, that it also is minimal in this set. That is we consider some $\mathfrak{p} \in \mathrm{Supp}(M)$ such that $\mathfrak{p} \subseteq \mathfrak{a}$ and have to show $\mathfrak{a} = \mathfrak{p}$. Again choose some $\mathfrak{b} \in \mathrm{Sann}(M)$ such that $\mathfrak{b} \subseteq \mathfrak{p} \subseteq \mathfrak{a}$. As $\mathfrak{a}$ is minimal in $\mathrm{Sann}(M)$ and $\mathfrak{b} \in \mathrm{Sann}(M)$ we conclude $\mathfrak{a} = \mathfrak{b}$ and thereby $\mathfrak{a} = \mathfrak{p}$.
We have just shown, that the minimal elements of $\mathrm{Sann}(M)$ and $\mathrm{Supp}(M)$ coincide. For the grand intersection only minimal elements are relevant, though [if $\mathfrak{p} \in \mathrm{Sann}(M)$ is *not* minimal, then there is some $\mathfrak{p} \subseteq \mathfrak{q}$. And hence $\mathfrak{q}$ does not contribute to the intersection: $\mathfrak{p} \cap \mathfrak{q} = \mathfrak{p}$. The same is true for $\mathrm{Sann}(M)$ of course]. Thus we find

$$\bigcap \mathrm{Sann}(M) \;=\; \bigcap \big(\mathrm{Sann}(M)\big)_* \;=\; \bigcap \big(\mathrm{Supp}(M)\big)_* \;=\; \bigcap \mathrm{Supp}(M)$$

□

Proof of (5.11):

(i) By definition $M = M(p) = \{\, x \in M \mid \exists\, n \in \mathbb{N} : p^n x = 0 \,\}$. Yet Yet the condition in this set can be reformulated to $\exists\, n \in \mathbb{N} : p^n \in \mathrm{ann}(x)$ which in turn is $p \in \sqrt{\mathrm{ann}(x)}$. That is

$$M(p) \quad = \quad \left\{ x \in M \mid p \in \sqrt{\mathrm{ann}(x)} \right\}$$

Consider any $\mathfrak{p} \in \mathrm{Sann}(M)$, that is $\mathfrak{p} = \mathrm{ann}(x)$ for some $x \neq 0$, then $M = M(p)$ tells us $p \in \sqrt{\mathrm{ann}(x)}$ which is $pR \subseteq \sqrt{\mathrm{ann}(x)} = \mathrm{ann}(x)$ - the latter, as $\mathrm{ann}(x)$ is prime. Thus we have $p \in \mathrm{ann}(x)$. And as $x \neq 0$ we know $\mathrm{ann}(x) \neq R$ such that we have found

$$pR \quad \subseteq \quad \mathrm{ann}(x) \quad \neq \quad R$$

As R is a PID the non-zero prime ideal pR is maximal, according to (2.79.(i)) such that we find $\mathfrak{p} = \mathrm{ann}(x) = pR$ by the inclusion above. That is we have shown $\mathrm{Sann}(M) \subseteq \{\, pR \,\}$. On the other hand $M \neq 0$ is finitely generadet (by assumption) such that from (5.8.(vi)) we have $\mathrm{Sann}(M) \neq \emptyset$. But this leaves $\mathrm{Sann}(M) = \{\, pR \,\}$ only.

(ii) By (5.13) we know $\mathrm{Sann}(R/aR) \subseteq \mathrm{Supp}(R/aR)$ and by (5.6.(iv)) this is $\mathbb{V}(aR)$ such that we find

$$\begin{aligned} \mathrm{Sann}\left(R\big/_{aR}\right) \quad &\subseteq \quad \mathrm{Supp}\left(R\big/_{aR}\right) \\ &= \quad \mathbb{V}(aR) \;=\; \{\, pR \mid p \in R \text{ prime}, aR \subseteq pR \,\} \\ &= \quad \{\, pR \mid p \in R \text{ prime}, p \mid a \,\} \end{aligned}$$

For the converse inclusion we start with any prime $p \in R$ such that $p \mid a$, that is $pu = a$ for some

$u \in R$. As $a \neq 0$ so is $u \neq 0$. Now let $x := u + aR$. Suppose $x = 0$, then $u \in aR$, say $u = ab$ for some $b \in R$, then $u = ab = pub$ such that $1 = pb$ (as $u \neq 0$) which would be $p \in R^*$, in contradiction to p being prime. Thus $x \neq 0$ but $px = p(u + aR) = pu + aR = a + aR = 0 + aR$. That is $p \in \mathrm{ann}(x)$, i.e. $pR \subseteq \mathrm{ann}(x) \neq R$ (as in (i) above) such that we find $\mathrm{ann}(x) = pR$ again. In particular $\mathrm{ann}(x)$ is prime and hence $pR = \mathrm{ann}(x) \in \mathrm{Sann}(R/aR)$.

□

Proof of (5.14):

- First consider the case $M = 0$, then statement (2) is void and statement (1) is trivial for $n = 0$ and $M_0 = 0 = M$. So let us now deal with $M \neq 0$, as R is noetherian and M is finitely generated, M is noetherian, too, according to (3.111.(vi)). Hence we consider the set of all sub-modules of M that do satify properties (1) and (2) of the claim.

 First of all, this set is nonempty: As $M \neq 0$ there is some $\mathfrak{p} \in \mathrm{Sann}(M)$, due to (5.8.(vi)). Say $\mathfrak{p} = \mathrm{ann}(x)$ then $R/\mathfrak{p} \cong_{\mathsf{m}} Rx : a + \mathfrak{p} \mapsto ax$ is an isomorphism of R-modules and thereby Rx satisfies properties (1) and (2), as we may take $0 = M_0 \subset M_1 = Rx$ such that $M_1/M_0 \cong_{\mathsf{m}} Rx \cong_{\mathsf{m}} R/\mathfrak{p}$. Hence $Rx \leq_{\mathsf{m}} M$ is one of those sub-modules.

 As the set of sub-modules satisfying (1) and (2) is non-empty and M is noetherian, there is a maximal sub-module N satisfying (1) and (2). In particular there are some N_i and $\mathfrak{p}_i$ as in (1) and (2). We need to prove $N = M$, so suppose this was *not* the case: $N \subset M$. Then $M/N \neq 0$ and therefore $\mathrm{Sann}(M/N) \neq \emptyset$ again. Let $\mathfrak{p} = \mathrm{ann}(x + N)$ be an associated prime ideal of M/N, then we find the chain of sub-modules

$$0 = N_0 \subset N_1 \subset \ldots \subset N_n = N \subset N + Rx$$

 Also we have $R/\mathfrak{p} \cong_{\mathsf{m}} R(x + N) : a + \mathfrak{p} \mapsto ax + N$ as before. And as $(Rx + N)/N = R(x + N)$ we have found an extension of the chain $0 = N_0 \subset \ldots \subset N_n = N$ in contradiction to the maximality of N. But this only leaves $M/N = 0$, in other words $N = M$.

- We prove $\mathrm{Sann}(M) \subseteq \{\mathfrak{p}_1, \ldots, \mathfrak{p}_n\}$ by induction on n: In case $n = 0$, which is $M = 0$, we have $\mathrm{Sann}(M) = \emptyset$. Now consider $n = 1$ which is $0 = M_0 \subset M_1 = M$. Then we get

$$\mathrm{Sann}(M) = \mathrm{Sann}(M_1) = \mathrm{Sann}\left(M_1 \big/ M_0\right) = \mathrm{Sann}\left(R \big/ \mathfrak{p}_1\right) = \{\mathfrak{p}_1\}$$

 Now suppose we have already proved the claim for all modules with filtrations of length less than n. That is we have $\mathrm{Sann}(M_{n-1}) = \{\mathfrak{p}_1, \ldots, \mathfrak{p}_{n-1}\}$ by induction hypothesis and then we find

$$\begin{aligned} \mathrm{Sann}(M) &= \mathrm{Sann}(M_n) \subseteq \mathrm{Sann}(M_{n-1}) \cup \mathrm{Sann}\left(M_n \big/ M_{n-1}\right) \\ &= \mathrm{Sann}(M_{n-1}) \cup \mathrm{Sann}\left(R \big/ \mathfrak{p}_n\right) \subseteq \{\mathfrak{p}_1, \ldots, \mathfrak{p}_{n-1}\} \cup \{\mathfrak{p}_n\} \end{aligned}$$

- For the inclusion $\{\mathfrak{p}_1, \ldots, \mathfrak{p}_n\} \subseteq \mathrm{Supp}(M)$ we start with any $i \in 1 \ldots n$: By property (2) there is some isomorphism $\Phi_i : M_i/M_{i-1} \xrightarrow{\sim} R/\mathfrak{p}_i$ such that we may pick up $x_i \in M_i \subseteq M$ such that $\Phi_i(x_i + M_{i-1}) = 1 + \mathfrak{p}_i$. If now $a \in \mathrm{ann}(x_i)$ then $ax_i = 0$ such that $ax_i + M_{i-1} = 0 + M_{i-1}$ and

$$a + \mathfrak{p}_i = a(1 + \mathfrak{p}_i) = a\,\Phi_i(x_i + M_{i-1}) = \Phi_i(ax_i + M_{i-1}) = \Phi_i(0 + M_{i-1}) = 0 + \mathfrak{p}_i$$

such that $a \in \mathfrak{p}_i$. As $a \in \operatorname{ann}(x_i)$ has been arbitrary, this means $\operatorname{ann}(x_i) \subseteq \mathfrak{p}_i$ and thereby $\mathfrak{p}_i \in \operatorname{Supp}(M)$ according to the definition of the support of M.

- In the last step we will prove that the x_i constructed in the step before generate M. In particular this means $\operatorname{rank}(M) \leq n$. So consider any $y \in M = M_n$. Then $\Phi_n(y + M_{n-1}) = a_n + \mathfrak{p}_n$ for some $a_n \in R$. Then we define $y_{n-1} := y - a_n x_n$ and find that

$$\Phi_n\left(y_{n-1} + M_{n-1}\right) \;=\; \Phi_n\left(y + M_{n-1}\right) - a_n \Phi_n\left(x_n + M_{n-1}\right) \;=\; \left(a_n + \mathfrak{p}_n\right) - a_n\left(1 + \mathfrak{p}_n\right) \;=\; 0 + \mathfrak{p}_n$$

 In particular we have $y_{n-1} + M_{n-1} = 0 + M_{n-1}$ which is $y_{n-1} \in M_{n-1}$. Continuing that way we recursively construct $y_k \in M_k$ (where $k \geq j$) and $a_k \in R$ (where $k \geq j+1$) such that $y_{k-1} := y_k - a_k x_k$. Then we continue with picking up any $a_j \in R$ such that $\Phi_j(y_j + M_{j-1}) = a_j + \mathfrak{p}_j$ and let $y_{j-1} := y_j - a_j x_j$ again. We then conclude $y_{j-1} \in M_{j-1}$ in exactly the same way, as for $j = n$. In particular $y_0 \in M_0 = 0$ such that $0 = y_1 - a_1 x_1$. That is we end up with $y_1 = a_1 x_1$ and now work our way up again: We claim that $y_j = a_1 y_1 + \cdots + a_j + x_j$ and proceed inductively: From $y_{j-1} := y_j - a_j x_j$ we get $y_j = y_{j-1} + a_j x_j$ and by induction hypothesis $y_{j-1} = a_1 y_1 + \cdots + a_{j-1} + x_{j-1}$ that's it already. In the end we get $y = y_n = a_1 y_1 + \cdots + a_n x_n$ and as $y \in M$ has been arbitrary, this finishes $M \subseteq \operatorname{Lh}\{ x_1, \ldots, x_n \} \subseteq M$.

□

Proof of (5.16):

(i) We start with (a) $\implies$ (b): By (5.8.(vii)) $\operatorname{zd}(M)$ is the grand union of $\operatorname{Sann}(M)$ and by (5.14) this is a finite set. That is $\mathfrak{a}$ is contained in a union of finitely many prime ideals. By prime avoidance (2.14.(iii)) we find that $\mathfrak{a}$ already is contained in one of them and this is (b).

So for (b) $\implies$ (c): Let $\mathfrak{p} = \operatorname{ann}(x)$ for some $x \neq 0$. Then $\mathfrak{a} \subseteq \mathfrak{p} = \{ a \in R \mid ax = 0 \}$ translates into: For all $a \in \mathfrak{a}$ we have $ax = 0$ and hence $\mathfrak{a}x = \{0\}$, which is (c).

Of course (c) $\implies$ (d) is trivial so we close the circle, proving (d) $\implies$ (a): By assumption for any $a \in \mathfrak{a}$ there is some $x \neq 0$ such that $a \in \operatorname{ann}(x) \in \operatorname{Anns}(M)$. That is $\mathfrak{a}$ is contained in the grand union of $\operatorname{Anns}(M)$. But by (5.7.(iii)) this is $\operatorname{zd}(M)$ already.

(ii) Let us first prove (a) $\implies$ (b): By assumption for any $\mathfrak{p} \in \operatorname{Sann}(M)$ we have $\mathfrak{a} \subseteq \mathfrak{p}$ such that $\mathfrak{p} \in \mathbb{V}(\mathfrak{a})$. Conversely (b) $\implies$ (a): Any $\mathfrak{p} \in \operatorname{Sann}(M)$ is contained in $\mathbb{V}(\mathfrak{a})$ such that $\mathfrak{a} \subseteq \mathfrak{p}$. As this is true for any $\mathfrak{p} \in \operatorname{Sann}(M)$ we conclude that $\mathfrak{a}$ is contained in the grand intersection of $\operatorname{Sann}(M)$. It remains to verify (a) $\iff$ (c): By (5.13) the grand intersection of $\operatorname{Sann}(M)$ is the same, as the grand intersection of $\operatorname{Supp}(M)$. Thus by the same reasoning as for $\operatorname{Sann}(M)$ we find

$$\mathfrak{a} \;\subseteq\; \bigcap \operatorname{Supp}(M) \;=\; \bigcap \operatorname{Sann}(M) \quad\iff\quad \operatorname{Supp}(M) \;\subseteq\; \mathbb{V}(\mathfrak{a})$$

But for $\operatorname{Supp}(M)$ we have shown the equivalence of $\operatorname{Supp}(M) \subseteq \mathbb{V}(\mathfrak{a})$ and (c) in (3.139.(vii)) already. Combining these equivalences we conclude that (a) is equivalent to (c), too

$$\operatorname{Supp}(M) \;\subseteq\; \mathbb{V}(\mathfrak{a}) \quad\iff\quad \exists\, n \in \mathbb{N} \;:\; \mathfrak{a}^n M = 0$$

(iii) The proof will feature two,t he first loop goes like (a) $\implies$ (c) $\implies$ (b) $\implies$ (a) and the second loop like (e) $\implies$ (d) $\implies$ (c) $\implies$ (e). As the loops are interlocked in (c) this grants the

equivalence. We start with (a) $\implies$ (c): Given $a \in R$ let us distinguish two cases: If $a \in \mathfrak{p}$, then $Ra \subseteq \mathfrak{p} = \bigcap \mathrm{Sann}(M)$ such that by (ii) there is some $n \in \mathbb{N}$ such that $(Ra)^n M = 0$. But clearly $(Ra)^n = Ra^n$ and $0 = Ra^n M = a^n M = \mathrm{im}(\lambda_a^n)$. In particular λ_a is nilpotent. And in case $a \notin \mathfrak{p}$ then we use (5.8.(vii)) to find $a \notin \mathfrak{p} = \bigcup \mathrm{Sann}(M) = \mathrm{zd}(M)$ which means $a \in \mathrm{nzd}(M)$. That is $ax = 0$ implies $x = 0$ and hence $\mathrm{kn}(\lambda_a) = 0$, which is the injectivity of λ_a. The most difficult part (c) $\implies$ (b) comes next: Let us denote the following subset of R

$$\mathfrak{p} \;:=\; \{\, a \in R \mid \exists\, n \in \mathbb{N} : a^n M = 0 \,\}$$

Note that $a^n M = 0$ is equivalent to $\lambda_a^n = 0$ such that $a \in \mathfrak{p}$ is equivalent to λ_a being nilpotent. In a first step we will prove, that $\mathfrak{p}$ is an ideal of R. Clearly $0 \in \mathfrak{p}$ by taking $n = 1$. Also if $b \in \mathfrak{p}$ and $a \in R$, then there is some $n \in \mathbb{N}$ such that $b^n M = 0$. But then $(ab)^n M = b^n a^n M \subseteq b^n M = 0$ such that $ab \in \mathfrak{p}$, as well. And if now a, $b \in \mathfrak{p}$, then we have $a^m M = 0$ and $b^n M = 0$ for some m, $n \in \mathbb{N}$. The binomial rule enables us to rewrite

$$\begin{aligned}(a+b)^{m+n} &= \sum_{k=0}^{m+n} \binom{m+n}{k} a^k b^{m+n-k} \\ &= b^n \sum_{k=0}^{m} \binom{m+n}{k} a^k b^{m-k} + a^m \sum_{k=m+1}^{m+n} \binom{m+n}{k} a^{k-m} b^{m+n-k}\end{aligned}$$

Thereby $(a+b)^{m+n} M \subseteq b^n M + a^m M = 0$ such that $a + b \in \mathfrak{p}$ again. Altogether, we have found $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$. Next we verify that (c) makes this ideal a prime ideal: Consider a, $b \in R$ such that $ab \in \mathfrak{p}$. If we had $a \notin \mathfrak{p}$ and $b \notin \mathfrak{p}$ then by assumption (c) both, λ_a and λ_b would be injective. But then $\lambda_{ab} = \lambda_a \lambda_b$ would be injective, too. And this contradicts $ab \in \mathfrak{p}$ (i.e. λ_{ab} being nilpotent). Hence we have $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$ which is the prime property of $\mathfrak{p}$.

It remains to prove $\sqrt{\mathrm{ann}(x)} = \mathfrak{p}$ for any $x \in M$ with $x \neq 0$. Hereby $\mathrm{ann}(x) = \{\, a \in R \mid ax = 0 \,\}$. If $a \in \mathfrak{p}$ then there is some $n \in \mathbb{N}$ such that $a^n M = 0$. In particular $a^n x = 0$ which is $a^n \in \mathrm{ann}(x)$ which turns into $a \in \sqrt{\mathrm{ann}(x)}$. That is we have shown $\mathfrak{p} \subseteq \sqrt{\mathrm{ann}(x)}$. Conversely, if $a \in \mathrm{ann}(x)$, then λ_a is not injective and hence λ_a has to be nilpotent, by (c). That is there is some $n \in \mathbb{N}$ such that $\lambda_a^n = 0$, in other words $0 = \mathrm{im}(\lambda_a^n) = a^n M$. But this is $a \in \mathfrak{p}$ such that we have $\mathrm{ann}(x) \subseteq \mathfrak{p}$. As $\mathfrak{p}$ is prime we find $\sqrt{\mathrm{ann}(x)} \subseteq \sqrt{\mathfrak{p}} = \mathfrak{p}$. Altogether $\sqrt{\mathrm{ann}(x)} = \mathfrak{p}$.

We close the first loop, by proving (b) $\implies$ (a), but this is easy: Consider any $\mathfrak{q} \in \mathrm{Sann}(M)$, in particular $\mathfrak{q} = \mathrm{ann}(x)$ for some $x \neq 0$. As $\mathfrak{q}$ is prime we have $\mathfrak{q} = \sqrt{\mathfrak{q}} = \sqrt{\mathrm{ann}(x)} = \mathfrak{p}$. That is $\mathrm{Sann}(M) \subseteq \{\, \mathfrak{p} \,\}$. But as R is noetherian and M is finitely generated we use (5.8.(vi)) once more to find $\mathrm{Sann}(M) \neq \emptyset$. Thereby we gain (a).

This has been the hard part, the second loop is far easier: We take the back door and begin with (e) $\implies$ (d): We distinguish two cases again, if $a \notin \mathrm{zd}(M)$, then by assumption (e) there is some $x \in M$ such that for any $n \in \mathbb{N}$ we have $a^n x \neq 0$. In particular $a^n M = 0$ is false for all $n \in \mathbb{N}$. In the second case we consider $a \in \mathrm{zd}(M)$, then by (e) given $x \in M$ we find some $n \in \mathbb{N}$, such that $a^n x = 0$. We have required M to finitely generated, say $M = \mathrm{Lh}\{\, x_1, \ldots, x_r \,\}$. Then for any $i \in 1 \ldots r$ we may pick up $n(i) \in \mathbb{N}$, such that $a^{n(i)} x_i = 0$. And if we let $n := \max\{\, n(1), \ldots, n(r) \,\}$ we get $a^n x_i = 0$ for any $i \in 1 \ldots r$. But as the x_i generate M we conclude $a^n M = 0$, which was required by (d).

The implication (d) $\implies$ (c) is trivial: $\mathrm{zd}(M) = \{\, a \in R \mid \exists\, x \in M \,:\, x \neq 0 \text{ and } ax = 0 \,\}$. So suppose λ_a is *not* injective, then $\mathrm{kn}(\lambda_a) \neq 0$, i.e. there is some $x \in M$ with $x \neq 0$ and $ax = 0$. But this means $a \in \mathrm{zd}(M)$. Then by assumption (d) there is some $n \in \mathbb{N}$ such that $a^n M = 0$. This of course is nothing but $\lambda_a^n = 0$, so λ_a either is injective or nilpotent.

It remains to verify (c) $\implies$ (e): Consider any $a \in R$, if λ_a is injective, then $ax = 0$ implies $x = 0$ which is $a \notin \mathrm{zd}(M)$. So suppose for all $x \in M$ there was some $n \in \mathbb{N}$, such that $a^n x = 0$. Choose any $x \neq 0$ and let m be the minimal power, such that $a^m x = 0$. In particular $m \geq 1$ and $a^{m-1}x \neq 0$. Then $\lambda_a(a^{m-1}x) = a^m x = 0$, which contradicts λ_a being injective. That is both sides of the equivalence in (e) are false. If λ_a is nilpotent, then there is some $n \in \mathbb{N}$ such that $a^n M = \mathrm{im}(\lambda_a^n) = 0$. In particular for any $x \in M$ we get $a^n x = 0$. With the same reasoning, as before we find some $y = a^{m-1}x \neq 0$ with $ay = 0$. That is $a \in \mathrm{zd}(M)$ and hence both sides of the equivalence in (e) are true.

□

Proof of (5.18):
Let us first assume, that $\mathfrak{a}$ is a primary ideal, then $\mathfrak{p}$ is a prime ideal, due to (2.90.(ii)). Now, for any $a \in R$ we regard the homothety

$$\lambda_a \,:\, {}^{R}\!\Big/_{\mathfrak{a}} \to {}^{R}\!\Big/_{\mathfrak{a}} \,:\, b + \mathfrak{a} \mapsto ab + \mathfrak{a}$$

We will prove that λ_a either is injective or nilpotent. If λ_a is injective, we are done. Else there is some $b + \mathfrak{a} \neq 0 + \mathfrak{a}$ such that $ab + \mathfrak{a} = 0 + \mathfrak{a}$. That is $b \notin \mathfrak{a}$, but $ab \in \mathfrak{a}$. As $\mathfrak{a}$ is a primary ideal, by (a), there is some $n \in \mathbb{N}$ such that $a^n \in \mathfrak{a}$. Therefore $a^n(1 + \mathfrak{a}) = 0 + \mathfrak{a}$ such that $\lambda_a^n = 0$, that is λ_n is nilpontent. This is property (c) in (5.16.(iii)). Thereby $\mathrm{Sann}(R/\mathfrak{a}) = \{\, \mathfrak{p} \,\}$, where $\mathfrak{p} = \{\, a \in R \mid \exists\, n \in \mathbb{N} : a^n(1 + \mathfrak{a}) = 0 \,\}$ which is $\mathfrak{p} = \{\, a \in R \mid \exists\, n \in \mathbb{N} : a^n \in \mathfrak{a} \,\} = \sqrt{\mathfrak{a}}$.
Conversely suppose $\mathrm{Sann}(R/\mathfrak{a}) = \{\, \mathfrak{p} \,\}$ for $\mathfrak{p} = \sqrt{\mathfrak{a}}$, then we need to show that $\mathfrak{a}$ is a primary ideal. That is we consider a, $b \in R$ with $ab \in \mathfrak{a}$ but $b \notin \mathfrak{a}$ and need to show $a \in \sqrt{\mathfrak{a}} = \mathfrak{p}$. But as $b \notin \mathfrak{a}$ we have $x = b + \mathfrak{a} \neq 0$ and hence by property (b) in (5.16.(iii)) we find $\sqrt{\mathrm{ann}(x)} = \mathfrak{p}$. Yet $ab \in \mathfrak{a}$ implies $ax = a(b + \mathfrak{a}) = 0$ such that $a \in \mathrm{ann}(x)$, in particular $a \in \mathfrak{p}$. □

Proof of (5.20):

(i) As R is noetherian and M is finitely generated, M is noetherian again. Hence $P \leq_{\mathsf{m}} M$ is finitely generated and $P \neq 0$ by assumption, such that $\mathrm{Sann}(P) \neq \emptyset$, according to (5.8.(vi)). But by (5.7.(i)) we also have $\mathrm{Sann}(P) \subseteq \mathrm{Sann}(M) = \{\, \mathfrak{p} \,\}$. Together this can only mean $\mathrm{Sann}(P) = \{\, \mathfrak{p} \,\}$.

(ii) Let us abbreviate $P := P_1 + \cdots + P_n \leq_{\mathsf{m}} M$, then we use (5.8.(ii)) on P to find that the set of associated primes of P is just $\{\, \mathfrak{p} \,\}$ again

$$\mathrm{Sann}(P) \;=\; \bigcup_{k=1}^{n} \mathrm{Sann}(P_k) \;=\; \bigcup_{k=1}^{n} \{\, \mathfrak{p} \,\} \;=\; \{\, \mathfrak{p} \,\}$$

(iii) By assumption any M/P_k is $\mathfrak{p}$-primary (for $k \in 1 \ldots n$). But from (5.8.(iv)) we hence find that the

direct sum of this residue modules is $\mathfrak{p}$-primary, too

$$\mathrm{Sann}\left(\bigoplus_{k=1}^{n} M\Big/_{P_k}\right) \;=\; \bigcup_{k=1}^{n} \mathrm{Sann}\left(M\Big/_{P_k}\right) \;=\; \bigcup_{k=1}^{n} \{\,\mathfrak{p}\,\} \;=\; \{\,\mathfrak{p}\,\}$$

Let us abbreviate $P = P_1 \cap \cdots \cap P_n$ the intersection of the P_k, then there is a monomorphsim of R-modules of the following form

$$M\Big/_{P} \;\hookrightarrow\; \bigoplus_{k=1}^{n} M\Big/_{P_k} \;:\; x+P \mapsto (x+P_k)$$

From this (5.7.(i)) implies $\mathrm{Sann}(M/P) \subseteq \{\,\mathfrak{p}\,\}$. But as M is finitely generated, so is M/P. And as $\mathrm{Sann}(M/P_1) \neq \emptyset$ there is some $x \in M$ with $x+P_1 \neq 0+P_1$. In particular $x \notin P$ such that $M/P \neq 0$, as well. As R is noetherian we get $\mathrm{Sann}(M/P) \neq \emptyset$ from (5.8.(vi)) again. And this can only be $\mathrm{Sann}(M/P) = \{\,\mathfrak{p}\,\}$.

(iv) If L and N are $\mathfrak{p}$-primary we find $\mathrm{Sann}(M) = \{\,\mathfrak{p}\,\}$, as well, since (5.8.(i)) applied to the chain $0 \to L \to M \to N \to 0$ already reads as

$$\{\,\mathfrak{p}\,\} \;=\; \mathrm{Sann}(L) \;\subseteq\; \mathrm{Sann}(M) \;\subseteq\; \mathrm{Sann}(L) \cup \mathrm{Sann}(N) \;=\; \{\,\mathfrak{p}\,\} \cup \{\,\mathfrak{p}\,\} \;=\; \{\,\mathfrak{p}\,\}$$

□

Proof of (5.22):

(i) As M is finitely generated, so is M/P. This together with R being noetherian (5.8.(iv)) implies that $\mathrm{Sann}_{(}M/P) \neq \emptyset$. It remains to prove, that there only is one associated prime of M/P: Hence we consider any two $\mathfrak{p}$, $\mathfrak{q} \in \mathrm{Sann}(M/P)$, say $\mathfrak{p} = \mathrm{ann}(x+P)$ and $\mathfrak{q} = \mathrm{ann}(y+P)$. Then we let $U := Rx+P$ and $V := Ry+P$. As $x+P \neq 0+P$ we have $x \in U$ but $x \notin P$ such that $P \subset U$. Likewise we have $P \subset V$ (as $y \in V \setminus P$) and clearly

$$P \;\subseteq\; U \cap V$$

As P is irreducible, by assumption, and $U, V \neq P$ this means $P \subset U \cap V$ and hence we may choose any $z \in U \cap V$ with $z \notin P$. That is $z+P \in U/P = (Rx+P)/U$ is of the form $z+P = ax+P$ for some $a \in R$. Suppose we had $a \in \mathfrak{p} = \mathrm{ann}(x+P)$, then $z+P = ax+P = a(x+P) = 0+P$ in contradiction, to $z \notin P$. Thus $a \notin \mathfrak{p} = \mathrm{ann}(x+P)$ and as $\mathfrak{p}$ is prime (3.24.(ii)) implies

$$\mathrm{ann}(z+P) \;=\; \mathrm{ann}(ax+P) \;=\; \mathrm{ann}(x+P) \;=\; \mathfrak{p}$$

In complete analogy we find $\mathrm{ann}(z+P) = \mathrm{ann}(y+P) = \mathfrak{q}$ such that both $\mathfrak{p}$ and $\mathfrak{q}$ equal $\mathrm{ann}(z+P)$. In particular $\mathfrak{p} = \mathfrak{q}$. That is $\mathrm{Sann}(M/P)$ is non-empty, but all its elements are identical, meaning it only contains a single element.

(ii) Consider the set of all sub-modules of R, that do *not* have an irreducible decomposition. We claim that this set is empty. Suppose this was not the case, i.e. there was a sub-module that has no irreducible decomposition. As M is a noetherian module, there then would be a *maximal* element

in this set. Let $N \leq_{\mathsf{m}} M$ be such a sub-module, that is maximal among the sub-modules of M without irreducible decomposition.

In particular N cannot be irreducibe itself, as then $P_1 = N$ would be an irreducible decomposition. Therefore there are sub-modules P, $Q \leq_{\mathsf{m}} M$ such that $N = P \cap Q$ but $P \neq N$ and $Q \neq N$. Therefore we have $N \subset P$ and $N \subset Q$. But by maximality of N this means that P and Q *do* have an irreducible decomposition, say $P = P_1 \cap \cdots \cap P_r$ and $Q = Q_1 \cap \cdots \cap Q_s$. But then N

$$N \;=\; P \cap Q \;=\; P_1 \cap \cdots \cap P_r \cap Q_1 \cap \cdots \cap Q_s$$

also has an irreducible decomposition. This clearly is a contradiction that can only be evaded, if there is no sub-module of M that does not have an irreducible decomposition, in the first place.

(iii) Pick up an irreducible decomposition $L = Q_1 \cap \cdots \cap Q_n$ of L, which exists, according to (ii). We may scratch all Q_i from this list that are not really required for L. That is we may assume this decomposition to be minimal in the sense, that for any $i \in 1 \ldots n$ we get

$$L \;\subset\; \bigcap_{i \neq j} Q_i$$

Next we note that due to (i) any Q_i is coprimary in M, that is for any $i \in 1 \ldots n$ there is some $\mathfrak{q}_i \in \operatorname{Spec}(R)$ such that $\operatorname{Sann}(M/Q_i) = \{ \mathfrak{q}_i \}$. Now, for any $\mathfrak{p} \in \operatorname{Spec}(R)$, we may define

$$\begin{aligned} I(\mathfrak{p}) &:= \{ i \in 1 \ldots n \mid \mathfrak{q}_i = \mathfrak{p} \} \\ \mathcal{S} &:= \{ \mathfrak{p} \in \operatorname{Spec}(R) \mid I(\mathfrak{p}) \neq \emptyset \} \end{aligned}$$

That is $\mathcal{S}$ is the set of prime ideals of R, that occur as associated prime ideals of the decomposition Q_i. Clearly $s := \#\mathcal{S} \leq n$ such that $\mathcal{S}$ is finite. Choose an arbitrary numbering $\mathcal{S} = \{ \mathfrak{p}_1, \ldots, \mathfrak{p}_s \}$ of this set, then for any $j \in 1 \ldots s$ we define

$$P_j \;:=\; \bigcap_{i \in I(\mathfrak{p}_j)} Q_i$$

That is P_j is the intersection of all Q_i who belong to the same associated prime ideal $\mathfrak{q}_i = \mathfrak{p}_j$. As such P_j is $\mathfrak{p}_j$-coprimary in M, according to (5.20.(iii)) - this is property (3). And by construction, different P_j have different associated prime ideals $\mathfrak{p}_j$ - that is property (4). Also we have property (1), as we have just rearranged the intersection of the Q_i

$$L \;=\; Q_1 \cap \cdots \cap Q_n \;=\; \bigcap_{j=1}^{s} \bigcap_{i \in I(\mathfrak{p}_j)} Q_i \;=\; \bigcap_{j=1}^{s} P_j$$

But by minimality of the Q_i we also get property (2): For ease of notation say we had $L = P_2 \cap \cdots \cap P_s$, then we would be missing those Q_i that belonged to $\mathfrak{q}_i = \mathfrak{p}_1$, in particular

$$\bigcap_{j \neq 1} P_j \;=\; \bigcap_{\mathfrak{q}_i \neq \mathfrak{p}_1} Q_i \;\supset\; L$$

(iv) Using (3.125.(i)) we find an isomorphy of the $U^{-1}R$-modules $U^{-1}M/U^{-1}P_i$ and $U^{-1}(M/P_i)$. And by (5.12.(ii)) there is a 1:1 correspondence of the associated prime ideals, of the form

$$\begin{aligned}\mathrm{Sann}_{U^{-1}R}\left(U^{-1}M\Big/U^{-1}P_i\right) &= \mathrm{Sann}_{U^{-1}R}\left(U^{-1}\left(M\Big/P_i\right)\right)\\ &\longleftrightarrow \left\{\mathfrak{p}\in\mathrm{Sann}_R\left(M\Big/P_i\right)\mid \mathfrak{p}\cap U=\emptyset\right\}\end{aligned}$$

By assumption (iii) $\mathrm{Sann}(M/P_i)$ contains the single element $\mathfrak{p}_i$, therefore there only are two cases: If $\mathfrak{p}_i\cap U=\emptyset$, then then $U^{-1}M/U^{-1}P_i$ contains the single element $U^{-1}\mathfrak{p}_i$ by (5.12.(ii)). That is: $U^{-1}P_i$ is $U^{-1}\mathfrak{p}_i$-primary in $U^{-1}M$. Alternatively, if $\mathfrak{p}_i\cap U\neq\emptyset$ recall that M/P_i is $\mathfrak{p}_i$-primary. Therefore by (5.16.(iii)) we have $\sqrt{\mathrm{ann}(x+L)}=\mathfrak{p}_i$ for any $x+P_i\neq 0+P_i$. From this we find some $u\in\sqrt{\mathrm{ann}(x+L)}\cap U$, hence there is some power $n\in\mathbb{N}$ such that $u^n\in\mathrm{ann}(x+L)$, which is $u^n(x+L)=0+L=u^n(0+L)$. As U is multiplicatively closed $u^n\in U$, as well, such that $(x+L)/v=(0+L)/1$ for any $v\in U$. And as this is true, for any $v\in U$ and any $x+P_i\neq 0+P_i$ we find $U^{-1}(M/P_i)=0$, in this case. Let us summarize

$$\begin{aligned}\mathfrak{p}_i\cap U=\emptyset &\iff \mathrm{Sann}_{U^{-1}R}\left(U^{-1}M\Big/U^{-1}P_i\right)=\left\{U^{-1}\mathfrak{p}_i\right\}\\ \mathfrak{p}_i\cap U\neq\emptyset &\iff U^{-1}M\Big/U^{-1}P_i=0\end{aligned}$$

In particular this is property (3) of the reduced primary decomposition of $U^{-1}L$. And by (2.129) $\mathfrak{p}\mapsto U^{-1}\mathfrak{p}$ is a 1:1 correspondence between the prime ideals $\mathfrak{p}$ of R with $\mathfrak{p}\cap U=\emptyset$ and the prime ideals of $U^{-1}R$. Therefore, as the $\mathfrak{p}_i$ are pairwise distinct, so are the $U^{-1}\mathfrak{p}_i$ and this also is property (4) of a reduced primary decomposition. Now, as in (3.127) let us denote $k:P\mapsto U^{-1}P$ the surjective map, that turns R-sub-modules of M into $U^{-1}R$-sub-modules of $U^{-1}M$. We have also seen there, that k respects finite intersections, that is

$$k(L)=k\left(\bigcap_{i=1}^{s}P_i\right)=\bigcap_{i=1}^{s}k(P_i)$$

But as we have argued above, whenever $\mathfrak{p}_i\cap U\neq\emptyset$ we have $U^{-1}M/U^{-1}P_i=0$ and hence $k(P_i)=U^{-1}P_i=U^{-1}M$, such that these $k(P_i)$ do not contribute to the intersection. That is we find property (1) of reduced primary decompositions

$$U^{-1}L=\bigcap_{\mathfrak{p}_i\cap U=\emptyset}U^{-1}P_i$$

It remains to verify property (2): To do this we prove that for any P_i with $\mathfrak{p}_i\cap U=\emptyset$ we have $\overline{k}k(P_i)=P_i$. As we have seen in (3.127) it suffices to show the following: Consider any $x\in M$ and any $u\in X$ such that $ux\in P_i$, then we have to show $x\in P_i$. Now $ux\in P_i$ means $u\in\mathrm{ann}(x+P_i)$ and as before we have $\mathrm{ann}(x+P_i)\subseteq\sqrt{\mathrm{ann}(x+P_i)}=\mathfrak{p}_i$ which is $u\in\mathfrak{p}_i$ such that $u\in\mathfrak{p}_i\cap U=\emptyset$. From this contradiction we conclude $\overline{k}k(P_i)=P_i$.

For ease of notation say the sub-modules with $\mathfrak{p}_i\cap U=\emptyset$ are $U^{-1}P_i$ where $i\in 1\ldots r$ and for

$r < i \leq s$ we have $U^{-1}P_i = U^{-1}M$. Property (3) of reduced primary decompositions then reads as

$$\forall\, j \in 1 \ldots r \quad : \quad \bigcap_{i \neq j} U^{-1}P_i \;\neq\; U^{-1}L$$

By symmetry of the argument it suffices to regard the case $j = 1$. $U^{-1}P_2 \cap \cdots \cap U^{-1}P_r = U^{-1}L$ is equivalent to $U^{-1}P_2 \cap \cdots \cap U^{-1}P_r \subseteq U^{-1}P_1$ according to (0.1). But as for any $i \in 1 \ldots r$ we have $\bar{k}k(P_i) = P_i$ and $\bar{k}$ respects intersections we would then get

$$P_2 \cap \cdots \cap P_r \;=\; \bar{k}k(P_2) \cap \cdots \cap \bar{k}k(P_2) \;=\; \bar{k}\,(k(P_2) \cap \cdots \cap k(P_r)) \;\subseteq\; \bar{k}k(P_r) \;=\; P_r$$

This again is equivalent to $P_1 \cap \cdots \cap P_r = P_2 \cap \cdots \cap P_r$. But then we could omit P_1 in the primary decomposition of $L = P_1 \cap \cdots \cap P_s$. But as this decomposition is reduced, this cannot be. We conclude that the decomposition $U^{-1}L = U^{-1}P_1 \cap \cdots \cap U^{-1}P_r$ satisfies property (2) of reduced primary decompositions, as well.

□

Proof of (5.23):

(i) An $M/L \to M/P_i : x + L \mapsto x + P_i$ is well-defined, as $L \subseteq P_i$. Thus $x + L \mapsto (x + P_i)$ is a well-defined homomorphism of R-modules. But the injectivity is easy to see: If $(x + P_i) = (0 + P_i)$, then for any $i \in 1 \ldots n$ we have $x \in P_i$ such that $x \in P_1 \cap \cdots \cap P_s = L$. Again this is $x + L = 0 + L$.

(ii) Due to (i) and (5.7.(i)) the associated prime spectrum of M/L is contained in the associated prime spectrum of the direct sum of the M/P_i. But by (5.8.(iv)) this is

$$\mathrm{Sann}\left(M\big/_L\right) \;\subseteq\; \mathrm{Sann}\left(\bigoplus_{i=1}^{s} M\big/_{P_i}\right) \;=\; \bigcup_{i=1}^{s} \mathrm{Sann}\left(M\big/_{P_i}\right) \;=\; \bigcup_{i=1}^{s} \{\,\mathfrak{p}_i\,\}$$

Thus we have $\mathrm{Sann}(M/L) \subseteq \{\,\mathfrak{p}_1, \ldots, \mathfrak{p}_s\,\}$. For the converse inclusion we prove $\mathfrak{p}_1 \in \mathrm{Sann}(M/L)$. Due to the symmetry of the argument this does suffice. To do this regard

$$\varphi \;:\; P_2 \cap \cdots \cap P_s\big/_L \to M\big/_{P_1} \;:\; x + L \mapsto x + P_i$$

As $L \subseteq P_1$ this is a well-defined R-module homomorphism. And given $x \in P_2 \cap \cdots \cap P_s$ with $x + P_1 = 0 + P_1$ we had $x \in P_1$ as well, such that $x \in P_1 \cap (P_2 \cap \cdots \cap P_s) = L$. Thus $x + L = 0 + L$, which is the injectivity of φ. Yet, as the P_i are a *reduced* decomposition of L, we have $L \subset P_2 \cap \ldots P_s$ that is there is some $x \in P_2 \cap \ldots P_s$ with $x \notin L$. Therefore $(P_2 \cap \ldots P_s)/L \neq 0$ is not the zero-module. Thus by (5.8.(vi)) $\mathrm{Sann}((P_2 \cap \ldots P_s)/L) \neq \emptyset$, yet as φ is injective

$$\emptyset \;\neq\; \mathrm{Sann}\left(P_2 \cap \cdots \cap P_s\big/_L\right) \;\subseteq\; \mathrm{Sann}\left(M\big/_{P_1}\right) \;=\; \{\,\mathfrak{p}_1\,\}$$

such that we conclude $\mathrm{Sann}((P_2 \cap \cdots \cap P_s)/L) = \{\,\mathfrak{p}_1\,\}$ once more. But as $(P_2 \cap \cdots \cap P_s)/L$ is a sub-module of M/L this implies $\mathfrak{p}_1 \in \mathrm{Sann}(M/L)$, too - all by (5.7.(i)) - and as we could have done this with any $i \in 1 \ldots s$ we see $\{\,\mathfrak{p}_1, \ldots, \mathfrak{p}_s\,\} \subseteq \mathrm{Sann}(M/L)$, as well.

(iii) Suppose $\mathfrak{p}_k$ is minimal and take $U := R \setminus \mathfrak{p}_k$. Suppose we have $\mathfrak{p}_i \cap U = \emptyset$, then we had $\mathfrak{p}_i \subseteq \mathfrak{p}_k$ and as $\mathfrak{p}_k$ is minimal, this is $\mathfrak{p}_i = \mathfrak{p}_k$. Now, as the $\mathfrak{p}_i$ are pairwise distinct, this implies $i = k$. Thus

we have $\mathfrak{p}_i \cap U = \emptyset$ is and only if $i = k$. By (5.22.(iv)) we have a reduced primary decomposition of $U^{-1}L$, given by

$$\left\{ U^{-1}P_i \mid i \in 1 \ldots s, \mathfrak{p}_i \cap U = \emptyset \right\} \;=\; \left\{ U^{-1}P_k \right\}$$

In particular $U^{-1}L = U^{-1}P_k$ (considered, as subsets of $U^{-1}M$). Also we have seen there, that P_k is $\kappa^{-1}(U^{-1}P_k) = \kappa^{-1}(U^{-1}L)$ - in the proof of (5.22.(iv)) we have used the notation $P_k = \bar{k}k(L)$. But by (3.127) this already is given, to be

$$P_k \;=\; \bar{k}k(L) \;=\; \{ x \in M \mid \exists\, u \in U \,:\, ux \in L \}$$

We could end here, as in particular P_k is uniquely determined by L, but in literature this usually is given as the kernel of $x + L \mapsto (x + L)/1$. So when do we get $(x + L)/1 = (0 + L)/1$? Clearly iff there is some $u \in U$ such that $u(x + L) = u(0 + L) = 0 + L$, which is $ux \in L$. And this is precisely the condition in the set $\bar{k}k(L)$ above.

□

Proof of (5.26):
Item (i) is purely definitional, there is nothing to prove. In (ii) we claim that for an integral domain R the hull $\mathrm{Hull}(P)$ is a sub-module of M again: Thus consider $x, y \in \mathrm{Hull}(P)$ and $r \in R$. By definition there are some $a, b \in R$ such that $a, b \neq 0$ and $ax \in P$ and $by \in P$. But then $a(rx) = r(ax) \in P$ again, such that $rx \in \mathrm{Hull}(P)$, as well. And $(ab)(x + y) = b(ax) + a(by) \in P$ is plain, as well. As $a, b \neq 0$ and R is an integral domain we have $ab \neq 0$ and thereby $x + y \in \mathrm{Hull}(P)$ again. If $p \in P$, then $1p \in P$ and as R is an integral domain we have $1 \neq 0$. Therefore we have the inclusion $P \subseteq \mathrm{Hull}(P)$. Now if $x \in \mathrm{tor}(M)$ is a torsion element, then by definition there is some $a \in R$ with $a \neq 0$ such that $ax = 0 \in P$. Thus we also have $\mathrm{tor}(M) \subseteq \mathrm{Hull}(P)$. And as $\mathrm{Hull}(P)$ is a sub-module this implies $P + \mathrm{tor}(M) \subseteq \mathrm{Hull}(P)$.

In item (iii) we have to check the well-definedness of the content: First of all - as $M \neq 0$ the basis is non-empty $I \neq \emptyset$ and thus we may apply the greatest common divisor. So let us check the independence of the basis: If $\{ m_i \mid i \in I \}$ is a basis with $x = \sum_i a_i m_i$ and $\{ n_i \mid i \in I \}$ is a basis with $x = \sum_i b_i n_i$ then let us denote $A := \{ a_i \mid i \in I \}$ and $B := \{ b_i \mid i \in I \}$ respectively. We need to verify that $\gcd(A) = \gcd(B)$. To do this let

$$m_i \;=\; \sum_{j \in I} a_{i,j} n_j$$

for any $i \in I$. If now $c \in \gcd(A)$ and $d \in \gcd(B)$, in particular $c \mid a_i$ for any $i \in I$. Then we have $a_i = ca'_i$ for some $a'_i \in R$ and thereby

$$x \;=\; \sum_{i \in I} a_i m_i \;=\; \sum_{i \in I} ca'_i \sum_{j \in I} a_{i,j} n_j \;=\; \sum_{j \in I} c \left(\sum_{i \in I} a'_i a_{i,j} \right) n_j$$

As the n_j form a basis we can compare coefficients to find $b_j = c \sum_i a'_i a_{i,j}$ such that $c \mid b_j$ for any $j \in I$. This is $c \mid B$ and as d is a greatest common divisor of B this implies $c \mid d$. In complete analogy we find $d \mid c$ such that c and d are associate $c \approx d$. This again implies

$$\gcd(A) \;=\; cR^* \;=\; dR^* \;=\; \gcd(B)$$

□

Proof of (5.28):

(i) Let us start with $x_0 := x$ and $a_0 := 1$. We will recursively construct $x_n \in M$ and $a_n \in R$ such that $x = a_n x_n$, $\operatorname{ann}(x_n) = 0$ and

$$Rx_0 \subset Rx_1 \subset \ldots \subset Rx_n$$

For $n = 0$ everything is granted, so suppose we already have x_n and a_n. If x_n is primitive, then we are done, as we can take $p := x_n$ and $a := a_n$. If x_n is not primitive, then there are some $b \in R$ and $y \in M$ such that $x_n = by$ and $b \notin R^*$. We will now prove that $Rx_n \subset Ry$: First of all $ax_n = aby \in Ry$ such that $Rx_n \subseteq Ry$ is clear. And since $\operatorname{ann}(x_n) = 0$ we also have $\operatorname{ann}(y) = 0$: If we have $ay = 0$ then $ax_n = aby = bay = b0 = 0$ such that $a = 0$. Suppose we even had the equality $Rx_n = Ry$, then $y \in Rx_n$ would mean $y = ax_n = aby$ for some $a \in R$. But this is $(1 - ab)y = 0$ and thereby $1 - ab = 0$, as $\operatorname{ann}(y) = 0$. But $1 = ab$ would imply $b \in R^*$ which is untrue. Thus we have $y \notin Rx_n$ and thereby $Rx_n \subset Ry$. Now we may take $x_{n+1} := y$ and $a_{n+1} := a_n b$ then $a_{n+1}x_{n+1} = a_n by = a_n x_n = x$.

Thus we have seen: If x_n is not primitive, then we may append the strictly increasing chain $Rx_0 \subset Rx_1 \subset \ldots \subset Rx_n$ by another link $Rx_n \subset Rx_{n+1}$. But as M is noetherian there is no infinitely ascending chain of sumbodules, so this has to stop at some point $m \in \mathbb{N}$. But this only is the case if x_m is primitive and $x = a_m x_m$.

(ii) Let $\{ m_i \mid i \in I \}$ be a basis of M and let $A := \{ a_i \mid i \in I \} \subseteq R$ be the coefficients of the basis representation of x, that is

$$x = \sum_{i \in I} a_i m_i$$

If $c \in \operatorname{cont}(x) = \gcd(A)$ then for any $i \in I$ there is some $a_i' \in R$ such that $a_i = ca_i'$ and thereby we find x in the form

$$x = cp \quad \text{where} \quad p = \sum_{i \in I} a_i' m_i$$

We will now prove $1 \in \operatorname{cont}(x) \implies x$ primitive: We have to regard $b \in R$ and $y \in M$ such that $x = by$. Writing $y = \sum_i b_i m_i$ we find

$$\sum_{i \in I} a_i m_i = x = by = \sum_{i \in I} bb_i\, m_i$$

such that $a_i = bb_i$ for any $i \in I$ by comparing coefficients. In particular $b \mid A$ such that $b \mid c = \gcd(A)$. But as $1 \in \operatorname{cont}(x) = cR^*$ we have $c \in R^*$ and then $b \mid c$ implies $b \in R^*$ such that x truly is primitive. As $1 \in \operatorname{cont}(p)$ by construction this already implies that p is primitive. Conversely for x primitive $\implies 1 \in \operatorname{cont}(x)$ we may use $x = cp$ to find $c \in R^*$ and hence $1 \in cR^* = \operatorname{cont}(x)$.

(iii) We will distinguish several cases: First of all, if $\dim(M) = 1$, then there is a basis $\{ y_1 \}$ of M. As $p \in M = Ry_1$ we get $p = ay_1$ for some $a \in R$. But as p is primitive we get $a \in R^*$. And this means $x \mapsto ax$ is an automorphism of M that maps p to y_1. In particular $\{ p \}$ is a basis of M, as well. Next consider the case $\dim(M) = 2$, then there is a basis $\{ y_1, y_2 \}$ of M. As $p \in M = Ry_1 + Ry_2$ there are some $a, b \in R$ such that $p = ay_1 + by_2$. As p is primitive (ii) tells us, that $1 \in \gcd\{ a, b \}$.

That is there are some $u, v \in R$ such that

$$au + bv \;=\; 1$$

Now define $m_1 := p$ and $m_2 := -vy_1 + uy_2$, we will prove that $\{ m_1, m_2 \}$ is a basis of M, starting with $\mathrm{Lh}\{ m_1, m_2 \} = M$:

$$\begin{aligned} up - bm_2 &= u(ay_1 + by_2) - b(-vy_1 + uy_2) \\ &= (au + bv)y_1 + (ub - bu)y_2 \;=\; y_1 \\ vp + am_2 &= v(ay_1 + by_2) + a(-vy_1 + uy_2) \\ &= (va - av)y_2 + (bv + au)y_2 \;=\; y_2 \end{aligned}$$

Thus we have y_1 and $y_2 \in \mathrm{Lh}\{ m_1, m_2 \}$ and as these generate M we already get $M = \mathrm{Lh}\{ m_1, m_2 \}$. That is $\{ m_1, m_2 \}$ generates M. It remains to show, that $\{ m_1, m_2 \}$ also is linearly independent. Thus consider some $c, d \in R$ such that $cm_1 + dm_2 = cp + dm_2 = 0$. That is

$$\begin{aligned} c(ay_1 + by_2) + d(-vy_1 + uy_2) &= 0 \\ (ac - dv)y_1 + (bc + du)y_2 &= 0 \end{aligned}$$

As $\{ y_1, y_2 \}$ is a basis and hence linearly independent we find the following system of linear equations, as the coefficients in front of y_1 and y_2 have to vanish

$$\begin{aligned} ac - dv &= 0 \\ bc + du &= 0 \end{aligned}$$

Multiplying the upper equation with u, the lower with v and then adding the results leads to $0 = acu - duv + bcv + duv = (au + bv)c = c$ and multiplying the upper equation with $-b$, the lower with a and then adding the results leads to $0 = -abc + bdv + abc + adu = (bv + au)d = v$. Thus we found $c = 0$ and $d = 0$ which means that $\{ m_1, m_2 \}$ is a basis of M that contains p, as $p = m_1$.

(iii) Next we consider the case $\dim(M) < \infty$, that is M is finitely generated. Let $n := \dim(M)$, by induction we may assume, that the statement is true for all modules of rank $n - 1$ or lower. So pick up a basis $\{ y_1, \ldots, y_n \}$ of M and define $Q := \mathrm{Lh}\{ y_1, \ldots, y_{n-1} \} \leq_{\mathfrak{m}} M$. Then we clearly have

$$M \;=\; Q \oplus Ry_n$$

Let $p = \sum_i a_i y_i$ be the representation of p in this basis. If $a_n = 0$ then $p \in Q$ and as $\dim(Q) = n - 1 < n$ this would mean there is some basis $\{ m_1, \ldots, m_{n-1} \}$ of Q that contains p. But then $\{ m_1, \ldots, m_{n-1}, y_n \}$ would be a basis of M containing p, which we needed to find. So this case is done and we continue with $a_n \neq 0$. Now let

$$y \;:=\; p - a_n y_n \;=\; \sum_{i=1}^{n-1} a_i y_i \;\in\; Q$$

If $y = 0$, then $p = a_n y_n$ and by the case $n = 1$ above this would mean, that p is a basis of Ry_n. In particular $\{ y_1, \ldots, y_{n-1}, p \}$ would be a basis of M containing p. So this case is done, as well and we continue with $y \neq 0$. Then by (ii) there is some primitive $q \in Q$ such that $y = bq$ where $b = \mathrm{cont}(y) = \gcd\{ a_1, \ldots, a_{n-1} \}$. By induction hypothesis there is a basis $\{ m_1, \ldots, m_{n-1} \}$ of Q containing Q. Without loss of generality we have $q = m_1$. Then $\{ q, m_2, \ldots, m_{n-1}, y_n \}$ is a basis of M and we have

$$M \;=\; \mathrm{Lh}\{ m_2, \ldots, m_{n-1} \} \oplus \mathrm{Lh}\{ q, y_n \}$$

Note that $p = y + a_n y_n = bq + a_n y_n$ is a basis representation of p in that basis. And as p is primitive we therefore have $1 \in \mathrm{cont}(p) = \gcd\{ b, a_n \}$. Let $P := \mathrm{Lh}\{ q, y_n \}$, as p is primitive and $\dim(P) = 2$ the case $n = 2$ above tells us that there is a basis $\{ p, m_n \}$ of P. That is we can exchange $P = \mathrm{Lh}\{ q, y_n \}$ in the above inner direct sum by $\mathrm{Lh}\{ p, m_n \}$ and thereby get a basis $\{ p, m_2, \ldots, m_{n-1}, m_n \}$ of M that contains p. Thus item (iii) is proved for any finitely generated, free module M.

(iii) Now if M is not finitely generated $\dim(M) = \infty$, then we still pick up a basis $\{ y_i \mid i \in I \}$ of M. Then there is a *finite* subset $\Omega \subseteq I$ such that $p \in M$ has the basis representation

$$p \;=\; \sum_{i \in \Omega} a_i y_i$$

Now let $P := \mathrm{Lh}\{ y_i \mid i \in \Omega \}$ and $Q := \mathrm{Lh}\{ y_j \mid j \in I \setminus \Omega \}$, then it is clear that $p \in P$ and $M = P \oplus Q$. As P is finitely generated and free, we already know that there is a basis $\{ m_i \mid i \in \Omega \}$ of P containing p. But then we have found a basis of M containing p, namely

$$p \;\in\; \{ m_i \mid i \in \Omega \} \cup \{ y_j \mid j \in I \setminus \Omega \}$$

(iv) Let $n := \mathrm{rank}(P)$, by assumption P is finitely generated and hence $n \in \mathbb{N}$, such that we can use induction on n. But first of all, if $n = 0$ then $P = 0$ and there is nothing to prove. If $n = 1$, then there is a basis $\{ x \}$ of P and we write $x = dp$ for $d = \mathrm{cont}(p)$ and some primitive $p \in M$. Then by (iii) there is a basis $\{ m_i \mid i \in I \}$ of M that contains $p \in \{ m_i \mid i \in I \}$. Letting $p_1 := p$ and $d_1 := d$ this already is property (1) and property (2) is void in the case $n = 1$. Thus $n = 1$ is complete and we may proceed with $n \geq 2$:

For $n \geq 2$ we start with $M_1 := M$ and $P_1 := P$ and consider the following set $\mathcal{A}$ of ideals in R. Thereby $\mathrm{cont}(x)R$ denotes the ideal generated by $\mathrm{cont}(x) \subseteq R$. Yet if $c \in \mathrm{cont}(x)$ then $\mathrm{cont}(x)R = cR$, as $\mathrm{cont}(x) = cR^* \subseteq cR$. Thus we have $\mathrm{cont}(x)R = \mathrm{cont}(y)R$ if and only if $\mathrm{cont}(x) = \mathrm{cont}(y)$. Now let

$$\mathcal{A} \;:=\; \{ \mathrm{cont}(x)R \mid x \in P,\, x \neq 0 \}$$

Note that R is a PID and hence a noetherian ring such that $\mathcal{A}$ contains a maximal element. Let $x \in P_1 = P$ be an element, such that $dR = \mathrm{cont}(x)R \in \mathcal{A}^*$ is maximal. As $x \neq 0$ we may write $x = dp$ for some primitive $p \in M$ according to (ii). And by (iii) there is a basis $\mathcal{M}_1 := \{ m_j \mid j \in J \}$ of $M_1 = M$ such that $p \in \mathcal{M}_1$. Take $\mathcal{M}_2 := \mathcal{M}_1 \setminus \{ p \}$ and $M_2 := \mathrm{Lh}(\mathcal{M}_2)$. That is: If $p = m_k$

for some $k \in J$ then we have $\mathcal{M}_2 = \{ m_i \mid i \in I \}$ where $I := J \setminus \{ k \}$. Then

$$M_1 \;=\; M \;=\; Rp \oplus M_2$$

Also let $P_2 := P \cap M_2 \;\leq_{\mathsf{m}}\; M_2$. The central part of this proof is to establish the following inner direct sum

$$P_1 \;=\; P \;=\; Rx \oplus P_2$$

First of all we have $x = dp$ and hence $Rx = Rdp \subseteq Rp$. And by also $P_2 \subseteq M_2$ by construction. Therefore we have $Rx \cap P_2 \subseteq Rp \cap M_2 = 0$ such that $Rx \cap P_2 = 0$. So for now we have to prove $P_1 = Rx + P_2$. To do this consider any $y \in P_1$ and use a basis representation of y in terms of $\mathcal{M}_1 = \{ p \} \cup \mathcal{M}_2$:

$$y \;=\; cp + \sum_{i \in I} a_i m_i$$

Let $b \in \gcd\{ c, d \}$, then there are some $u, v \in R$ such that $b = uc + vd$. If $z := ux + vy$ then z has the following representation in $\mathcal{M}_1$

$$\begin{aligned} z \;&=\; ux + vy \;=\; udp + vy \\ &=\; (ud + vc)p + \sum_{i \in I} va_i m_i \;=\; bp + \sum_{i \in I} va_i m_i \end{aligned}$$

As $x \neq 0$ we have $d \neq 0$ and thereby $b \neq 0$ such that $z \neq 0$. Also note that $x \in P_1$ and $y \in P_1$ such that $z \in P_1$. So we have $\mathrm{cont}(z)R \in \mathcal{A}$ by definition of $\mathcal{A}$. But $\mathrm{cont}(z)$ is the greatest common divisor of b and the va_i, so in particular $\mathrm{cont}(z)$ divides b which divides d, that is $Rd \subseteq Rb \subseteq \mathrm{cont}(z)R$. By maximality of Rd in $\mathcal{A}$ this implies $Rd = \mathrm{cont}(z)R$ and thereby $Rd = Rb$. Thus $d \approx b \mid c$ implies $d \mid c$, say $c = dc'$ for some $c' \in R$. That is

$$y \;=\; c'x + \sum_{i \in I} a_i m_i \;\in\; Rx + M_2$$

And as $\sum_i a_i m_i = y - c'x \in P_1$ this is $\sum_i a_i m_i \in P_1 \cap M_2 = P_2$. As y has been arbitrary, this is $P_1 = Rx + P_2$ as desired. Thus we have established the decomposition of P_1 as the inner direct sum.

Now $n = \mathrm{rank}(P_1) = \mathrm{rank}(Rx \oplus P_2) = \mathrm{rank}(Rx) + \mathrm{rank}(P_2) = 1 + \mathrm{rank}(P_2)$ such that $\mathrm{rank}(P_2) = n - 1 < n$. Also $P_2 \;\leq_{\mathsf{m}}\; P_1 = P \;\leq_{\mathsf{m}}\; M_2$ and M_2 is a free R-module. So we may use the induction hypothesis to find a basis $\mathcal{Q} = \{ q_i \mid i \in I \}$ of M_2, a subset $\{ p_2, \ldots, p_n \} \subseteq \mathcal{Q}$ and scalars $\{ d_2, \ldots, d_n \} \subseteq R$ such that $\{ d_i q_i \mid i \in 2 \ldots n \}$ is a basis of P_2 and $d_{i-1} \mid d_i$ for any $i \in 3 \ldots n$. We now let $p_1 := p$ and $d_1 := d$. Then $d_1 p_1 = dp = x$ such that $\{ d_i q_i \mid i \in 1 \ldots n \}$ is a basis of $P_1 = P$. This is property (1) already. For property (2) we still have to show $d_1 \mid d_2$. To see this let $s := d_1 p_1 + d_2 p_2 \in P$. Note that this already is the representation of s in the basis $\mathcal{M}_1$ and thereby $\mathrm{cont}(s)R = \gcd\{ d_1, d_2 \}R$. As $d_1 = d \neq 0$ again, we have $s \neq 0$ such that $\mathrm{cont}(s)R \in \mathcal{A}$. But by construction $\mathrm{cont}(s)$ divides d_1 such that $dR = d_1 R \subseteq \mathrm{cont}(s)R$. By the maximality of dR in $\mathcal{A}$ again, this is $d_1 R = \mathrm{cont}(s)R$ and thereby $d_2 R \subseteq \mathrm{cont}(s)R = d_1 R$ which is $d_1 \mid d_2$. This has been the last piece to fit in and the proof is complete.

□

Proof of (5.31):

(ii) For any $j \in 1 \dots r$ let us denote the generator of the sub-module $R/d_jR \hookrightarrow T$ by t_j. That is t_j is the following element

$$t_j \;:=\; \big(\delta_{i,j} + d_iR\big) \;\in\; T$$

As $d_{i-1} \mid d_i$ for any $i \in 2 \dots r$ it is clear (by induction) that $d_i \mid d_r$ for any $i \in 1 \dots r$. Therefore we have $d_r(1 + d_iR) = d_r + d_iR = 0 + d_iR$ such that $d_r t_i = 0$ for any $i \in 1 \dots r$. As the t_i generate T this means $d_r \in \mathrm{ann}(T)$. If conversely $a \neq 0$ with $at_i = 0$ for any $i \in 1 \dots r$, then in particular $at_r = 0$. But this means $0 + d_rR = a(1 + d_rR) = a + d_rR$ such that $d_r \mid a$. In particular we get $\mathrm{ann}(T) = d_rR$.

(iii) As $d_rT = 0$ and $d_r \neq 0$ it is clear that $0^f \oplus T \subseteq \mathrm{tor}(M)$. Conversely consider any $x \in M$ such that $ax = 0$ for some $a \neq 0$. As any element $x \in M$ is of the form $x = (u, v)$ where $u \in R^f$ and $v \in T$ we in particular have $au = 0$. For $u = (u_1, \dots, u_f) \in R^f$ this means $au_i = 0$ for any $i \in 1 \dots f$. But as $a \neq 0$ and R is an integral domain, this implies $u_i = 0$ such that $u = 0$ and thereby $x = (0, v) \in 0^f \oplus T$.

(i) If we take $F := R^f \oplus 0^r \;\leq_{\mathrm{m}}\; M$ then $M = F \oplus T$. And T is generated by $\{\, t_1, \dots, t_r \,\}$ which we defined in (iii). As $d_it_i = 0$ any set $\{\, t_i \,\}$ is linearly dependent (recall $d_i \neq 0$). In particular $F \cup \{\, t_i \,\}$ is linearly dependent and hence (3.102.(v)) implies that $\mathrm{free}(M) = \dim(F) = f$.

(iv) If $r = 0$ then clearly R^f is free, as it admits the Euclidean basis. If conversely M is free, then M is torsion-free (R is an integral domain) according to (3.23.(ii)). And this implies $T = 0$ such that $r = 0$.

(v) If $f = 0$ then $d_rM = 0$ according to (iii) such that M is a torsion-module. Conversely if M is a torsion module then $M = \mathrm{tor}(M) = 0^f \oplus T$ due to (iv). Comparing this to $M = R^f \oplus T$ we find $f = 0$.

(vi) As $\{\, t_1, \dots, t_r \,\}$ generates T it is clear that $\mathrm{rank}(T) \leq r$. Now suppose $q := \mathrm{rank}(T) < r$, that is there is a set $\{\, g_1, \dots, g_q \,\} \subseteq T$ such that there is an epimorphism of R-modules

$$\gamma \;:\; R^q \;\twoheadrightarrow\; T \;:\; (a_1, \dots, a_q) \;\mapsto\; \sum_{k=1}^{q} a_k q_k$$

In particular for any $i \in 1 \dots r$ there has to be some $u_i \in R^q$ such that $t_i = \gamma(u_i)$. Now regard the following matrix

$$U \;=\; \begin{pmatrix} | & | & & | \\ u_1 & u_2 & \dots & u_r \\ | & | & & | \end{pmatrix} \in \mathrm{mat}_{q,r}(R)$$

Then by (4.72.(i)) we have $\text{c-rank}(U) \leq q < r$ and this means that the columns of U have to be linearly dependent. In particular there are some $a_1, \dots, a_r \in R$ that are not all zero [say $a_j \neq 0$], such that

$$\sum_{i=1}^{r} a_i u_i \;=\; 0$$

We will now prove that in general, that for any $a_1, \ldots, a_r \in R$ we always have the following implication

$$\sum_{i=1}^{r} a_i u_i \;=\; 0 \quad\Longrightarrow\quad \forall\, i \in 1 \ldots r \;:\; d_1 \mid a_i$$

To see this simply compute

$$0 \;=\; \gamma\left(\sum_{i=1}^{r} a_i u_i\right) \;=\; \sum_{i=1}^{r} a_i \gamma(u_i) \;=\; \sum_{i=1}^{r} a_i t_i \;=\; \big(a_i + d_i R\big) \;\in\; T$$

This means $0 + d_i R = a_i + d_i R$ for any $i \in 1 \ldots r$ and thereby $d_i \mid a_i$. But by assumption we have $d_{i-1} \mid d_i$ for any $i \in 2 \ldots r$ such that by induction we find $d_1 \mid d_i$ for any $i \in 1 \ldots r$. Now $d_1 \mid d_i$ and $d_i \mid a_i$ together imply $d_1 \mid a_i$. That is there are some $a'_1, \ldots, a'_r \in R$ such that $d_1 a'_i = a_i$. So we have proved the implication above. But from this we also get

$$0 \;=\; \sum_{i=1}^{r} a_i u_i \;=\; d_1 \left(\sum_{i=1}^{r} a'_i u_i\right)$$

Let us abbreviate $d := d_1$ and recall that $d \neq 0$ by assumption. Then this equation can only hold true, if the sum in brackets is zero. This however enables us to repeat this construction indefinitely however and thereby arrive at a contradiction:

Starting with $c_0 := a_j$ we would find some $c_1 := a'_j \in R$ such that $c_0 = d c_1$. As we can repeat the construction there is some $c_2 \in R$ such that $c_1 = d c_2$ which again is $c_0 = d^2 c_2$. Iterating we find $c_m \in R$ such that $c_0 = d^m c_m$ for any $m \in \mathbb{N}$. That is $d^m \mid a_j \neq 0$ for any $m \in \mathbb{N}$. But $d \notin R^*$ has a prime factor, so the fact that m can be increased indefinitely contradicts the primary decomposition of a_j which only admits finitely many prime divisors. The only way to avoid this contradiction is to have $a_j = 0$ which falsifies $q < r$.

(vii) As $M = F \oplus T$ and $\operatorname{rank}(F) = f$ and $\operatorname{rank}(T) = r$ according to (vi) it is clear that $\operatorname{rank}(M) = f + r$ by construction of the direct sum.

□

Proof of (5.32):

(iii) As M is finitely generated we have $N := \operatorname{rank}(M) \in \mathbb{N}$. And as $M \neq 0$ we also have $N \geq 1$. If $\{\, x_i \mid i \in 1 \ldots N \,\} \subseteq M$ is a generating set of M, then we have an epimorphism of the form

$$\psi \;:\; R^N \;\twoheadrightarrow\; M \;:\; (b_1, \ldots, b_N) \;\mapsto\; \sum_{i=1}^{N} b_i x_i$$

Let us take $P := \operatorname{kn}(\psi) \;\leq_{\mathfrak{m}}\; R^N$, then by the first isomorphism theorem of modules (3.78.(ii)) we find an induced isomorphism

$$\Psi \;:\; R^N \big/ P \;\xrightarrow{\sim}\; M \;:\; (b_1, \ldots, b_N) + P \;\mapsto\; \sum_{i=1}^{N} b_i x_i$$

But as R^N is a free R-module we may apply (5.28.(iv)) to find a basis $\{\, m_1, \ldots, m_N \,\}$ of R^N and subsets $\{\, p_1, \ldots, p_n \,\} \subseteq \{\, m_1, \ldots, m_N \,\}$ and $\{\, d_1, \ldots, d_n \,\} \subseteq R$ such that $\{\, d_i p_i \mid i \in 1 \ldots n \,\}$ is a

basis of P and $d_{i-1} \mid d_i$ for any $i \in 2 \dots n$. Without loss of generality we may assume $p_i = m_i$ for any $i \in 1 \dots n$.

Let us now define $M_i := Rm_i \ \leq_{\mathfrak{m}} \ R^N$ for any $i \in 1 \dots N$. Then R^N is the inner direct sum of the M_i, as the m_i form a basis of R^N. Also let $P_i := Rd_i m_i \ \leq_{\mathfrak{m}} \ M_i$ for any $i \in 1 \dots n$ and $P_j := 0 \ \leq_{\mathfrak{m}} \ M_j$ for $j \in (n+1) \dots N$. Then

$$\sum_{i=1}^{N} P_i \ = \ \mathsf{Lh}\{ d_1 m_1, \dots, d_n m_n \} \ = \ P$$

Thus by (3.35) we obtain another isomorphism of R-modules, this time

$$\Phi \ : \ \bigoplus_{i=1}^{N} M_i \Big/ P_i \ \xrightarrow{\sim} \ R^N \Big/ P \ : \ (y_i + P_i) \ :\mapsto \left(\sum_{i=1}^{N} y_i \right) + P$$

Let us denote $d_i := 0$ for $i \in (n+1) \dots N$ then [as any $m_i \neq 0$ and R is an integral domain, even a PID] it is clear, that for any $i \in 1 \dots N$ we have the isomorphy $R/d_i R \xrightarrow{\sim} M_i/P_i$ of R-modules given by $a_i + d_i R \mapsto a_i m_i + P_i$. Thus we can reformulate this isomorphy, as

$$\Phi' \ : \ \bigoplus_{i=1}^{N} R \Big/ d_i R \ \xrightarrow{\sim} \ R^N \Big/ P \ : \ (a_i + d_i R) \ :\mapsto \left(\sum_{i=1}^{N} a_i m_i \right) + P$$

Note that $\sum_i a_i m_i$ is some element $(b_1, \dots, b_N)$ of R^N. Thus we can compose $\Psi\Phi'$ to find the isomorphism we desired

$$\Psi\Phi' \ : \ \bigoplus_{i=1}^{N} R \Big/ d_i R \ \xrightarrow{\sim} \ M$$

All we need to do is analyze the structure of the module on the left-hand side. If $i > n$ then we have $d_i = 0$ and hence $R/d_i R \ \cong_{\mathfrak{m}} \ R$ canonically. However these are the only d_i with $d_i = 0$, since: If we had $d_1 = 0 \in R$ then we had $d_1 p_1 = 0 \in P$ such that $\{ d_1 p_1 \}$ would be linearly dependent. As $\{ d_i p_i \mid i \in 1 \dots n \}$ is a basis of P, this cannot be and hence we know $d_i \neq 0$ for any $i \in 1 \dots n$. Thus we may take $f := N - n$ and have

$$\Psi\Phi' \ : \ \bigoplus_{i=1}^{n} R \Big/ d_i R \oplus R^f \ \xrightarrow{\sim} \ M$$

And if $d_i \in R^*$ then $d_{i-1} \in R^*$ as well: By assumption $d_{i-1} \mid d_i$ we have $d_{i-1} a_i = d_i$ for some $a_i \in R$ and hence $d_{i-1}(a_i d_i^{-1}) = 1$ such that $d_{i-1} \in R^*$ as well. By induction we see there is a maximal number $z \in \mathbb{N}$ such that $d_i \in R^*$ for any $i \leq z$ that is

$$d_i \ \in \ \begin{cases} R^* \text{ if } i \in 1 \dots z \\ R^\bullet \text{ if } i \in (z+1) \dots n \end{cases}$$

However if $d_i \in R^*$ then $R/d_i R = 0$ so we might as well omit these direct summands. And if we

define $r := n - z$ then the above isomorphism may be rewritten once more, into

$$\Psi\Phi' \; : \; \bigoplus_{i=1}^{r} R \Big/ d_{z+i}R \oplus R^f \;\; \xrightarrow{\sim} \;\; M$$

Thus renumbering the $d_i := d_{z+i}$ we have found the invariant factors of M that have all the properties we asked for. Note that since R is a PID it also is an UFD by (2.79.(ii)) and hence the additional statements concerning M are just taken from (5.31). Note that $N = \mathrm{rank}(M) = r + f = n - z + N - n = N - z$, that is $z = 0$ which means that by minimality of the generating set $\{ x_1, \ldots, x_N \}$ there are *no* $d_i \in R^*$ in the first place.

(i) By (iii) we have an isomorphism of the form [for some $r, f \in \mathbb{N}$ with $n = \mathrm{rank}(M) = f + r$ according to (5.31.(vii)) and some invariant factors $d_i \in R$ such that $d_1 \mid d_2$ until $d_{n-1} \mid d_n$]

$$\Phi \; : \; \left(\bigoplus_{i=1}^{r} R \Big/ d_i R \right) \oplus R^f \;\; \xrightarrow{\sim} \;\; M$$

For ease of notation we let $d_i := 0$ for any $i \in (r+1) \ldots n$, such that R is isomorphic to $R/0 = R/d_iR$ and we can rewrite the isomorphism

$$\Phi \; : \; \bigoplus_{i=1}^{n} R \Big/ d_i R \;\; \xrightarrow{\sim} \;\; M$$

Let us then denote $g_1 := (1 + d_1R, 0 + d_2R, \ldots, 0 + d_nR)$ and so on, until $g_n := (0 + d_1R, \ldots, 0 + d_{n-1}R, 1 + d_nR)$. Then it is clear, that

$$R \;\; \twoheadrightarrow \;\; Rg_i \; : \; a \;\mapsto\; ag_i$$

has the kernel d_iR. But as this is the annihilator of g_i we find $\mathrm{ann}(g_i) = d_iR$. If we now let $m_i := \Phi(g_i) \in M$, then we will see, that

$$M \;\; = \;\; Rm_1 \oplus \cdots \oplus Rm_n$$

As the g_i generate M and Φ is surjective the m_i generate M. Conversely if $x \in Rm_j \cap \sum_{i \neq j} Rm_i$ then, as Φ also is injective, its preimage is contained in $\Phi^{-1}(x) \in Rg_j \cap \sum_{i \neq j} Rg_i = 0$, such that $x = 0$. But these are the two properties required for an inner direct sum.

As Φ is an isomorphism we have $\mathrm{ann}(m_i) = \mathrm{ann}(g_i) = d_iR$ and thereby the ascending chain of divisibilities $d_{i-1} \mid d_i$ turns into a descending chain of ideals $\mathrm{ann}(m_{i-1}) = d_{i-1}R \;\supseteq\; d_iR = \mathrm{ann}(m_i)$. In particular

$$\mathrm{ann}(M) \;\; = \;\; \bigcap_{i=1}^{n} \mathrm{ann}(m_i) \;\; = \;\; \mathrm{ann}(m_n)$$

Also for any $i \leq j \in 1 \ldots n$ we have $d_i \mid d_j$ and thereby $d_jm_i = 0$. For any $x = \sum_i a_im_i \in M$ this means $d_jx = \sum_i a_id_jm_i \in M$ where all summands with $i \leq j$ are deleted. Therefore we have $d_jM \subseteq Rm_{j+1} + \cdots + Rm_n$ such that we have

$$d_j \;\; \in \;\; \mathrm{ann}\left(M \Big/ Rm_{j+1} + \cdots + Rm_n \right)$$

And as the annihilator is an ideal it already contains d_jR. Conversely if $am_j + (Rm_{j+1} + \cdots + Rm_n) = 0$ then $am_j \in (Rm_j) \cap (Rm_{j+1} + \cdots + Rm_n) = 0$ such that $a \in \operatorname{ann}(m_j) = d_jR$. That is we also have

$$d_jR \;=\; \operatorname{ann}\left(M \Big/ Rm_{j+1} + \cdots + Rm_n\right)$$

(v) Let us first consider R/dR for some $d \in R$. As the PID R is a factorial ring, according to (2.79.(ii)), we find a primary decomposition

$$d \;=\; \alpha \prod_{j=1}^{s} p(j)^{m(j)}$$

of d, where $\alpha \in R^*$ and $m(j) \in \mathbb{N}$ and the $p(j) \in R$ are pairwise non-associated primes of R. In particular: If we abbreviate $a_j := p(j)^{m(j)}$ and pick up some prime $q \in R$, then $q \mid a_j$ and $q \mid a_k$ would imply $q \mid p(j)$ and $q \mid p(k)$ such that $p(j) \approx q \approx p(k)$, which is untrue. Therefore we have $1 \in \gcd\{\, a_j, a_k \,\}$ and as R is a PID we find that the ideals $\mathfrak{a}_j := a_jR$ and $\mathfrak{a}_k = a_kR$ are coprime $\mathfrak{a}_j + \mathfrak{a}_k = R$, according to the lemma of Bezout (2.83.(iii)).

But the intersection of all these ideals is dR: By definition $b \in \mathfrak{a}_j = a_jR$ is equivalent to $a_j \mid b$ such that $d \in \mathfrak{a}_j$ for any $j \in 1 \ldots s$. This is $dR \subseteq \bigcap_j \mathfrak{a}_j$. Conversely if $p(j)^{m(j)} = a_j \mid b$, then $m(j) \leq \langle p(j) \mid b \rangle$ and if this is true for any $j \in 1 \ldots s$, then $d \mid b$, such that $\bigcap_j \mathfrak{a}_j \subseteq dR$, as well. Now the Chinese remainder theorem (1.99.(iii)) yields the isomorphism

$$R \Big/ dR \;\xrightarrow{\sim}\; \bigoplus_{j=1}^{s} R \Big/ p(j)^{m(j)}R \;:\; b + dR \mapsto \left(b + p(j)^{m(j)}R\right)$$

After these preparations, let us turn to the claim at hand: If we pick up a primary decomposition of $d_r = \alpha_r\, p(1)^{m(1)} \ldots p(j)^{m(j)}$, then by assumption we have $d_i \mid d_r$ for any $i \in 1 \ldots r$. And by (2.64.(iii)) this means $\langle p(j) \mid d_i \rangle \leq \langle p(s) \mid d_i \rangle = m(j)$ which means, that we find a primary decomposition of any d_i in terms of the same prime factors

$$d_i \;=\; \alpha_i \prod_{j=1}^{s} p(j)^{m(i,j)}$$

where $m(i,j) = \langle p(j) \mid d_i \rangle$ (where we allow $m(i,j) = 0$ here). It is clear then for any $j \in 1 \ldots s$ the powers $m(1,j) \leq \cdots \leq m(r,j)$ form ascending chains. And as we have seen above, we have the isomorphies

$$R \Big/ d_iR \;\xrightarrow{\sim}\; \bigoplus_{j=1}^{s} R \Big/ p(j)^{m(i,j)}R \;:\; b + d_iR \mapsto \left(b + p(j)^{m(i,j)}R\right)$$

All we have to do is rearrange the summands in the exterior direct sum (obviously transposing the direct sum preserves the isomorphy)

$$\bigoplus_{i=1}^{r} R \Big/ d_iR \;\cong_{\mathfrak{m}}\; \bigoplus_{i=1}^{r}\bigoplus_{j=1}^{s} R \Big/ p(j)^{m(i,j)}R \;=\; \bigoplus_{j=1}^{s}\bigoplus_{i=1}^{r} R \Big/ p(j)^{m(i,j)}R$$

This almost is the representation of the claim: All we have to do is reverse the order of $m(1,j) \leq \cdots \leq m(r,j)$, by taking to the powers $n(i,j) := m(r+1-i,j)$ for $i \in 1 \ldots r$ and $j \in 1 \ldots s$. That

is the $n(i,j)$ are the same powers, but now $n(1,j) \geq \cdots \geq n(r,j)$. Note that there may still be some $n(i,j) = 0$, but in this case $p(j)^{n(i,j)} = 1$ such that $R/p(j)^{n(i,j)}R = 0$. Hence we can omit the direct summands with $n(i,j) = 0$ and define $I(j) := \max\{\, i \in 1 \ldots r \mid n(i,j) \neq 0 \,\}$. Then we arrive at the isomorphy of

$$\bigoplus_{i=1}^{r} R \Big/ d_i R \;\cong_{\mathfrak{m}}\; \bigoplus_{j=1}^{s} \bigoplus_{i=1}^{r} R \Big/ p(j)^{m(i,j)} R \;=\; \bigoplus_{j=1}^{s} \bigoplus_{i=1}^{I(j)} R \Big/ p(j)^{n(i,j)} R$$

And clearly this isomorphism can be extended by the free module R^f, such that we finally have the desired isomorphy of

$$\bigoplus_{i=1}^{r} R \Big/ d_i R \oplus R^f \;\cong_{\mathfrak{m}}\; \bigoplus_{j=1}^{s} \bigoplus_{i=1}^{I(j)} R \Big/ p(j)^{n(i,j)} R \oplus R^f$$

(iv) Consider the following R modules, where the elements $d_1, \ldots, d_r \in R$ and $e_1, \ldots, e_s \in R$ are invariant factors of a common module

$$\begin{aligned} M &:= R^f \oplus \bigoplus_{i=1}^{r} R \Big/ d_i R \\ N &:= R^g \oplus \bigoplus_{j=1}^{s} R \Big/ e_j R \end{aligned}$$

By assumption we have $M \cong_{\mathfrak{m}} N$, the base ring R is a PID and hence an UFD so that according to (5.31) this is $f = \mathrm{free}(M) = \mathrm{free}(N) = g$ and $f + r = \mathrm{rank}(M) = \mathrm{rank}(N) = g + s$. Since $f = g$ the latter implies $r = s$. But according to (3.23.(v)) we then have $\mathrm{TOR}(M) \cong_{\mathfrak{m}} \mathrm{TOR}(N)$ which now is

$$\bigoplus_{i=1}^{r} R \Big/ d_i R \;\cong_{\mathfrak{m}}\; \bigoplus_{i=1}^{r} R \Big/ e_i R$$

This isomorphy implies $e_r \in \mathrm{ann}(\mathrm{TOR}(M)) = d_r R$ and conversely $d_r \in e_r R$ such that $e_r = u_r d_r$ for some unit $u_r \in R^*$. Recall that we denote this by writing $d_r \approx e_r$. We now use induction on the length $\ell(e_i)$ of the primary decomposition of e_i, that is on the number of prime divisors of e_i (counting multiplicities).

If we start with any prime $p \in R$ and let $F := R/pR$ then F is a field, since $pR \trianglelefteq_{\mathfrak{i}} R$ is a maximal ideal of R. Also by (3.46) we have

$$M_p \;\cong_{\mathfrak{m}}\; \bigoplus_{i=1}^{r} \left(R \Big/ e_i R \right)_p \;\cong_{\mathfrak{m}}\; \bigoplus_{i=1}^{r} \begin{cases} F \text{ if } p \mid e_i \\ 0 \text{ if } p \not| e_i \end{cases}$$

Note that (3.46) also tells us, that M_p is an F-vector-space and by definition $(a + pR)m = am$ any R-linear map automatically is F-linear, too. Hence the above isomorphism of R-modules also is an isomorphism of F-vector-spaces, such that we find

$$\dim\left(M_p\right) \;=\; \#\{\, i \in 1 \ldots r \mid p \mid e_i \,\}$$

In complete analogy $\dim(M_p) = \#\{\, i \in 1\ldots r \mid p \mid e_i \,\}$. So if we start with a prime divisor of e_1 we get from $e_1 \mid e_2$ and so on until $e_{r-1} \mid e_r$ that $p \mid e_i$ for any $i \in 1\ldots r$. That is we conclude $r = \dim(M_p)$ for any prime divisor of e_1. In turn this implies $p \mid d_1$. Reversing the argument we find that e_1 and d_1 have the same prime factors (but they do not necessarily share the same multiplicities), yet we do not requires this observation for the rest of our proof.

We are now ready to present the foundation of our induction: Suppose $\ell(e_1) = 1$, i.e. $p := e_1$ is a prime itself. As $e_1 \notin R^*$ and $e_1 \mid e_2$ and so on until $e_{r-1} \mid e_r = p$ we find $e_i \approx p$ for any $i \in 1\ldots r$. As we have already argued $d_r \approx e_r = p$ such that in complete analogy we have $d_i \approx p$ for any $i \in 1\ldots r$. And in particular this implies $d_i \approx e_i$ for any $i \in 1\ldots r$.

For the induction step we start with any prime factor p of e_1, that is $p \mid e_1$ which is possible, since neither $e_1 \in R^*$ nor $e_i = 0$. Then we have $p \mid e_1 \mid e_i$ and hence $p \mid e_i$ for any $i \in 1\ldots r$ again. Let us write $e_i = p\varepsilon_i$ for some $\varepsilon_i \in R$. Now (3.46.(v)) constructs a new isomorphy

$$\textsc{tor}(M) \;\cong_{\mathsf{m}}\; \bigoplus_{i=1}^{r} R\Big/_{e_i R} \quad\Longrightarrow\quad p\,\textsc{tor}(M) \;\cong_{\mathsf{m}}\; \bigoplus_{i=1}^{r} R\Big/_{\varepsilon_i R}$$

As we have seen above, $p \mid e_1$ also implies $p \mid d_1$ and as $d_1 \mid d_2$ and so on until $d_{r-1} \mid d_r$ this is $p \mid d_i$ for any $i \in 1\ldots r$. So let us write $d_i = p\delta_i$ for some $\delta_i \in R$. Repeating the argument of (3.46.(v)) yields

$$\bigoplus_{i=1}^{r} R\Big/_{\delta_i R} \;\cong_{\mathsf{m}}\; p\,\textsc{tor}(M) \;\cong_{\mathsf{m}}\; \bigoplus_{i=1}^{r} R\Big/_{\varepsilon_i R}$$

Note that $\ell(e_r) = \ell(e_r) - 1 < \ell(e_r)$ such that the induction hypothesis implies $\varepsilon_i = u_i\delta_i$ for some $u_i \in R^*$ for any $i \in 1\ldots r$. Multiplying this by p we arrive at $e_i = u_i d_i$ which had to be shown. Thus we conclude the induction step and hence the proof.

(ii) Since M is the (inner) direct sum of the sub-modules Rp_i the p_i generate M and hence there is an epimorphism ϱ of the form

$$\varrho \;:\; R^m \twoheadrightarrow M \;:\; (a_i) \mapsto \sum_{i=1}^{m} a_i p_i$$

As R is a PID we may pick up some $d_i \in R$ such that for any $i \in 1\ldots m$ we have $\operatorname{ann}(p_i) = d_i R$. It is clear, that $d_i \notin R^*$ as we would else have $\operatorname{ann}(p_i) = R$ and hence p_i would not not occur at all and hence the sum of the Rp_i would not have been direct. Let $r := \max\{\, i \in 0\ldots m \mid d_i \neq 0 \,\}$, then we have $d_i \in R^\bullet$ for any $i \in 1\ldots r$ and $d_i = 0$ for $i \in (r+1)\ldots m$. As we have $d_i R = \operatorname{ann}(p_i) \subseteq \operatorname{ann}(p_{i-1}) = d_{i-1}R$ we also see $d_{i-1} \mid d_i$. So the d_i satisfy all the properties required for elementary divisors. We now claim that the kernel of ϱ is given to be

$$\operatorname{kn}(\varrho) \;=\; d_1R \oplus \cdots \oplus d_rR \oplus 0 \oplus \cdots \oplus 0$$

Clearly if $a = (a_i) \in R^m$ such that $a_i \in d_iR$ for any $i \in 1\ldots m$, then $a_i p_i = 0$ and hence $\varrho(a) = 0$. Conversely if $\varrho(a) = 0$ then $a_i p_i = 0$ for any $i \in 1\ldots m$, as the sum of the Rp_i has been direct. But this again means $a_i \in \operatorname{ann}(p_i) = d_i R$. Now the first isomorphism theorem of modules applied

to ϱ induces an isomorphism of the form

$$\bigoplus_{i=1}^{r} R\Big/_{d_iR} \oplus R^f \;=\; \bigoplus_{i=1}^{m} R\Big/_{d_iR} \;:\xrightarrow{\sim}\; M \;:\; \Big(a_i + d_iR\Big) \mapsto \sum_{i=1}^{m} a_i p_i$$

where $f := m - r$. The same arguments can be applied to the direct sum of M factored into Rq_j where $j \in 1 \dots n$. That is we obtain another isomorphy of the form

$$\bigoplus_{j=1}^{s} R\Big/_{e_jR} \oplus R^g \;:\xrightarrow{\sim}\; M \;:\; \Big(b_j + e_jR\Big) \mapsto \sum_{j=1}^{n} b_j q_j$$

where $e_jR = \operatorname{ann}(q_j)$ and $s := \max\big\{\, j \in 0 \dots n \mid e_j \neq 0 \,\big\}$ and $g := n - s$. In particular the direct sums of the R/d_iR and R/e_jR are isomorphic and hence we may invoke (iv) to find $r = s$ and $f = g$ and some $u_i \in R^*$ such that $e_i = u_i d_i$ for any $i \in 1 \dots r$. But this means $\operatorname{ann}(p_i) = d_iR = e_iR = \operatorname{ann}(q_i)$ for any $i \in 1 \dots r$ already. Also $m = r + f = s + g = n$ and for any $j \in (r+1) \dots n$ we have $\operatorname{ann}(p_j) = 0 = \operatorname{ann}(q_j)$. Altogether the uniqueness has been established.

(vi) Reversing the construction in (v) we let $r := \max\{\, I(j) \mid j \in 1 \dots s \,\}$ and $n(i,j) := 0$ for $I(j) < i \leq r$ and finally for any $i \in 1 \dots r$

$$d_i \;:=\; \prod_{j=1}^{s} p(j)^{n(r+1-i,j)}$$

That is we reconstruct the invariant factors from the elementary divisors. Then we have $d_i \neq 0$ (as R is an integral domain) and $d_i \notin R^*$ as at least one $n(r,j) \geq 1$ is non-zero. As $n(r,j) \leq \dots \leq n(1,j)$ we find that $d_1 \mid d_2$ and so on, until $d_{r-1} \mid d_r$. The arguments of (v) apply again, so we end up with the following isomorphy

$$\bigoplus_{i=1}^{r} R\Big/_{d_iR} \oplus R^f \quad\cong_{\mathsf{m}}\quad \bigoplus_{j=1}^{s} \bigoplus_{i=1}^{I(j)} R\Big/_{p(j)^{n(i,j)}R} \oplus R^f \quad\cong_{\mathsf{m}}\quad M$$

Likewise we take $q := \max\{\, K(\ell) \mid \ell \in 1 \dots t \,\}$ and define e_k to be the product of the $q(\ell)^{m(q+1-k,\ell}$ where ℓ rund from 1 to t. Then we get the second isomorphy

$$\bigoplus_{k=1}^{q} R\Big/_{e_kR} \oplus R^g \quad\cong_{\mathsf{m}}\quad M$$

As both are isomorphic to M we can invoke (iv) to see that $r = q$, $f = g$ and $e_i = u_i d_i$ for some $u_i \in R^*$ for any $i \in 1 \dots r$. Explicitly that is (for any $i \in 1 \dots r$)

$$\prod_{\ell=1}^{t} q(\ell)^{m(r+1-i,\ell)} \;=\; u_i \prod_{j=1}^{s} p(j)^{n(r+1-i,j)}$$

That is we have found two prime decompositions of e_i, but these are essentially unique, that is we may apply (2.58.(viii)). Applying this to $i = r$ this theorem tells us that any $p(j)$ is the associate of some $q(\ell)$. As the $p(j)$ (likewise the $q(\ell)$ are pairwise non-associated the s distinct primes $q(j)$ correspond to the $t = s$ distinct primes $q(\ell)$. I.e. there is a permutation σ of $1 \dots s$ such that $p(j) \approx q(\sigma(j))$. And if $q(j)$ appears $n(r+1-i,j)$-times in d_i then $q(\sigma(j))$ appears just as often

in e_i (this includes the cases where d_i does not appear at all, i.e. when $n(r+1-i,j)=0$). That is we have $m(r+1-i,\sigma(j))=n(r+1-i,j)$ for any $i \in 1\dots r$ and any $j \in 1\dots s$. Reversing the order by going to $h=r+1-i$ we have $m(h,\sigma(j))=n(h,j)$ for any $h \in 1\dots r$, as claimed. And as the minimum $h \in 1\dots r$ such that $n(h,j)=0$ is the same for $m(h,\sigma(j))$ we see $I(j)=K(\sigma(j))$. That is all the uniqueness properties of the claim are satisfied.

□

15.7 Proofs of Chapter 6

Proof of (6.3):
First of all, it is clear that $\sim$ truly is an equivalence relation: As $d(x,x) = 0$ we have the reflexivity $x \sim x$. And if $x \sim y$ then $d(y,x) = d(x,y) = 0$ by (M3), such that $y \sim x$ again, this is the symmetry of the relation. And if $x \sim y$ and $y \sim z$, then by (M1) and (M4) we have

$$0 \;\leq\; d(x,z) \;\leq\; d(x,y) + d(y,z) \;=\; 0 + 0 \;=\; 0$$

such that we get $x \sim z$ from $d(x,z) = 0$, which is the transitivity of the relation. Let us prove the well-definedness of $D([x],[y]) := d(x,y)$ next: That is we consider any $u \in [x]$ and $v \in [y]$ and need to show $d(u,v) = d(x,y)$. By assumption $u \in [u]$ we have $u \sim x$ such that $d(u,x) = 0$, likewise $v \sim y$, such that $d(v,y) = 0$. Then we get

$$d(u,v) \;\leq\; d(u,x) + d(x,v) \;=\; d(x,v) \;\leq\; d(x,y) + d(y,v) \;=\; d(x,y)$$

That is $d(u,v) \leq d(x,y)$ and in complete analogy we find $d(x,y) \leq d(u,v)$. Hence $d(u,v) = d(x,y)$ are equal and thereby D is well-defined. It remains to prove that D is a metric: (M1) $D([x],[y]) = d(x,y) \geq 0$ and (M3) $D([x],[y]) = d(x,y) = d(y,x) = D([y],[x])$ are obvious. The triangle inequality of D is also inherited from d, as $D([x],[z]) = d(x,z) \leq d(x,y) + d(y,z) = D([x],[y]) + D([y],[z])$. So for (M2) finally: If $D([x],[y]) = 0$, then $d(x,y) = 0$ such that $x \sim y$, which means $[x] = [y]$, altogether D is a metric. □

Proof of (6.4):

(i) Let $\delta := d(x,y)$, as $y \in B_r(x)$ we have $\delta < r$ by definition of the open balls. Now let $\varepsilon := (r-\delta)/2$, then we have $0 < \varepsilon \leq r/2 < r$ again. We now claim that $B_\varepsilon(y) \subseteq B_r(x)$. That is we consider any $z \in B_\varepsilon(y)$, which means $d(y,z) < \varepsilon$. Then we compute

$$d(x,z) \;\leq\; d(x,y) + d(y,z) \;<\; \delta + \varepsilon \;=\; \delta + \frac{r-\delta}{2} \;=\; \frac{r+\delta}{2} \;>\; r$$

In particular $z \in B_r(x)$ and as this is true for any $z \in B_\varepsilon(y)$ we have $B_\varepsilon(y)$. In particular for $P = B_r(x)$ we get: If $y \in P$, then $B_\varepsilon(y) \subseteq P$, which makes P an open subset of X.

(ii) As $x \neq y$ we have $r := d(x,y) > 0$. Now let $\varepsilon := r/3$ and define $U := B_\varepsilon(x)$ and $V := B_\varepsilon(y)$. Then $x \in U$ and $y \in V$ are obvious. Also U and V are open subsets of X, by (i). It remains to prove $U \cap V = \emptyset$. Thus assume $z \in U \cap V$, then from $z \in U = B_\varepsilon(x)$ we would get $d(x,z) < \varepsilon$ and likewise $d(y,z) < \varepsilon$ from $z \in V = B_\varepsilon(y)$. But then we had $d(x,y) < r$, in contradiction, to $d(x,y) = r$, as we would be able to compute

$$d(x,y) \;\leq\; d(x,z) + d(z,y) \;<\; \varepsilon + \varepsilon \;=\; \frac{2}{3}r \;<\; r$$

(iii) The "open" part of property (1) has been proved in (i). And $x \in B_r(x)$ is true for any $r > 0$, as $d(x,x) = 0 < r$. Property (2) is obvious, as $y \in F_{n+1}(x)$ means $d(x,y) < 1/(n+1) < 1/n$ which implies $y \in F_n(x)$. For (3) we consider some $y \in X$ such that $y \in F_n(x)$ for any $n \in \mathbb{N}$. Let $r := d(x,y)$ then $y \in F_n(x)$ means $r < 1/n$. And as this is true for any $n \in \mathbb{N}$ this can

only be $r = 0$. But as d is a metric, this means $y = x$ again. Finally (4) is immediate from the definition of open sets: If $U \subseteq X$ is open and $x \in U$, then by definition we have $B_r(x) \subseteq U$ for some $r > 0$. Now simply take $n \in \mathbb{N}$ such that $1/n \leq r$, then $F_n(x) = B_{1/n}(x) \subseteq B_r(x) \subseteq U$. Property (5) is a slight refinement of (ii): Given $x \neq y \in X$ let $r := d(x,y)$ and choose $n \in \mathbb{N}$ such that $1/n \leq \varepsilon := r/3$. Then we get $F_n(x) \subseteq B_\varepsilon(x)$ and $F_n(y) \subseteq B_\varepsilon(y)$. And thereby $F_n(x) \cap F_n(y) \subseteq B_\varepsilon(x) \cap B_\varepsilon(y) = \emptyset$, as we have seen in (ii). In particular $F_n(x) \cap F_n(y) = \emptyset$.

In property (6) we have $F_0(x) = X$ for any $x \in X$, by definition. So we only have to deal with the second part of (6): That is we consider some $F, G \in \mathcal{F}$, say $F = F_m(y)$ and $G = F_n(z)$ and an element $x \in F \cap G$. Recall that $F = B_{1/m}(y)$ and $G = B_{1/n}(z)$ and let $\varepsilon(y) := (1/m - d(x,y))/2$ and $\varepsilon(z) := (1/n - d(x,z))/2$. Note that $\varepsilon(y)$ and $\varepsilon(z) > 0$, as $x \in F$ and $x \in G$ respectively. Also may choose some $k \in \mathbb{N}$ such that $1/k \leq \min\{\, \varepsilon(y), \varepsilon(z) \,\}$, then by (i) we have $B_{1/k}(x) \subseteq B_{\varepsilon(y)}(x) \subseteq B_{1/m}(y) = F$ and analogously $B_{1/k}(x) \subseteq B_{\varepsilon(z)}(x) \subseteq B_{1/n}(z) = G$. Thus if we take $E := B_{1/k}(x)$, then we have $x \in E = F_k(x)$ and $E \subseteq F \cap G$, as required.

□

Proof of (6.6):

- We start with (a) $\implies$ (b): That is we are given $x \in X$ and $\varepsilon > 0$ and need to find a sufficient $\delta > 0$. Abbreviate $V := B_\varepsilon(Y, f(x))$, which is an open set in Y. By assumption (a) we know that $U := f^{-1}(V) = \{\, y \in X \mid f(y) \in V \,\}$ is an open set of X. Also $x \in U$, as $f(x) \in V$. By the definition of open sets, this means $B_\delta(X,x) \subseteq U$ for some $\delta > 0$. Thus for any $y \in B_\delta(X,x)$ we have $y \in U = f^{-1}(V)$ such that $f(y) \in V = B_\varepsilon(Y, f(x))$, which is (b) precisely.

- Conversely, for (b) $\implies$ (a): We begin with an open set $V \subseteq Y$ and let $U := f^{-1}(V)$. We need to show, that $U \subseteq X$ is open, that is for any $x \in U$ there has to be some $r > 0$ such that $B_r(x) \subseteq U$. As $x \in U$ we have $f(x) \in V$ and as $V \subseteq Y$ is open, this means $B_\varepsilon(Y, f(x)) \subseteq V$ for some $\varepsilon > 0$. Choose $\delta > 0$ such that $y \in B_\delta(X,x)$ implies $f(y) \in B_\varepsilon(Y, f(x)) \subseteq V$. Then $f(y) \in V$ means $y \in f^{-1}(V) = U$. And as this is true for any $y \in B_\delta(X,x)$ we have $B_\delta(X,x) \subseteq U$. Thus (by taking $r := \delta$) we proved, that $U = f^{-1}(V)$ is an open subset of X, again.

- Now to (b) $\implies$ (c): That is we are given a converging sequence $(x_n) \to x$ and need to show $(f(x_n)) \to f(x)$. The latter is: Given any $\varepsilon > 0$ there is some $n(\varepsilon) \in \mathbb{N}$ such that for any $n \geq n(\varepsilon)$ we have $f(x_n) \in B_\varepsilon(Y, f(x))$. By assumption (b) there is some $\delta > 0$ such that for any $y \in B_\delta(X,x)$ we have $f(y) \in B_\varepsilon(Y, f(x))$. Also $(x_n) \to x$, which means, that there is some $n(\delta) \in \mathbb{N}$ such that for any $n \geq n(\delta)$ we have $x_n \in B_\delta(X,x)$. Thus for $y = x_n$ for some $n \geq n(\delta)$ we get $x_n \in B_\delta(X,x)$ and hence $f(x_n) \in B_\varepsilon(Y, f(x))$. So by taking $n(\varepsilon) := n(\delta)$ we are done.

- It remains to verify (c) $\implies$ (b): Here we start with some $x \in X$ and $\varepsilon > 0$ again and need to find a sufficient $\delta > 0$. Assume this was false - there is no such δ. This means that for any $\delta > 0$ there is some $y \in B_\delta(X,x)$ such that $f(y) \notin B_\varepsilon(Y, f(x))$. For any $n \in \mathbb{N}$ take $\delta := 1/(n+1)$ then there is some $x_n \in B_\delta(X,x)$ such that $f(x_n) \notin B_\varepsilon(Y, f(x))$. Let us verify, that for this sequence we have $(x_n) \to x$: Given $r > 0$ take $n(r) \in \mathbb{N}$ in such a way, that $1/n(r) \leq r$. Then for any $n \geq n(r)$ we get $1/n \leq 1/n(r) \leq r$. For x_n we have $d(x, x_n) < 1/(n+1) < 1/n \leq \varepsilon$, by construction. Thus $x_n \in B_r(X,x)$ for any $n \geq n(r)$, which is the definition of $(x_n) \to x$. Thus by assumption (c) we have $(f(x_n)) \to f(x)$, too. Yet by construction we have $f(x_n) \notin B_\varepsilon(Y, f(x))$ for any $n \in \mathbb{N}$. In

particular $f(x_n) \to f(x)$ is impossible. This contradiction can only be solved, if there was some $\delta > 0$ with the desired property, to begin with.

□

Proof of (6.8):

(i) Consider any $y \in B_{r/M}(D,x)$, that is $D(x,y) < r/M$. By assumption we have the following estimate: $d(x,y) \leq M \cdot D(x,y) < r$ and thereby $y \in B_r(d,x)$. As this is true for any y we have the inclusion $B_{r/M}(D,x) \subseteq B_r(d,x)$.

(ii) As $d \leq D$ there is some $M > 0$ such that the assumption in (i) is always satisfied. Now consider any $U \subseteq \mathcal{T}_d$, that is for any $x \in U$ there is some $r > 0$ such that $B_r(d,x) \subseteq U$. But then we have seen in (i), that $B_{r/M}(D,x) \subseteq B_r(d,x) \subseteq U$. As $r/M > 0$, still this means that $U \in \mathcal{T}_D$ and as this is true for any U we have the inclusion $\mathcal{T}_d \subseteq \mathcal{T}_D$.

(iii) We have to prove $(x_n) \to_d x$ which means that for any $\varepsilon > 0$ there has to be some $n(\varepsilon) \in \mathbb{N}$, such that for any $n \geq n(\varepsilon)$ we find $x_n \in B_\varepsilon(d,x)$. But as $(x_n) \to_D x$ and $\varepsilon/M > 0$, still there is some $n(\varepsilon) \in \mathbb{N}$ such that for any $n \geq n(\varepsilon)$ we have $x_n \in B_{\varepsilon/M}(D,x)$. Now by (i) we have $B_{\varepsilon/M}(D,x) \subseteq B_\varepsilon(d,x)$, such that $x_n \in B_\varepsilon(d,x)$ is true. Thus we have found $(x_n) \to_d x$, as well.

□

Proof of (6.16):

(i) Let us denote $\mathcal{U}(P) := \{\, U \subseteq X \text{ open} \mid U \subseteq P \,\}$, then P° has been defined, as the grand union $P^\circ = \bigcup \mathcal{U}(P)$. Note that $\emptyset$ is open and hence $\emptyset \in \mathcal{U}(P)$. But by definition of a topology any union of open sets is open, in particular $P^\circ = \bigcup \mathcal{U}(P)$ is open. It remains to verify

$$P^\circ \;=\; \{\, x \in P \mid \exists\, U \subseteq X \text{ open} : x \in U \subseteq P \,\}$$

If $x \in P$ admits some U with $x \in U \subseteq P$, then $U \in \mathcal{U}(P)$ and hence $U \subseteq P^\circ$ such that $x \in P^\circ$. Conversely if $x \in P^\circ$, then there is some $U \in \mathcal{U}(P)$ with $x \in U$. But then $x \in U \subseteq P$ makes x an element of the right-hand set.

(ii) Let us denote $\mathcal{Z}(P) := \{\, C \subseteq X \text{ closed} \mid P \subseteq C \,\}$, then $\overline{P}$ has been defined, as the intersection $\overline{P} = \bigcap \mathcal{Z}(P)$. Note that X is closed and hence $X \in \mathcal{Z}(P)$, such that the intersection is well-defined (it runs over a non-empty set). By (6.10) any non-empty intersection of closed sets is closed again, in particular $\overline{P} = \bigcap \mathcal{Z}(P)$ is closed. It remains to verify $\overline{P} = X \setminus Q^\circ$ for $Q := X \setminus P$. But this is a simple consequence of complements: Let $C := X \setminus U$, which is a closed set of X, then

$$\begin{aligned}
X \setminus Q^\circ &= X \setminus \bigcup \{\, U \mid U \subseteq X \text{ open}, U \subseteq Q \,\} \\
&= \bigcap \{\, X \setminus U \mid U \subseteq X \text{ open}, U \subseteq Q \,\} \\
&= \bigcap \{\, C \mid C \subseteq X \text{ closed}, X \setminus C \subseteq Q \,\} \\
&= \bigcap \{\, C \mid C \subseteq X \text{ closed}, C \supseteq X \setminus Q \,\} \\
&= \bigcap \{\, C \mid C \subseteq X \text{ closed}, C \supseteq P \,\} \;=\; \overline{P}
\end{aligned}$$

(iii) Just note that $\partial P = \overline{P} \setminus P^\circ$ can also be written, as $\partial P = \overline{\mathcal{P}} \cap (X \setminus P^\circ)$ and this is an intersection of closed sets, by (ii) and (i) respectively, and thereby this is a closed set again.

(vi) By construction any $U \in \mathcal{U}(P)$ is contained in $U \subseteq P$. Thus if we consider any $x \in P^\circ = \bigcup \mathcal{U}(P)$, then $x \in U$ for some $U \in \mathcal{U}(P)$ and as $U \subseteq P$ this yields $x \in P$. Therefore we have $P^\circ \subseteq P$. Likewise for any $C \in \mathcal{Z}(P)$ we have $P \subseteq C$. So if we start with any $x \in P$, then $x \in C$ for any $C \in \mathcal{Z}(P)$. But this means $x \in \bigcap \mathcal{Z}(P) = \overline{P}$, such that we get the inclusion $P \subseteq \overline{P}$, as well.

(iv) By (i) U° is open, thus if $U = U^\circ$ then U already is open. Conversely, if U is open, then $U \in \mathcal{U}(U)$ and therefore $U \subseteq \bigcup \mathcal{U}(U) = U^\circ$. But $U^\circ \subseteq U$ is generally true, by (vi) and therefore $U = U^\circ$.

(v) By (ii) $\overline{C}$ is closed, thus if $C = \overline{C}$, then C already is closed. Conversely, if C is closed, then $C \in \mathcal{Z}(C)$ and therefore $\overline{C} = \bigcap \mathcal{Z}(C) \subseteq C$. But $C \subseteq \overline{C}$ is generally true and therefore $C = \overline{C}$.

(vii) By definition we have $\partial P = \overline{P} \setminus P^\circ$. Taking the union with P° on both sides, we alredy get the claim $\partial P \cup P^\circ = (\overline{P} \setminus P^\circ) \cup P^\circ = \overline{P}$ already.

(viii) Let us denote $\mathcal{Z}(P) := \{ Z \subseteq X \text{ closed} \mid P \subseteq Z \}$, then $C \in \mathcal{Z}(P)$ by assumption. And by definition we have $\overline{P} = \bigcap \mathcal{Z}(P)$, but $\bigcap \mathcal{Z}(P) \subseteq C$, as C is part of this grand intersection.

(ix) By (i) we have $V^\circ = \{ x \in V \mid \exists U \in \mathcal{T}(x) : U \subseteq V \}$. And by assumption we have $x \in V^\circ$ for any $x \in V$. This is $V \subseteq V^\circ$ and as $V^\circ \subseteq V$ is generally true by (vi), we get $V = V^\circ$. But by (iv) this means that V is open.

(x) By definition the closure of P in S is the intersection of all closed subsets in S that contain P. And by construction of the relative topology a subset $C \subseteq S$ is closed, iff it is of the form $C = D \cap S$ for some closed subset $D \subseteq X$. Therefore we have

$$\mathrm{cl}_S(P) \;=\; \bigcap \{ C \subseteq S \text{ closed} \mid P \subseteq C \} \;=\; \bigcap \{ D \cap S \mid D \subseteq X \text{ closed}, P \subseteq D \cap S \}$$

As $P \subseteq S$ is given $P \subseteq D \cap S$ is equivalent to $P \subseteq D$. Also we can pull out $\cap S$ from the grand intersection, as it always is the same set. But doing this we see, that the expression left is just the closure of P as a subset of X and thereby

$$\overline{P} \;=\; \bigcap \{ D \mid D \subseteq X \text{ closed}, P \subseteq D \} \cap S \;=\; \mathrm{cl}_X(P) \cap S$$

□

Proof of (6.12):

(i) Clearly $\emptyset = \emptyset \cap S$ and as $S \subseteq X$ also $S = X \cap S$, such that properties (T1) and (T2) are satisfied for $\mathcal{T} \cap S$. Also if $U \cap S$ and $V \cap S \in \mathcal{T} \cap S$, then $(U \cap S) \cap (V \cap S) = (U \cap V) \cap S$ and as $U \cap V \in \mathcal{T}$ again this is property (T3). Likewise for any $\{ U_i \cap S \mid i \in I \}$ where $U_i \in \mathcal{T}$ for any $i \in I$ it is clear that $\bigcup_i (U_i \cap S) = (\bigcup_i U_i) \cap S$ and by assumption we have $\bigcup_i U_i \in \mathcal{T}$ again. That is $\bigcup_i (U_i \cap S) \in \mathcal{T} \cap S$ and this has been property (T4) of the topology $\mathcal{T} \cap S$.

(ii) (T1) is due to (C2): $\emptyset = X \setminus X \in \mathcal{T}$ and (T2) is due to (C1): $X = X \setminus \emptyset \in \mathcal{T}$. (T3) is due to (C3) by going to complements: If $U = X \setminus C$ and $V = X \setminus D$ then $U \cap V = (X \setminus C) \cap (X \setminus D) = X \setminus (C \cup D)$

where we have $C \cup D \in \mathcal{Z}$, such that $U \cap V \in \mathcal{T}$ again. Likewise (T4) is due to (C4) by going to complements: Consider any $\mathcal{U} = \{ U_i \mid i \in I \}$ where $U_i = X \setminus C_i$ for some $C_i \in \mathcal{Z}$, by assumption. Then $\bigcup_i U_i = \bigcup (X \setminus C_i) = X \setminus (\bigcap_i C_i)$ and as $\bigcap_i C_i \in \mathcal{Z}$ again, this implies $\bigcup_i U_i \in \mathcal{T}$.

(iii) Let us prove prove that $\mathcal{T} := \{ U \subseteq X \mid \text{(a)} \}$ is a topology on X: Property (T1) is trivial: As $\emptyset$ does not contain any elements, there is nothing to prove. (T2) is "X is an open set": But by (B1) any $x \in X = \bigcup \mathcal{B}$ is contained in some $B \in \mathcal{B}$. And $B \subseteq X$ is trivial, such that we have $x \in B \subseteq X$, as required. Now for (T3) we are given two open sets $U, V \in X$ and need to show, that $U \cap V$ is open again. Hence we consider any $x \in U \cap V$: As $x \in U$ there is some $B \in \mathcal{B}$ with $x \in B \subseteq U$, likewise there is some $C \in \mathcal{B}$ with $x \in C \subseteq V$. In particular $x \in B \cap C$. Now by (B2) there is some $A \subseteq \mathcal{B}$ such that $x \in A \subseteq B \cap C$. As $B \subseteq U$ and $C \subseteq V$ we have $B \cap B \subseteq U \cap V$ and thereby $x \in A \subseteq U \cap V$, as required for an open set. Finally for (T4) we are given a collection $\mathcal{U} = \{ U_i \mid i \in I \}$ of open sets in X and need to prove that it satisfies (a) again: Consider some $x \in \bigcup_i U_i$. That is $x \in U_j$ for some $j \in I$. And as U_j is open this means that there is some $B \in \mathcal{B}$ such that $x \in B \subseteq U_j$. In particular $U_j \subseteq \bigcup_i U_i$ and hence $x \in B \subseteq \bigcup_i U_i$.

(iii) In the second step, let us verify, that for any subset $U \subseteq X$ the properties (a) and (b) are equivalent: We begin with (b) $\implies$ (a): Given any $x \in U = \bigcup_i B_i$ there is some $j \in I$ with $x \in B_j$. On the other hand we have $B_j \subseteq \bigcup_i B_i = U$ such that $x \in B_j \subseteq U$ for some $B_j \in \mathcal{B}$. Conversely (a) $\implies$ (b): That is for any $x \in U$ there is some base set $B_x \in \mathcal{B}$ with $x \in B_x$ and $B_x \subseteq \mathcal{B}$. Let us take $I := U$, then we claim that $\{ B_x \mid x \in U \}$ satisfies $U = \bigcup_x B_x$. For any $x \in U$ we have $x \in B_x$ such that $U \subseteq \bigcup_x B_x$. Conversely if $y \in \bigcup_x B_x$ then there is some $x \in U$ such that $y \in B_x$. But as $B_x \subseteq U$ this yields $y \in U$ such that $\bigcup_x B_x \subseteq U$, as well.

(iv) Recall that for any $U \subseteq X$ we have $U \in \mathcal{T}$ if and only if $U \in \mathcal{T}_i$ for any $i \in I$. (T1) As $\emptyset \in \mathcal{T}_i$ for any $i \in I$ we have $\emptyset \in \mathcal{T}$ again. (T2) The same $X \in \mathcal{T}$ is true, as $X \in \mathcal{T}_i$ for any $i \in I$, too. (T3) Consider $U, V \in \mathcal{T}$, that is $U, V \in \mathcal{T}_i$ for any $i \in I$. As $\mathcal{T}_i$ is a topology we have $U \cap V \in \mathcal{T}_i$ again. And as this is true for any $i \in I$, we conclude $U \cap V \in \mathcal{T}$. (T4) We are given some $\mathcal{U} \subseteq \mathcal{T}$, that is any $U \in \mathcal{U}$ is contained in $U \in \mathcal{T}$ and thereby $U \in \mathcal{T}_i$ for any $i \in I$. As this is true for any $U \in \mathcal{U}$ we have $\mathcal{U} \subseteq \mathcal{T}_i$ again. Now $\mathcal{T}_i$ is a topology and hence $\bigcup \mathcal{U} \in \mathcal{T}_i$. And as this is true for any $i \in I$ we conclude $\bigcup \mathcal{U} \in \mathcal{T}$.

(v) (T1) is clear, as $\emptyset = f^{-1}(\emptyset)$ and likewise (T2) is satisfied, because of $X = f^{-1}(Y)$. (T3) consider $U_1, U_2 \in f^{-1}(\mathcal{T}_Y)$, that is $U_i = f^{-1}(V_i)$ for some $V_i \subseteq Y$ open. Then by (0.7) we have $f^{-1}(V_1 \cap V_2) = f^{-1}(V_1) \cap f^{-1}(V_2) = U_1 \cap U_2$ and as $V_1 \cap V_2 \in \mathcal{T}_Y$ this means $U_1 \cap U_2 \in f^{-1}(\mathcal{T}_Y)$ again. (T4) consider $\mathcal{U} = \{ U_i \mid i \in I \} \subseteq f^{-1}(\mathcal{T}_Y)$ that is any $U_i \in \mathcal{U}$ is of the form $U_i = f^{-1}(V_i)$ for some $V_i \in \mathcal{T}_Y$. Then by (0.7) we also have $f^{-1}(\bigcup_i V_i) = \bigcup_i f^{-1}(V_i) = \bigcup_i U_i$ and as $\bigcup_i V_i \in \mathcal{T}_Y$ this means $\bigcup_i U_i \in f^{-1}(\mathcal{T}_Y)$, as well.

(vi) Let us abbreviate the cartesian product by $X := \prod_i X_i$ and the following subset $\mathcal{B}$ of $\mathcal{P}(X)$. We will prove that $\mathcal{B}$ is the basis of a topology on X, where

$$\mathcal{B} \;:=\; \left\{ \prod_{i \in I} U_i \;\middle|\; \forall\, i \in I \,:\, U_i \subseteq X_i \text{ open} \right\}$$

Property (B1) is clear, as we even have $X = \prod_i X_i \in \mathcal{B}$. Now consider $B = \prod_i U_i$ and $C =$

$\prod_i V_i \in \mathcal{B}$, such that $(x_i) \in B \cap C$. That is $x_i \in U_i \cap V_i$ and $U_i \cap V_i \in \mathcal{T}_i$ again. Thus we can define $A := \prod_i (U_i \cap V_i) \in \mathcal{B}$ and thereby have $(x_i) \in A$ and $A \subseteq B \cap C$. That is $\mathcal{B}$ satisfies (B1) and (B2) in (iii) and thereby $\prod_i \mathcal{T}_i$ is a topology on X.

□

Proof of (6.18):

(i) Let $C \subseteq \bigcup_i U_i$ (where $i \in I$) be an open cover of C. As C is closed, $V := X \setminus C$ is open and hence we find an open cover of X, by adding V to the cover of C:

$$X \;=\; C \cup (X \setminus C) \;=\; \bigcup_{i \in I} U_i \cup V$$

As X is compact there is a finite subset $\Omega \subseteq I$ such that $X = \bigcup_i U_i \cap V$ where i runs in $i \in \Omega$. But as $V \cap V = \emptyset$, intersecting this identity with C we find, that these U_i already cover C

$$C \;=\; X \cap C \;=\; \bigcup_{i \in \Omega} U_i \cap C \;\subseteq\; \bigcup_{i \in \Omega} U_i$$

(ii) Let $K := K_1 \cup \cdots \cup K_n$ be the union of these sets and consider an open cover $K \subseteq \bigcup_i U_i$ (where i runs in some set $i \in I$). For any $j \in 1 \ldots n$ we have $K_j \subseteq K \subseteq \bigcup_i U_i$ such that the compactness of K_j yields a finite subset $\Omega(j) \subseteq I$ such that $K_j \subseteq \bigcup_i U_i$ where this i runs in $i \in \Omega(j)$. Now let $\Omega := \Omega(1) \cup \cdots \cup \Omega(n) \subseteq I$, which again is a finite set. Then we find a finite subcover of K, by

$$K \;=\; \bigcup_{j=1}^{n} K_j \;\subseteq\; \bigcup_{j=1}^{n} \bigcup_{i \in \Omega(j)} U_i \;=\; \bigcup_{i \in \Omega} U_i$$

□

Proof of (6.21):

(i) The implication (a) $\Longrightarrow$ (b) is trivial: This is property (F3) of a system of local filters. Conversely for (b) $\Longrightarrow$ (a) we start with an arbitrary subset $U \subseteq X$ satisfying (b). That is for any $x \in U$ there is some index $n \in \mathbb{N}$ such that $F_n(x) \subseteq U$. Thereby we may take $n(x) \in \mathbb{N}$ to be the minimal index, such that $U_x := F_{n(x)}(x) \subseteq U$. By (F1) $U_x \subseteq X$ is an open subset, with $x \in U_x$ and. And as $U_x \subseteq U$ by construction, it is clear that

$$U \;=\; \bigcap_{x \in U} U_x$$

That is: U is the union of a collection of open subsets $U_x \subseteq X$. And by property (T4) of a topology, this union is open again. And as the union equals U, this means $U \subseteq X$ is open.

(ii) If $\mathcal{F}$ is a system of local filters, then $(X, \mathcal{T})$ is a Hausdorff-space: Consider any two $x \neq y$ then by (F4) there is some $n \in \mathbb{N}$, such that $F_n(x) \cap F_n(y) = \emptyset$. But by (F1) $F_n(x) \in \mathcal{T}(x)$ and $F_n(y) \in \mathcal{T}(y)$ these are open sets, containing x and y respectively. Also $\mathcal{F}$ already is a countable filter base of $(X, \mathcal{T})$: By assumption (F1) we have $F_n(x) \in \mathcal{T}(x)$ and $\mathcal{F}(x) = \{\, F_n(x) \mid n \in \mathbb{N} \,\}$ is

countable by construction. Also, we have already shown that any $U \in \mathcal{T}(x)$ contains some $F_n(x)$ in the implication (a) $\implies$ (b) of (i).

Conversely suppose (1) and (2), then we have to construct a system of local filters of X: By assumption $\mathcal{B}(x)$ is countable, so let us do this $\mathcal{B}(x) = \{ B_n(x) \mid n \in \mathbb{N} \}$ in any order, whatsoever. Then we define

$$F_n(x) \;:=\; \bigcap_{k=0}^{n} B_k(x)$$

As $\mathcal{B}(x) \subseteq \mathcal{T}(x)$ we have $x \in F_n(x)$ again. And as $F_n(x)$ is a *finite* intersection of open sets, it is open, too. That is for any $n \in \mathbb{N}$ we have $F_n(x) \in \mathcal{T}(x)$ again, which is (F1). The $F_n(x)$ form a descending chain by construction, so (F2) is satisfied, as well. Now, if $U \in \mathcal{T}(x)$, then there is some $B \in \mathcal{B}(x)$, such that $B \subseteq U$. Say $B = B_n(x)$, then $F_n(x) \subseteq B_n(x) = B \subseteq U$, which is property (F3). Finally for (F4): Given $x \neq y \in X$ there are some open sets $U, V \subseteq X$, such that $x \in U$, $y \in V$ and $U \cap V = \emptyset$, due to (1). That is $U \in \mathcal{T}(x)$ and $V \in \mathcal{T}(y)$. As we just argued, there is some $r \in \mathbb{N}$, such that $F_r(x) \subseteq U$ and likewise $F_s(y) \subseteq V$ for some $s \in \mathbb{N}$. Now let $n := \max\{ r, s \}$, then $F_n(x) \subseteq F_r(x) \subseteq U$ and $F_n(y) \subseteq F_s(y) \subseteq V$. In particular $F_n(x) \cap F_n(y) \subseteq U \cap V = \emptyset$, such that $F_n(x) \cap F_n(y) = \emptyset$.

(iii) (1) If $(x_n) \subseteq X$ is a sequence for which there is some $N \in \mathbb{N}$, such that for any $n \geq N$ we have $x_n = x$, then for any $m \in \mathbb{N}$ we can take $n(m) := m$, as for this we get $x_n = x \in F_m(x)$ for any $n \geq N = n(m)$. (2) Suppose $(x_n) \to_{\mathcal{F}} x$ and $(x_n) \to_{\mathcal{F}} y$ for some $x, y \in X$. That is for any $m \in \mathbb{N}$ there were some $r(m), s(m) \in \mathbb{N}$ such that $x_n \in F_m(x)$ for any $n \geq r(m)$ respectively $x_n \in F_m(y)$ for any $n \geq s(m)$. Let $n(m) := \max\{ r(m), s(m) \}$, then for any $n \geq n(m)$ we had $x_n \in F_m(x) \cap F_m(y)$. That is for any $m \in \mathbb{N}$ we have $F_m(x) \cap F_m(y) \neq \emptyset$ and by property (F4) this can only happen, in case $x = y$.

(iv) By the symmetry of the situation it suffices to prove one implication of the equivalence. So let us assume $(x_n) \to_{\mathcal{F}} x$ and we would like to show $(x_n) \to_{\mathcal{E}} x$. That is for any $m \in \mathbb{N}$ we need to find some $n(m) \in \mathbb{N}$ such that for any $n \geq n(m)$ we get $x_n \in E_m(x)$. But $E_m(x) \in \mathcal{T}(x)$ such that by (F3) of $\mathcal{F}$ there is some $r(m) \in \mathbb{N}$ such that $F_{r(m)}(x) \subseteq E_m(x)$. Also we have $(x_n) \to_{\mathcal{F}} x$ such that there is some $s(r(m)) \in \mathbb{N}$ such that for any $n \geq s(r(m))$ we have $x_n \in F_{r(m)}(x)$. Now let $n(m) := s(r(m))$, then for any $n \geq n(m)$ we have $x_n \in F_{r(m)}(x) \subseteq E_m(x)$. And thereby we have established $(x_n) \to_{\mathcal{E}} x$.

(v) For the inclusion from right to left we start with a sequence $(x_n) \subseteq P$ that converges $(x_n) \to_{\mathcal{F}} x$ for some $x \in X$ and need to show $x \in \overline{P}$. Suppose this was false, i.e. $x \notin \overline{P}$. That is $x \in U := X \setminus \overline{P}$, which is an open set in X. By (6.16.(vi)) we have $P \subseteq \overline{P}$ and therefore $U = X \setminus \overline{P} \subseteq Q := X \setminus P$. By (6.15) we even have $\overline{P} = X \setminus Q^\circ$ which is $U = Q^\circ$. We have assumed $x \in U$, that is $x \in Q^\circ$ and need to find a contradiction. Thus take a look at the interior of Q, by (6.15) again, this is

$$Q^\circ \;=\; \{ x \in Q \mid \exists\, V \subseteq X \text{ open} : x \in V \subseteq Q \}$$

As $x \in Q^\circ$ there is some $V \subseteq X$ open, such that $x \in V$ and $V \subseteq Q = X \setminus P$. As $V \in \mathcal{T}(x)$ and $\mathcal{F}$ is a system of local filters there is some $m \in \mathbb{N}$, such that $F_m(x) \subseteq V$. Recall that we also have $(x_n) \to_{\mathcal{F}} x$, that is for any $m \in \mathbb{N}$ there is some $n(m) \in \mathbb{N}$ such that for any $n \geq n(m)$ we have

$x_n \in F_m(x)$. In particular $x_{n(m)} \in F_m(x) \subseteq V \subseteq Q = X \setminus P$. But this contradicts $(x_n) \subseteq P$, as this would imply $x_{n(m)} \in P$. Thus the assumption $x \notin \overline{P}$ cannot be and hence $x \in \overline{P}$.

(v) For the inclusion from left to right we start with some $x \in \overline{P}$ and need to find a sequence $(x_n) \subseteq P$ such that $(x_n) \to_{\mathcal{F}} x$. By (6.15) again, we have $\overline{P} = X \setminus Q^\circ$ where $Q := X \setminus P$. As $x \in \overline{P}$ we have $x \notin Q^\circ$ and this means:

$$\forall\, V \subseteq X \text{ open } :\ x \notin V \text{ or } V \not\subseteq Q$$

Thereby $V \not\subseteq Q$ means, there is some $y \in V$ with $y \notin Q$. And as $Q = X \setminus P$ this is $y \in P$. In other words there is some $y \in V$ with $y \in P$ and thereby $y \in V \cap P$, such that $V \cap P \neq \emptyset$. So let us rewrite the above statement with this in mind

$$\forall\, V \subseteq X \text{ open } :\ x \notin V \text{ or } V \cap P \neq \emptyset$$

In particular we can use this property for $V = F_n(x)$, as this is an open set in X. That is for any $n \in \mathbb{N}$ we have $x \notin F_n(x)$ or $F_n(x) \cap P \neq \emptyset$. As $F_n(x) \in \mathcal{T}(x)$ we have $x \in F_n(x)$ such that there has to be some $x_n \in F_n(x) \cap P$. As this is true for any $n \in \mathbb{N}$ we have found a sequence $(x_n) \subseteq P$. It only remains to prove $(x_n) \to_{\mathcal{F}} x$. That is we need to check that for all $m \in \mathbb{N}$ there has to be some $n(m) \in \mathbb{N}$, such that for any $n \geq n(m)$ we have $x_n \in F_m(x)$. But by construction we can take $n(m) := m$, then $x_n \in F_n(x) \subseteq F_m(x)$ for any $n \geq m$, such that $(x_n) \to_{\mathcal{F}} x$.

(vi) For the implication (a) $\implies$ (b) we start with a closed set $C \subseteq X$ and consider a convergent sequence $(x_n) \to_{\mathcal{F}} x$. Then by (v) we have $x \in \overline{C}$, but as C is closed this is $x \in C$, as$C = \overline{C}$, due to (6.16.(v)).

Conversely for (b) $\implies$ (a) we consider any $x \in \overline{C}$. By (v) this means $(x_n) \to x$ for some sequence $(x_n) \subseteq C$. But by assumption (b) this means $x \in C$ again and as this is true for any $x \in \overline{C}$, we have established $\overline{C} \subseteq C$. But $C \subseteq \overline{C}$ is generally true, by (6.16.(vi)) and hence $C = \overline{C}$. But by (6.16.(v)) this means that C is closed.

□

Proof of (6.23):

(i) As X is an open subset of X and $x \in X$ we have $X \in \mathcal{T}(x)$ and hence $X \in \mathcal{N}(x)$. In particular $\mathcal{N}(x) \neq \emptyset$. Also if $N \in \mathcal{N}(x)$ then there is some $U \in \mathcal{T}(x)$ with $U \subseteq N$. But as $x \in U$, by definition of $\mathcal{T}(x)$, this yields $x \in N$ and hence $N \neq \emptyset$. The upward closure property is obvious: If $N \in \mathcal{N}(x)$ and $N \subseteq P$, then there is some $U \in \mathcal{T}(x)$ with $U \subseteq N \subseteq P$ and hence $P \in \mathcal{N}(x)$, again. Finally let M, $N \in \mathcal{N}(x)$, then there are some U, $V \in \mathcal{T}(x)$, such that $U \subseteq M$ and $V \subseteq N$. As $U \cap V$ and $x \in U \cap V$, too, we have $U \cap V \subseteq \mathcal{T}(x)$. Also $U \cap V \subseteq M \cap N$ such that $M \cap N \subseteq \mathcal{N}(x)$ again, which means that $\mathcal{N}(x)$ is also colsed under finite intersections.

(ii) As $\mathcal{F} \neq \emptyset$, there is some $F \in \mathcal{F}$ and therefore $f(F) \in f(\mathcal{F})$, such that $f(\mathcal{F}) \neq \emptyset$, as well. Also for any $F \in \mathcal{F}$ there is some $x \in F$. Thereby $f(x) \in f(F)$, such that $f(F) \neq \emptyset$, again. Now to the upward closure property of $f(\mathcal{F})$: Consider any $F \in \mathcal{F}$ and any $Q \subseteq Y$ such that $f(F) \subseteq Q$. Then we have to prove $Q \in f(\mathcal{F})$ again. Let $P := f^{-1}(Q)$, if we start with $x \in F$, then $f(x) \in f(F) \subseteq Q$ such that $x \in f^{-1}(Q) = P$. That is we have $F \subseteq P$ and as $\mathcal{F}$ is a prefilter,

this means $P \in \mathcal{F}$, as well. Now recall (0.7), where we proved that

$$f(P) \;=\; f\big(f^{-1}(Q)\big) \;=\; f(X) \cap Q$$

As f is surjective, this means $f(P) = Q$ and as $P \in \mathcal{F}$ we have found $Q \in f(\mathcal{F})$ again. Now let $\mathcal{F}$ be a filter, then $X \in \mathcal{F}$ and thereby $Y = f(X) \in f(\mathcal{F})$, as well. Also consider any two F, $G \in \mathcal{F}$, then we need to show $f(F) \cap f(G) \in f(\mathcal{F})$ again. Let $E := F \cap G$ which is an element of $E \in \mathcal{F}$ again, as $\mathcal{F}$ is a filter. Then $f(E) \subseteq f(F) \cap f(G)$ is generally true. But as $f(E) \in f(\mathcal{F})$ the upward closure property guarantees $f(F) \cap f(G) \in f(\mathcal{F})$, again.

(iii) First of all, there is some $B \in \mathcal{B}$ and as $B \subseteq X$ we find $X \in \mathcal{F}$. Now consider any F with $B \subseteq F$ for some $B \in \mathcal{B}$. As any $B \in \mathcal{B}$ satisfies $x \in B$ we have $x \in B \subseteq F$ and thereby $x \in F$, such that $F \neq \emptyset$. The upward closure property is clear again: Given any $P \subseteq X$ with $F \subseteq P$ we have $B \subseteq F \subseteq P$, such that $P \in \mathcal{F}$ again. Now for finite intersections: Consider another $G \in \mathcal{F}$ such that $C \subseteq E$, for some $C \in \mathcal{B}$. Then by assumption there is some $A \in \mathcal{B}$, such that $A \subseteq B \cap C$ and thereby $A \subseteq B \cap C \subseteq F \cap G$, such that $F \cap B \in \mathcal{F}$ again.

(iii) If there is some $n \in \mathbb{N}$ such that $F_n(x) \subseteq N$, then we readily have $N \in \mathcal{N}(x)$, as $F_n(x) \in \mathcal{T}(x)$ by property (F1) of a system of local filters. Conversely if $N \in \mathcal{N}(x)$, then there is some $U \in \mathcal{T}(x)$ with $U \subseteq N$. And by property (F3) there is some $n \in \mathbb{N}$ such that $F_n(x) \subseteq U \subseteq N$. Thus N is contained in the set generated by $\mathcal{F}(x)$.

□

Proof of (6.24):

- For (a) $\implies$ (b) we start with some closed set $D \subseteq Y$, that is $D = Y \setminus V$ for some open set $V \subseteq Y$. By (0.7) we have $f^{-1}(Y \setminus V) = X \setminus f^{-1}(V)$ such that $f^{-1}(D) = X \setminus f^{-1}(V)$. But by (a) $f^{-1}(V) \subseteq X$ is open and hence $f^{-1}(D) = X \setminus f^{-1}(V) \subseteq X$ is closed. The converse direction (b) $\implies$ (a) recycles this idea: If $V \subseteq Y$ is open, then $D := Y \setminus V$ is closed, so $f^{-1}(D)$ is closed. That is $U := X \setminus f^{-1}(D)$ is open. But $f^{-1}(V) = f^{-1}(Y \setminus D) = X \setminus f^{-1}(D) = U$ and hence $f^{-1}(V)$ is an open set in X.

- For (a) $\implies$ (c) we note, that $Q^\circ \subseteq Y$ is open. Therefore $f^{-1}(Q^\circ) \subseteq X$ is open, too. Generally $Q^\circ \subseteq Q$ such that $f^{-1}(Q^\circ) \subseteq f^{-1}(Q)$. That is $f^{-1}(Q^\circ)$ is an open set contained in $f^{-1}(Q)$. As $f^{-1}(Q)^\circ$ is the union of all such sets, we conclude $f^{-1}(Q^\circ) \subseteq f^{-1}(Q)^\circ$.

 Conversely for (c) $\implies$ (a) we start with some open set $V \subseteq Y$. As V is open, we have $V = V^\circ$ and thereby by assumption (c) also $f^{-1}(V) = f^{-1}(V^\circ) \subseteq f^{-1}(V)^\circ \subseteq f^{-1}(V)$. Thus we have $f^{-1}(V) = f^{-1}(V)^\circ$, which means that $f^{-1}(V)$ is an open subset of X.

- Let us prove (b) $\implies$ (d), that is we start with an arbitrary subset $Q \subseteq Y$. As $\overline{Q}$ is closed, (b) tells us $f^{-1}(\overline{Q}) \subseteq X$ is closed, too. Also $Q \subseteq \overline{Q}$ is generally true such that $f^{-1}(Q) \subseteq f^{-1}(\overline{Q})$. That is $f^{-1}(\overline{Q})$ is a closed set containing $f^{-1}(Q)$. As $\overline{f^{-1}(Q)}$ is the intersection of all such sets, we conclude $\overline{f^{-1}(Q)} \subseteq f^{-1}(\overline{Q})$.

 Conversely for (d) $\implies$ (b), we start with some closed set $D \subseteq Y$. As D is closed, we have $D = \overline{D}$ and thereby by assumption (d) also $f^{-1}(D) \subseteq \overline{f^{-1}(D)} \subseteq f^{-1}(\overline{D}) = f^{-1}(D)$. Thus we have $f^{-1}(D) = \overline{f^{-1}(D)}$, which means that $f^{-1}(D)$ is a closed subset of X.

- Let us prove (a) $\implies$ (f), that is we start with some $x \in X$ and $V \in \mathcal{T}(f(x))$ and need to find $U \in \mathcal{T}(x)$ such that $f(U) \subseteq V$. As $V \subseteq Y$ is open, so is $U := f^{-1}(V)$. And as $f(x) \in V$ we also have $x \in U = \{\, x \in X \mid f(x) \in V \,\}$. As we also have $f(U) = f\big(f^{-1}(V)\big) \subseteq V$ by (0.7) we have found the open neighbourhood U of x required.

 Conversely we prove (f) $\implies$ (c): That is we start with any subset $Q \subseteq V$ and need to prove $f^{-1}(Q^\circ) \subseteq f^{-1}(Q)^\circ$. Recall that these sets are given to be

$$\begin{aligned} Q^\circ &= \{\, y \in Q \mid \exists\, V \in \mathcal{T}(y) : V \subseteq Q \,\} \\ f^{-1}(Q)^\circ &= \Big\{\, x \in f^{-1}(Q) \mid \exists\, U \in \mathcal{T}(x) : U \subseteq f^{-1}(Q) \,\Big\} \end{aligned}$$

 So consider any $x \in f^{-1}(Q^\circ)$, that is $y := f(x) \in Q^\circ$ which means that there is some $V \in \mathcal{T}(y)$ such that $V \subseteq Q$. Note that $Q^\circ \subseteq Q$ also implies $y = f(x) \in Q$ and hence $x \in f^{-1}(Q)$. As $y = f(x)$ we have $V \in \mathcal{T}(f(x))$ and hence our assumption (f) yields some $U \in \mathcal{T}(x)$ such that $f(U) \subseteq V$. Yet by (0.7) $f(U) \subseteq V$ is equivalent to $U \subseteq f^{-1}(V)$. And as $V \subseteq Q$ we have $f^{-1}(V) \subseteq f^{-1}(Q)$. Let us summarize: We have found some $U \in \mathcal{T}(x)$ with $U \subseteq f^{-1}(Q)$ and $x \in f^{-1}(Q)$. This means $x \in f^{-1}(Q)^\circ$ and as this is true for any $x \in f^{-1}(Q^\circ)$ we have proved the inclusion required for (c).

- Now to (b) $\implies$ (e), that is we start with an arbitrary subset $P \subseteq X$. As $\overline{f(P)} \subseteq Y$ is closed, our assumption (b) implies, that $f^{-1}(\overline{f(P)}) \subseteq X$ is closed, too. Note that we generally have $P \subseteq f^{-1}(f(P))$ by (0.7) and also $f(P) \subseteq \overline{f(P)}$ by (6.16.(vi)). Therefore $P \subseteq f^{-1}(f(P)) \subseteq f^{-1}(\overline{f(P)})$. And as the latter set is closed in X we find $\overline{P} \subseteq f^{-1}(\overline{f(P)})$. By (0.7) again, this equivalent to $f(\overline{P}) \subseteq \overline{f(P)}$, which if property (e), as required.

 Conversely we want to prove (e) $\implies$ (f), that is we start with any $x \in X$ and $V \in \mathcal{T}(f(x))$ and need to find some $U \in \mathcal{T}(x)$ with $f(U) \subseteq V$. This can be done in the following way: Let $C := X \setminus f^{-1}(V) = f^{-1}(Y \setminus V)$. We know $Y \setminus V \subseteq Y$ is closed, but we don't know (yet), that $C \subseteq X$ is closed, too. As $C \subseteq f^{-1}(Y \setminus V)$ (they even are equal) we get $f(C) \subseteq Y \setminus V$ by (0.7) once more. But as $Y \setminus V$ is closed this means $\overline{f(C)} \subseteq Y \setminus V$. By assumption (e) we have $f(\overline{C}) \subseteq \overline{f(C)} \subseteq Y \setminus V$. Now let $U := X \setminus \overline{C}$ which is an open set of X, as $\overline{C}$ is guaranteed to be closed. As $f(x) \in V$ and $f(\overline{C}) \subseteq Y \setminus V$ we have $x \notin \overline{C}$ which means $x \in U$. Thus $U \in \mathcal{T}(x)$ is an open neighbourhood of x. As $C \subseteq \overline{C}$ we have $U = X \setminus \overline{C} \subseteq X \setminus C = f^{-1}(V)$ by construction of C. But $U \subseteq f^{-1}(V)$ again is equivalent to $f(U) \subseteq V$, which is just what we needed.

- Let us first prove (g) $\implies$ (f): To do this we choose $\mathcal{F} = \mathcal{N}(x)$ and we begin with some open neighbourhood $V \in \mathcal{T}(f(x))$. In particular $N := V \cap f(X) \in \mathcal{N}(f(x)) \subseteq f(\mathcal{F})$. That is there is some $M \in \mathcal{N}(x)$ such that $f(M) = N$. Now $M \in \mathcal{N}(x)$ means there is some $U \in \mathcal{T}(x)$ with $U \subseteq M$ and thereby $f(U) \subseteq f(M) = N = V \cap f(X) \subseteq V$.

 In the converse direction (f) $\implies$ (g) we are given some prefilter $\mathcal{F}$ such that $\mathcal{N}(x) \subseteq \mathcal{F}$ and some $N \in \mathcal{N}(f(x))$ and need to show $N \in f(\mathcal{F})$. By definition $N \in \mathcal{N}(f(x))$ means that there is some $V \in \mathcal{T}(f(x))$ such that $V \cap f(x) \subseteq N$. By assumption (f) there is some $U \in \mathcal{T}(x)$ such that $f(U) \subseteq V$ and as $f(U) \subseteq f(X)$ is clear, we have $f(U) \subseteq V \cap f(X) \subseteq N$. By assumption we have $U \in \mathcal{T}(x) \subseteq \mathcal{N}(x) \subseteq \mathcal{F}$ such that $f(U) \in f(\mathcal{F})$. Let us summarize: We have $f(U) \subseteq N \subseteq f(X)$ for some $f(U) \in f(\mathcal{F})$ and by (6.23.(ii)) $f(\mathcal{F})$ is a prefilter on $f(X)$.

Thus by the upward closure property this implies $N \in f(\mathcal{F})$. And as this is true for any N we have shown $\mathcal{N}(f(x)) \subseteq f(\mathcal{F})$, as claimed.

□

Proof of (6.25):

- Let us start with (a) $\implies$ (c), that is we have f continuous and $(x_n) \to_{\mathcal{E}} x$ and need to show $(f(x_n)) \to_{\mathcal{F}} f(x)$. That is we are given some $m \in \mathbb{N}$ and need to find some $n(m) \in \mathbb{N}$ such that for any $n \geq n(m)$ we have $f(x_n) \in F_m(f(x))$. Let us abbreviate $y := f(x)$, as $F_m(y) \subseteq Y$ is open and f is continuous the set $f^{-1}(F_m(y)) \subseteq X$ is open, too. And as $f(x) = y \in F_m(y)$ this set contains x. Therefore, by (6.21.(i)), there is some $r(m)$ such that $E_{r(m)}(x) \subseteq f^{-1}(F_m(y))$. And by (0.7) this is equivalent, to $f(E_{r(m)}(x)) \subseteq F_m(y)$. As $(x_n) \to_{\mathcal{E}} x$ there is some $n(m) \in \mathbb{N}$ such that for any $n \geq n(m)$ we get $x_n \in E_{r(m)}(x)$. And by construction this turns into $f(x_n) \in F_m(y) = F_m(f(x))$. And this is exactly what we need, for $(f(x_n)) \to_{\mathcal{F}} f(x)$.

- In the next step we are concerned with (c) $\implies$ (b), that is for any $n \in \mathbb{N}$ and any $x \in X$ we need to find some $m \in \mathbb{N}$, such that $f(E_m(x)) \subseteq F_n(f(x))$. Equivalently $E_m(x) \subseteq f^{-1}(F_n(y))$, where $y := f(x)$ again. Suppose this was *not* the case, that is for any $m \in \mathbb{N}$ the set $E_m(x)$ is *not* contained in $f^{-1}(F_n(y))$. That is for any $m \in \mathbb{N}$ there is some x_m such that $x_m \in E_m(x)$ but $x_m \notin f^{-1}(F_n(y))$. Then by construction we have $(x_m) \to_{\mathcal{E}} x$ because of: Take $n(m) := m$ then for any $n \geq n(m)$ we have $x_n \in E_n(x) \subseteq E_m(x)$. Thus by assumption (c) we also get $(f(x_n)) \to_{\mathcal{F}} f(x) = y$. This means, that there is some $r(n) \in \mathbb{N}$ such that for any $r \geq r(n)$ we get $f(x_r) \in F_n(y)$. In particular $x_{r(n)} \in f^{-1}(F_n(y))$ in contradiction to $x_m \notin f^{-1}(F_n(y))$ for any $m \in \mathbb{N}$. Thus no such sequence can exist and this means $E_m(x) \subseteq f^{-1}(F_n(y))$ for some $m \in \mathbb{N}$.

- To close the circle we need to prove (b) $\implies$ (a), that is we are given an open set $V \subseteq Y$ and need to prove that $U := f^{-1}(V) \subseteq X$ is open. To do this choose any $x \in U$ and let $y := f(x)$. As $x \in U = f^{-1}(V)$ we get $y = f(x) \in V$. And as V is open (6.21.(i)) tells us, that there is some $n \in \mathbb{N}$ such that $F_n(y) \subseteq V$. By assumption (b) this means, that there is some $m \in \mathbb{N}$, such that $f(E_m(x)) \subseteq F_n(y)$ and by (0.7) this is $E_m(x) \subseteq f^{-1}(F_n(y)) \subseteq f^{-1}(V) = U$. Thus for any $x \in U$ there is some $m \in \mathbb{N}$ such that $E_m(x) \subseteq U$, then by (6.21.(i)) again we conclude, that $U \subseteq X$ is open and hence f continuous.

□

Proof of (6.29):

(i) Let us denote $f_0 : x \mapsto y_0$, then for any subset $V \subseteq Y$ we have $f_0^{-1}(V) = X$ if $y_0 \in V$ and $f_0^{-1}(V) = \emptyset$ if $y_0 \notin V$. In both cases $f_0^{-1}(V) \in \mathcal{T}_X$ such that f_0 is continuous.

(ii) Clearly for any subset $U \subseteq X$ we have $\mathbb{1}_x^{-1}(U) = U$. Thus if $\mathbb{1}_X$ is continuous, then for any $U \in \mathcal{T}_2$ we have $U = \mathbb{1}_x^{-1}(U) \in \mathcal{T}_1$. And as this is true for any U we get $\mathcal{T}_2 \subseteq \mathcal{T}_1$. Conversely if $\mathcal{T}_2 \subseteq \mathcal{T}_1$, then $\mathbb{1}_x^{-1}(U) = U \in \mathcal{T}_1$ for any $U \in \mathcal{T}_2$, which means that $\mathbb{1}_X$ is continuous.

(iii) If we start with some open set $W \subseteq Z$, then $V := g^{-1}(W) \subseteq Y$ is open, as g is continuous. Now, as f is continuous, $U := f^{-1}(V) \subseteq X$ is open, too. But $(gf)^{-1}(W) = f^{-1}(g^{-1}(W)) = f^{-1}(V) = U \in \mathcal{T}_X$, which means that gf is continuous.

(iv) We have to show that $f^{-1}(V) \subseteq X$ is open, for any $V \subseteq Y$ open. As $\mathcal{B}$ is a base of the topology, there is some $\{ B_i \mid i \in I \} \subseteq \mathcal{B}$, such that $V = \bigcup_i B_i$. But then we get $f^{-1}(V) = \bigcup_i f^{-1}(B_i)$ by (0.7) and by assumption any $f^{-1}(B_i) \subseteq X$ is open. But then, by (T4), $f^{-1}(V)$ is open, as it is a union of open sets.

(v) We have to show that $f(U) \subseteq Y$ is open, for any $U \subseteq X$ open. As $\mathcal{A}$ is a base of the topology, there is some $\{ A_i \mid i \in I \} \subseteq \mathcal{A}$, such that $U = \bigcup_i A_i$. But then we get $f(U) = \bigcup_i f^(A_i)$ by (0.7) and by assumption any $f(A_i) \subseteq Y$ is open. But then, by (T4), $f(U)$ is open, as it is a union of open sets.

(vi) We have to show that $f(C) \subseteq Y$ is closed, for any $C \subseteq X$ closed. Being closed means $C = X \setminus U$ for some $U \subseteq X$ open. As $\mathcal{A}$ is a base of the topology, there is some $\{ A_i \mid i \in I \} \subseteq \mathcal{A}$, such that $U = \bigcup_i A_i$. But then $C = X \setminus \bigcup_i A_i = \bigcap_i X \setminus A_i$. As f is injective (0.7) tells us, that $f(C) = \bigcap_i f(X \setminus A_i)$ by (0.7). By assumption any $f(X \setminus A_i) \subseteq Y$ is closed and hence $f(C)$ is closed, as it is an intersection of closed sets.

(vii) If Φ is a homeomorphism, then φ is bijective and continuous by definition. Also $\Phi^{-1} : Y \to X$ is continuous. Now for any subset $P \subseteq X$ we find the identity

$$\left(\Phi^{-1}\right)^{-1}(P) \;=\; \left\{ y \in Y \mid \Phi^{-1}(y) \in P \right\} \;=\; \{ y \in Y \mid y \in \Phi(P) \} \;=\; \Phi(P)$$

Thus if $U \subseteq X$ is open, then $\Phi(U) = (\Phi^{-1})^{-1}(P) \subseteq Y$ is open as Φ^{-1} is continuous. If conversely Φ is open, then $\Phi(U)$ is open, such that Φ^{-1} is continuous. Likewise of closed sets: Φ^{-1} is continuous iff $\Phi^{-1}(C) \subseteq Y$ is closed, for any closed set $C \subseteq X$. And due to this identity this is true iff $\Phi(C)$ is closed for any closed set $C \subseteq X$, which is Φ is closed.

(viii) We need to prove that $f(K) \subseteq Y$ is compact, whenever $K \subseteq X$ is compact. So we start with an arbitrary open covering $\{ V_i \mid i \in I \} \subseteq \mathcal{T}_Y$ of $f(K)$. As $V_i \subseteq Y$ is open, so is $U_i := f^{-1}(V_i) \subseteq X$. If we consider any $x \in K$ then $f(x) \in f(K) \subseteq \bigcup_i V_i$ that is $f(x) \in V_i$ for some $i \in I$ and this is $x \in f^{-1}(V_i) = U_i$. Thus we see $K \subseteq \bigcup_i U_i$ (where $i \in I$) and as K is compact there is some finite subset $\Omega \subseteq I$ such that $K \subseteq \bigcup_i U_i$ (where $i \in \Omega$). That is any $x \in K$ is contained in some $U_i = f^{-1}(V_i)$ for some $i \in \Omega$. This means $f(x) \in V_i$ and as this is true for any $y = f(x) \in f(K)$ we find $f(K) \subseteq \bigcup_i V_i$ (where $i \in \Omega$). That is we have find a finite sub-cover $\{ V_i \mid i \in \Omega \}$, which was required for $f(K)$ to be compact.

(ix) Let us first prove, that π_j is continuous. That is for any open set $U_j \subseteq X_j$ we have to show, that $\pi_j^{-1}(U_j)$ is open again. The more restrictive topology is the product topology, in this case. But as

$$\pi_j^{-1}(U_j) \;:=\; \prod_{i \in I} \begin{cases} U_j \text{ if } i = j \\ X_i \text{ if } i \neq j \end{cases}$$

we see, that π_j^{-1} even is a base set of the product topology and in particular, this is an open set in $\prod_i X_i$. Thus π_j is continuous. Let us now prove that π_j also is open. In this case the box topology is the more restrictive, as it contains more open set. So let us start with an open set $W \subseteq \prod_i X_i$ that is: For any $(x_i) \in W$ there is a family of open neighbourhoods $U_i \in \mathcal{T}_i(x_i)$ such

that $\prod_i U_i \subseteq W$. It is clear, that

$$\pi_j\left(\prod_{i\in I} U_i\right) \;=\; U_j$$

We need to show that $\pi_j(W) \subseteq X_j$ is open. If $W = \emptyset$, then $\pi_j(W) = \emptyset$, too, which is an open set in X_j. So we only need to consider $W \neq \emptyset$. To show that $\pi_j(W)$ is open, it suffices, that $\pi_j(W) \subseteq \pi_j(W)^\circ$. Thus we start with some $x_j \in \pi_j(W)$. As $W \neq \emptyset$ so is $\pi_i(W) \subseteq X_i$ for any $i \in I$. Hence, for any $i \neq j$, we may choose some $x_i \in \pi_i(W)$, and compose these x_i with x_j to a point $(x_i) \in W$. As W is open there is some (U_i) with $U_i \in \mathcal{T}_i(x_i)$ and $\prod_i U_i \subseteq W$. In particular

$$x_j \;\in\; U_j \;=\; \pi_j\left(\prod_{i\in I} U_i\right) \;\subseteq\; \pi_j(W)$$

This means $x_i \in \pi_j(W)^\circ$ and thereby $\pi_j(W) \subseteq \pi_j(W)^\circ$. As the converse inclusion is generally true, we have $\pi_j(W) = \pi_j(W)^\circ$, which means, that $\pi_j(W)$ is open.

(x) To prove that $\prod_i f_i$ is continuous we have to verify, that $f^{-1}(W) \subseteq X$ is open, for any open subset $W \subseteq \prod_i Y_i$. So let us take a closer look at the preimage of W:

$$\begin{aligned}
\left(\prod_{i\in I} f_i\right)^{-1}(W) &= \left\{\, x \in X \mid \left(f_i(x)\right) \in W \,\right\} \\
&= \left\{\, x \in X \mid \forall\, i \in I : f_i(x) \in \pi_i(W) \,\right\} \\
&= \left\{\, x \in X \mid \forall\, i \in I : x \in f_i^{-1}\left(\pi_i(W)\right) \,\right\} \\
&= \bigcap_{i\in I} f_i^{-1}\left(\pi_i(W)\right)
\end{aligned}$$

If I is finite, the argument is easy: As W is open and any π_i is an open map, by (iv) we see that $\pi_i(W)$ is open. Also f_i is continuous and hence $f_i^{-1}(\pi_i(W)) \subseteq X$ is open. But a *finite* intersection of open sets is open again and hence the preimage of W under $\prod_i f_i$ is an open subset of X. This means $\prod_i f_i$ is continuous.

In case I is infinite we need to take a closer look at the product topology (and $\prod_i f_i$ need not be continuous if $\prod_i X_i$ is bestowed with the box topology): As W is open any point $y = (y_i) \in W$ is contained in a base set $\prod_i U_i \subseteq W$. For any $y \in W$ let $B(y) = \prod_i U_i(y) \in \mathcal{B}$ be some base set of the product topology, such that $y \in B(y) \subseteq W$. Then we get

$$W \;=\; \bigcup_{y\in W} B(y) \;=\; \prod_{i\in I}\left(\bigcup_{y\in W} U_i(y)\right)$$

Let $S(B(y)) := \{\, i \in I \mid U_i(y) \neq X_i \,\}$ be the set of indices for which $U_i(y)$ is not the entire space X_j. By construction of the product topology $S(B(y))$ is finite for any $y \in Y$. Also if $U_i(z) = X_i$ for some $z \in W$, then the union $\bigcup_y U_i(y) = X_i$ is full, as well. Thus $S(W) = \bigcap_y S(B(y))$ is contained in any $S(B(y))$ and hence finite, too. For any $i \notin S(W)$ we have $\pi_i(W) = \bigcup_y U_i(y) = X_i$ and hence $f_i^{-1}(\pi_i(W)) = X$. Thus no $i \notin S(W)$ contributes to the intersection above, the intersection runs over a finite subset of I only. And for finite sets I we already gave an argument. Thus in the product topology the preimage of W under $\prod_i f_i$ is an open subset of X, even if I is infinite.

(xi) For any $i \in I$ with $i \neq j$ let us denote the constant function $f_i : X_j \to X_i : x_j \mapsto a_i$. Then f_i is continuous, by (i). And for $i = j$ pick up the identity $\mathbb{1}_j : X_j \to X_j : x_j \mapsto x_j$. As both copies of X_j carry the same topology $\mathcal{T}_j$, the identity is continuous, according to (ii). Then by (vii) we find, that ι_j is continuous, as it is the product of

$$\iota_j \;=\; \prod_{i\in I} \begin{cases} \mathbb{1}_j \text{ if } i = j \\ f_i \text{ if } i \neq j \end{cases}$$

□

Proof of (6.31):

(i) We first have to prove that the final topology truly is a topology on Y: Clearly $f_i^{-1}(Y) = X_i$ and $f_i^{-1}(\emptyset) = \emptyset \subseteq X_i$ for any $i \in I$ such that Y and $\emptyset \subseteq Y$ are open. If now V_1 and $V_2 \subseteq Y$ are open sets, then $U_k := f_i(V_k) \subseteq X_i$ are open for any $i \in I$ and $k \in \{1,2\}$. But thereby

$$f_i^{-1}(V_1 \cap V_2) \;=\; f_i^{-1}(V_1) \cap f_i^{-1}(V_2) \;=\; U_1 \cap U_2 \;\subseteq\; X_i \text{ open}$$

as $\mathcal{T}_i$ is closed under finite intersections. Thereby $V_1 \cap V_2 \subseteq Y$ is open again. In complete analogy, for any index set K and open sets $V_k \subseteq X_i$ (where $k \in K$ and $U_k := f_i(V_k) \subseteq X_i$ again) we get by (0.7)

$$f_i^{-1}\left(\bigcup_{k\in K} V_k\right) \;=\; \bigcup_{k\in K} f_i^{-1}(V_k) \;=\; \bigcup_{k\in K} U_k \;\subseteq\; X_i \text{ open}$$

as $\mathcal{T}_i$ is closed under arbitrary unions. Again this means, that the union of the V_k is open in Y again. Altogether we have verified that we truly have a topology on Y. The fact that any f_i is continuous is just the construction of this topology: Consider any $i \in I$ and any open set $V \subseteq Y$. We have to show that $f_i^{-1}(V) \subseteq X_i$ is open. But this has just been the definition of "open" in Y.

(i) Now to the second part of (i), the equivalence of (a) and (b) for any map $g : Y \to Z$: If (a), then by (6.29.(iii)) the map $gf_i : X_i \to Z$ is continuous, too. Conversely, if (b) then we have to check that $g^{-1}(W) \subseteq Y$ is open, for any open subset $W \subseteq Z$. By definition $g^{-1}(W)$ is open iff for any $i \in I$ the set $f_i^{-1}(g^{-1}(W)) \subseteq X_i$ is open. But

$$f_i^{-1}\big(g^{-1}(W)\big) \;=\; (gf_i)^{-1}(W)$$

and gf_i is continuous by assumption (b). Thus $(gf_i)^{-1}(W) \subseteq X_i$ is an open subset and as this is true for any $i \in I$ we see that $g^{-1}(W) \subseteq Y$ is open. As this is true for any open $W \subseteq Z$ we have found g to be continuous, which is (a).

(ii) Note that $\varrho^{-1}(V) = \{\, x \in X \mid \varrho(x) \in V \,\} = \{\, x \in X \mid [x] \in V \,\}$ such that the quotient topology truly is a special case of a final topology for the single map ϱ only. If $P \subseteq X$ is any subset, then

$$\varrho^{-1}\big(\varrho(P)\big) \;=\; \varrho^{-1}\big(\,\{\,[p] \mid p \in P\,\}\,\big) \;=\; \{\, x \in X \mid \exists\, p \in P : x \in [p] \,\} \;=\; \bigcup_{p\in P} [p]$$

Clearly we have $\varrho([x]) = \{\,[y] \mid y \in [x]\,\} = \{\,[x]\,\}$. And by definition of the quotient topology $\{\,[x]\,\}$ is open, if and only if $\varrho^{-1}(\{\,[x]\,\}) \subseteq X$ is open. But this is $\varrho^{-1}(\{\,[x]\,\}) = \varrho^{-1}(\varrho([x])) =$

$\bigcup \{ [x] \} = [x]$. Hence $\{ [x] \} \subseteq X/\sim$ is open, if and only if $[x] \subseteq X$ is open.

□

Proof of (6.30):
First of all f is well-defined: If $x \in X_i$ and $x \in X_j$ then $x \in X_i \cap X_j$ and hence $f_i(x) = f_j(x)$ by assumption. That is the value $f(x)$ is uniquely determined, and it exists, as the X_i cover X. Further for any subset $B \subseteq Y$ it is clear that

$$\begin{aligned} f^{-1}(B) &= \{ x \in X \mid f(x) \in B \} = \{ x \in X \mid \exists\, i \in I : x_i \in X_i \text{ and } f_i(x) \in B \} \\ &= \bigcup_{i \in I} \{ x \in X_i \mid f_i(x) \in B \} = \bigcup_{i \in I} f_i^{-1}(B) \end{aligned}$$

(i) thus if $V \subseteq Y$ is open, then any $f_i^{-1}(V) \subseteq X_i$ is open, as f_i is continuous. And as $X_i \subseteq X$ is open, too we get that $f_i^{-1}(V) \subseteq X$ is open. Thus the same is true for the union $f^{-1}(V) = \bigcup_i f_i^{-1}(V) \subseteq X$ and hence f is continuous. (ii) if $D \subseteq Y$ is closed then $f_i^{-1}(D) \subseteq X_i$ is closed again, and as $X_i \subseteq X$ is closed this implies, that $f_i^{-1}(D) \subseteq X$ is closed. Therefore the same is true for the *finite* union $f^{-1}(D) = \bigcup_i f_i^{-1}(D) \subseteq X$. Again this means that f is continuous. □

Proof of (6.33):

(i) Clearly $X_i \cap X_i = X_i \subseteq X_i$ is open, and due to property (2) we find (for any $j \neq i$) that $X_i \cap X_j = \emptyset \subseteq X_j$ is open, too. Thus by property (3) $X_i \subseteq X$ is open. Now apply properties (1) and (2) to see that $X \setminus X_i = \bigcup_j X_j \setminus X_i = \bigcup_{j \neq i} X_j$ is open, too and hence $X_i \subseteq X$ also is closed.

(ii) (a) $\Longrightarrow$ (b): If $X = A \oplus B$, then $X = A \cup B$ and $A \cap B = \emptyset$, by definition of the topological sum. And we have already seen in (i), that A and B are both, open and closed. Now as A and B are closed, this yields $\overline{A} \cap B = A \cap B = \emptyset$ and likewise $A \cap \overline{B} = \emptyset$.

(ii) (b) $\Longrightarrow$ (c): Conversely $X = A \cup B \subseteq \overline{A} \cup B \subseteq X$ implies $X = \overline{A} \cup B$. And as also $\overline{A} \cap B = \emptyset$ this yields $B = X \setminus \overline{A}$ and hence B is open. Interchanging A and B we find, that A is open, too. Next note that $\emptyset \subseteq A \cap B \subseteq \overline{A} \cap B = \emptyset$ implies $A \cap B = \emptyset$. And as $X = A \cup B$ this yields $B = X \setminus A$ and hence B is closed, too. Interchanging A and B again, we find, that A is open and closed, as well.

(ii) (c) $\Longrightarrow$ (a): We only have to verify property (3): If $U \subseteq X$ is open, then $U \cap A \subseteq A$ and $U \cap B \subseteq B$ are open, by definition of the relative topology. Conversely if $U \cap A \subseteq A$ and $U \cap B \subseteq B$ are open then there are open subsets V_A and $V_B \subseteq X$ such that $U \cap A = V_A \cap A$ and $U \cap B = V_B \cap B$. And thereby $U = U \cap X = U \cap (A \cup B) = (U \cap A) \cup (U \cap B) = (V_A \cap A) \cup (V_B \cap B)$. Yet as all of the sets A, B, V_A and V_B are open in X, we find that U is open in X, too.

(iii) If $X = X_1 \oplus X_2$ then by (i) the $X_i \subseteq X$ are open and closed. And by definition of the relative topology this means that $A_i = X_i \cap A \subseteq A$ is open and closed, too. Now $A_1 \cap A_2 \subseteq X_1 \cap X_2 = \emptyset$ is clear. And likewise $A = A \cap X = A \cap (X_1 \cup X_2) = (A \cap X_1) \cup (A \cap X_2) = A_1 \cup A_2$. Thus by (ii) (c) $\Longrightarrow$ (a) we found $A = A_1 \oplus A_2$ again.

(iv) If $Y = Y_1 \oplus Y_2$, then by (i) the $Y_i \subseteq Y$ are open and closed. And as f is continuous, this yields that $X_i = f^{-1}(Y_i) \subseteq X$ is open and closed again. We also find $X = f^{-1}(Y) = f^{-1}(Y_1 \cup Y_2) =$

$f^{-1}(Y_1) \cup f^{-1}(Y_2) = X_1 \cup X_2$. And in complete analogy we also find $\emptyset = f^{-1}(\emptyset) = f^{-1}(Y_1 \cap Y_2) = f^{-1}(Y_1) \cap f^{-1}(Y_2) = X_1 \cap X_2$. Thus by (ii) (c) $\implies$ (a) we get $X = X_1 \oplus X_2$ again.

□

Proof of (6.34):

- (a) $\implies$ (b): If $X = X_1 \oplus X_2$ then by (6.33.(i)) we find, that $X_1 \subseteq X$ is both, open and closed. Thus by assumption (a) we get $X_1 = \emptyset$ or $X_1 = X$. Now it suffices to note that $X_1 = \emptyset$ yields $X_2 = X \setminus X_1 = X$, such that either $X_1 = X$ or $X_2 = X$.
- (b) $\implies$ (c): If $X = A \cup B$ for sume subsets $A, B \subseteq X$ with $\overline{A} \cap B = \emptyset = A \cap \overline{B}$, then by (6.33.(ii)) we get $X = A \oplus B$. Thus by assumption we already have $A = X$ or $B = X$.
- (c) $\implies$ (d): We have to verify $\partial A = \emptyset \implies A \in \{\emptyset, X\}$. Thus assume $\partial A = \emptyset$, that is $A^\circ = \overline{A}$. Then we find that $A^\circ = A = \overline{A}$ from $A^\circ \subseteq A \subseteq \overline{A} = A^\circ$. Hence A is closed (as $A = \overline{A}$) and open (as $A = A^\circ$). Thereby $B := X \setminus A$ is open and closed, as well. Hence $\overline{A} \cap B = A \cap B = \emptyset$ and $A \cap \overline{B} = A \cap B = \emptyset$. And as $X = A \cup B$, is clear the pair (A, B) satisfies the condition in the assumption (c). Thus we get $A = X$ or $B = X$. But now it suffices to note that $B = X$ implies $A = X \setminus B = \emptyset$. Thus we have either $A = X$ or $A = \emptyset$, as claimed.
- (d) $\implies$ (a): suppose $A \subseteq X$ is both, open and closed. Then we find $A^\circ = A = \overline{A}$ and hence $\partial A = \emptyset$. By assumption (d) this means $A \in \{\emptyset, X\}$, which had to be shown.

□

Proof of (6.35):

(i) In order to have a precise notation let $\mathrm{cl}_X(A)$ denote the closure of A in the topology of X and $\mathrm{cl}_C(A \cap C)$ the closure of $A \cap C$ in the relative topology of C. We have seen in (6.16.(x)) that $\mathrm{cl}_C(A \cap C) = \mathrm{cl}_X(A \cap C) \cap C$ and hence we get $\mathrm{cl}_C(A \cap C) \subseteq \mathrm{cl}_X(A) \cap C \subseteq \mathrm{cl}_X(A)$ such that

$$\mathrm{cl}_C(C \cap A) \cap (C \cap B) \subseteq \mathrm{cl}_X(A) \cap B \cap C = \emptyset$$

and hence $\overline{(C \cap A)} \cap (C \cap B) = \emptyset$ (where the closure now refers to the relative topology of C). Repeating the argument with B instead of A, we find $(C \cap A) \cap \overline{(C \cap B)} = \emptyset$. But as $C \subseteq A \cap B$ we clearly have $C = (C \cap A) \cup (C \cap B)$. Thus by property (c) of the connected set C we have $C \cap A = C$ or $C \cap B = C$. But this means nothing but $C \subseteq A$ or $C \subseteq B$, which had to be shown.

(iii) We will prove that $S := \bigcup \mathcal{C}$ is connected by verifying property (c) of connected sets. Thus assume we had some subsets $A, B \subseteq S$ such that $S = A \cup B$ and $\mathrm{cl}_S(A) \cap B = \emptyset = A \cap \mathrm{cl}_S(B)$ (where the subscript S denotes that the closure is taken in S). Now recall that $\mathrm{cl}_S(A) = \mathrm{cl}_X(A) \cap S$. Thus for any $C \in \mathcal{C}$ we have $\mathrm{cl}_X(A) \cap B \cap C \subseteq \mathrm{cl}_X(A) \cap B \cap S = \mathrm{cl}_S(A) \cap B = \emptyset$ and likewise $A \cap \mathrm{cl}_X(B) \cap C = \emptyset$. As $C \subseteq S = A \cup B$ (i) now implies $C \subseteq A$ or $C \subseteq B$. Now fix some $C \in \mathcal{C}$, where we assume $C \subseteq A$ without loss of generality. In particular $\mathrm{cl}_X(C) \subseteq \mathrm{cl}_X(A)$ and as $B \subseteq S$ we hence get $\mathrm{cl}_X(C) \cap B \subseteq \mathrm{cl}_X(A) \cap B = \mathrm{cl}_X(A) \cap B \cap S = \mathrm{cl}_S(A) \cap B$. Suppose we had $D \subseteq B$ for some other $D \in \mathcal{C}$, then $\emptyset \neq \bigcap \mathcal{C} \subseteq C \cap D \subseteq \mathrm{cl}_X(C) \cap D \subseteq \mathrm{cl}_X(C) \cap B \subseteq \mathrm{cl}_S(A) \cap B = \emptyset$, a contradiction. Thus we found $D \subseteq A$, as well and as D has been arbitrary this yields $S = \bigcup \mathcal{C} \subseteq A \subseteq S$ and hence $S = A$. Thus S is connected again. And clearly (ii) is a special case of (iii), considering $\mathcal{C} := \{C, D\}$.

(iv) Consider any partition of A into a topological sum $A = A_1 \oplus A_2$ and let us denote $C_i := A_i \cap C$. Then by (6.33.(iii)) we find that $C = C_1 \oplus C_2$. Yet as C was assumed to be connected this implies $C_1 = \emptyset$ or $C_2 = \emptyset$. Without loss of generality we regard the case $C_1 = \emptyset$ only. As $C \subseteq A = A_1 \cup A_2$ this implies $C \subseteq A_2$ and hence $A_1 \subseteq A \subseteq \overline{C} \subseteq \overline{A}_2$. Hence $A_1 = A_1 \cap \overline{A}_2 = A_1 \cap \overline{A}_2 \cap A = A_1 \cap \overline{A}_{2,A} = A_1 \cap A_2 = \emptyset$ (where $\overline{A}_{2,A}$ denotes the closure of A_2 in A, which is A_2 again, as $A_2 \subseteq A$ is closed). Thus we have proved $A_1 = \emptyset$ and hence $A_2 = X$. And as the partition has been arbitrary this means, that A is connected, again.

(v) Suppose $f(C)$ was *not* connected, then by property (b) there are some subsets $F_1, F_2 \subseteq f(C)$ such that $f(C) = F_1 \oplus F_2$ and $F_1, F_2 \neq \emptyset$. Now regard $f : C \to f(C)$, which is a continuous function again and let $C_i := (f\big|_C)^{-1}(F_i) = f^{-1}(F_i) \cap C$. Then by (6.33.(iv)) we find $C = C_1 \oplus C_2$ and as C is connected this implies $C_1 = \emptyset$ or $C_2 = \emptyset$. But on the other hand $F_i \neq \emptyset$ is non-empty, there is some $y_i \in F_i \subseteq f(C)$ and hence some $x_i \in C$ such that $f(x_i) = y_i$. Now $x_i \in C_i$ is clear and hence $C_i \neq \emptyset$ is non-empty, as well. Thus we have obtained a contradiction, which can only be evaded if $f(C)$ is connected.

□

Proof of (6.36):

- We will first prove that $\sim$ truly is an equivalence relation. *Reflexivity*: for any $x \in X$ the set $\{ x \}$ clearly is connected, as the trivial subsets $\emptyset$ and $\{ x \}$ are the only subsets of $\{ x \}$ available. Now $\{ x, x \} \subseteq \{ x \}$ implies $x \sim x$. *Symmetry*: If $x \sim y$, then by definition there is some connected set $C \subseteq X$, such that $\{ x, y \} \subseteq C$. But as $\{ y, x \} = \{ x, y \} \subseteq C$ this already implies $y \sim x$. *Transitivity*: If $x \sim y$ and $y \sim z$ then there are connected sets $C, D \subseteq X$ such that $\{ x, y \} \subseteq C$ and $\{ y, z \} \subseteq D$. Hence $y \in C \cap D$ such that by (6.35.(ii)) $C \cap D$ is connected again. Now, as $\{ x, z \} \subseteq C \cap D$, this yields $x \sim z$.

- It remains to verify that $[x] = \bigcup \{ C \subseteq X \text{ connected} \mid x \in C \}$. For "$\supseteq$" we are given any connected set $C \subseteq X$ such that $x \in C$ and need to verify, that $C \subseteq [x]$. Thus consider any $y \in C$, then $\{ x, y \} \subseteq C$ and hence $x \sim y$, which translates into $y \in [x]$ again. As y has been arbitrary, we truly have $C \subseteq [x]$. Conversely for "$\subseteq$" consider any $y \in [x]$. That is $x \sim y$ and hence there is some connected set $C \subseteq X$ such that $\{ x, y \} \subseteq C$. In particular $x \in C$ and hence $C \in \{ C \subseteq X \text{ connected} \mid x \in C \}$. And as $y \in C$ (and y has been arbitrary) this yields the converse inclusion.

□

Proof of (6.37):

(i) Let us first prove that a connected component $K = \mathrm{cnc}(x)$ is connected [we would speak of a poor name choice, if this was not the case]: Let $\mathcal{C}(x) := \{ C \subseteq X \mid C \text{ connected}, x \in C \}$, then $\{ x \} \in \mathcal{C}(x)$ and $x \in \bigcap \mathcal{C}(x)$. Thus $\mathcal{C}(x)$ is non-empty and has non-empty intersection, such that (6.35.(iii)) tells us, that $\bigcup \mathcal{C}$ is connected again. And by (6.36) we already know $K = \bigcup \mathcal{C}(x)$. We have to postpone the proof, that K already is closed.

(ii) "$\subseteq$": Suppose $K = \mathrm{cnc}(x)$ is a connected component of X, then we need to show that K is maximal among the connected subsets of X. By (i) we know, that K is connected, so it remains to show the

maximality of E: Suppose $K \subseteq C$ for some $C \subseteq X$ connected and consider $y \in C$. Then (as also $x \in C$) $\{x,y\} \subseteq C$ and as C is connected this implies $x \sim y$ and hence $y \in [x] = K$. Thus as y has been arbitrary we found $C \subseteq K$, too and hence $C = K$, which is the maximality of K.

(ii) "$\supseteq$": Conversely suppose K is maximal among the connected subsets of X, then we need to show, that K is a connected component. If $K = \emptyset$, then already $X = \emptyset$ (as for any $x \in X$ the set $\{x\}$ would be a connected set truly larger than $K = \emptyset$) in contradiction to the assumption. Thus there is some element $x \in K$. Next we will show

$$K \;=\; \mathrm{cnc}(x)$$

in particular K is a connected component. The inclusion $K \subseteq \mathrm{cnc}(x)$ is easy: If $y \in K$ then $\{x,y\} \subseteq K$ and as K is connected, this means $x \sim y$ and hence $y \in [x] = \mathrm{cnc}(x)$. Conversely consider any element $y \in \mathrm{cnc}(x)$, that is $x \sim y$ and hence there is some connected set $C \subseteq X$ such that $\{x,y\} \subseteq C$. Hence $x \in C \cap K$ and as both C and K are connected, so is $C \cup K$, according to (6.35.(ii)). But as K was assumed to be maximal and $K \subseteq C \cup K$ is clear, we get $K = K \cup C$, which is $C \subseteq K$. In particular $y \in C \subseteq K$ yields $y \in K$.

(i) Now we are ready to prove that the connected components also are closed: Let $K = \mathrm{cnc}(x)$ be a connected component again. As $K \subseteq \overline{K} \subseteq \overline{K}$ (6.35.(iv)) implies that $\overline{K}$ is connected again. Now combining $K \subseteq \overline{K}$ with the maximality of K we find $K = \overline{E}$, that is K is closed, as well.

(iii) By assumption we have $X \neq \emptyset$. If $C = \emptyset$ then we choose some arbitrary $x \in X$ and let $K := \mathrm{cnc}(x)$. Then K is a connected component and $C \subseteq K$ is clear. Thus we may continue with the case $C \neq \emptyset$. Then we regard the set

$$\mathcal{Z} \;:=\; \{\, D \subseteq X \mid D \text{ connected, } C \subseteq D \,\}$$

As C is connected we have $C \subseteq \mathcal{Z}$ and hence $\mathcal{Z} \neq \emptyset$. Clearly $\mathcal{Z}$ is partially ordered under "$\subseteq$". To apply the lemma of Zorn we have to regard a chain $(D_i) \subseteq \mathcal{Z}$ (where $i \in I$) and find an upper bound for it. Of course our candidate for an upper bound is

$$D \;:=\; \bigcup_{i \in I} D_i$$

Clearly $C \subseteq D_i \subseteq D$ for any $i \in I$ and hence we have to show that D is connected again. Thus consider some decomposition of D as a topological sum $D = D' \oplus D''$. For any $i \in I$ let us denote $D'_i := D_i \cap D'$ and $D''_i := D_i \cap D''$. Then by (6.33.(iii)) we get $D_i = D'_i \oplus D''_i$ again. Yet as the D_i are connected this implies $D'_i = D_i$ or $D''_i = D_i$. Suppose there were some i, $j \in I$ such that $D'_i = D_i$ and $D''_j = D_j$. As (D_i) is a chain we may assume $D_i \subseteq D_j$. Therefore $D_i = D'_i = D_i \cap D' \subseteq D_j \cap D' = D'_j = D_j \setminus D''_j = \emptyset$. That is $D_i = \emptyset$, which cannot be, as $\emptyset \neq C \subseteq D_i$. Thus all the D_i are either equal to D'_i or to D''_i and they all agree which of the two cases is satisfied. Without loss of generality we may assume $D_i = D'_i$ for any $i \in I$. Now $D = \bigcup_i D_i = \bigcup_i D'_i = \bigcup_i D_i \cap D' = D \cap D' = D'$. And as the decomposition has been arbitrary this proves, that D is connected again. Thus by the lemma of Zorn, there is a maximal element $K \in \mathcal{Z}$. And by (ii) it is clear, that any such is a connected component of X. Thus it remains to verify

the uniqueness of K. Suppose $C \subseteq K$ and $C \subseteq L$ for some connected components $K = \text{CNC}(x)$ and $L = \text{CNC}(z)$ and choose any $y \in C$. As $\{x,y\} \subseteq K$ we have $x \sim y$ and likewise $y \sim z$, as $\{y,z\} \subseteq L$. Thus $x \sim z$ and this means $K = [x] = [y] = L$.

(iv) As $\sim$ is an equivalence relation the K_i partition X, that is we have $X = K_1 \cup \cdots \cup K_n$ and $K_i \cap K_j = \emptyset$ for any $i \neq j \in 1 \ldots n$. As we have seen in (i) any $K_i \subseteq X$ is closed. But as the K_i partition X we have $X \setminus K_i = \bigcup_{j \neq i} K_j$, which is a closed set. Thus all of the $K_i \subseteq X$ are open, too. Using (6.33.(ii)) (and induction on n) we finally find the claim $X = K_1 \oplus \cdots \oplus K_n$.

□

Proof of (6.39):

- Let us prove the equivalence of (a) and (c) first: Consider any subset $P \subseteq G$ then $\lambda_x^{-1}(P) = \{ y \in G \mid xy \in P \} = \{ y \in G \mid y \in x^{-1}P \} = x^{-1}P$. Thus if for any $x \in G$ the map λ_x is continuous, then $\lambda_{x^{-1}}$ is continuous, too. So if $U \subseteq G$ is open, then $\lambda_{x^{-1}}^{-1}(U) = xU \subseteq G$ is open, too. Conversely if for any $x \in G$ the coset $xU \subseteq G$ is open, then the same is true for $x^{-1}U = \lambda_x^{-1}(U)$. And this means λ_x is continuous. The same reasoning shows the equivalence of μ_y being continuous and Uy being open again (for any $y \in G$).

- The equivalence of (a) and (d) follows in the same way: Note that λ_x is continuous, iff for any closed set $C \subseteq G$ the preimage $\lambda_x^{-1}(C) = x^{-1}C \subseteq G$ is closed again. Hence if for any $x \in G$ the map λ_x is continuous, then $\lambda_{x^{-1}}$ is continuous, too. So if $C \subseteq G$ is closed, then $\lambda_{x^{-1}}^{-1}(C) = xC \subseteq G$ is closed, too. Conversely if for any $x \in G$ the coset $xC \subseteq G$ is closed, then the same is true for $x^{-1}C = \lambda_x^{-1}(C)$. And this means λ_x is continuous. The same reasoning shows the equivalence of μ_y being continuous and Cy being closed again (for any $y \in G$).

- Now to the equivalence of (b) and (e): By definition $\circ$ is continuous, iff for any $W \subseteq G$ open $\circ^{-1}(W) = \{ (x,y) \in G^2 \mid xy \in W \}$ is an open subset of $G^2 = G \times G$. As G^2 carries the box topology this means that for any $(x,y) \in \circ^{-1}(W)$ there are some $U \in \mathcal{T}(x)$ and $V \in \mathcal{T}(y)$ such that $U \times V \subseteq \circ^{-1}(W)$. Now we replace $(x,y) \in \circ^{-1}(W)$ by "x, $y \in G$ with $xy \in W$" and $U \times V \subseteq W$ by "for any $u \in U$ and $v \in V$ we get $uv \in W$". Then this is statement (e) precisely.

- Now to (b) $\implies$ (a): Fix $x \in G$ and regard the embedding $\iota_x : G \to G^2 : y \mapsto (x,y)$. Let us prove, that this map is continuous, that is if $W \subseteq G^2$ is an open set, then $\iota_x^{-1}(W) = \{ y \in G \mid (x,y) \in W \} \subseteq G$ is open, too. To do this fix any $y \in \iota_x^{-1}(W)$, as $(x,y) \in W$ the definition of the box topology tells us, that there are some $U \in \mathcal{T}(x)$ and $V \in \mathcal{T}(y)$, such that $U \times V \subseteq W$. As $x \in U$ in particular $\iota_x(v) = (x,v) \in W$ for any $v \in V$. And as this is true for any $v \in V$ we have $y \in V \subseteq \iota_y^{-1}(W)$. As we have found such an open set V for any $y \in \iota_y^{-1}(W)$, this means, that $\iota_x^{-1}(W)$ is open, by (6.16.(ix)).

 Now that ι_x is continuous, we note that $\lambda_x(y) = xy = \circ\iota_x(y)$, that is $\lambda_x = \circ\iota_x$ is a composition of continuous maps and hence continuous itself. Analogously $\mu_y = \circ\iota_y$ where $\iota_y(x) := (x,y)$ is continuous, too. For the same reason μ_y is continuous for any $y \in G$.

- We finish by proving (e) $\implies$ (c), that is we regard any $W \subseteq G$ open and need to show that for any x, $y \in G$ the cosets xW and Wy are open again. As this should be true for any x, $y \in G$, let us prove that $x^{-1}W$ and Wy^{-1} are open, instead. If $W = \emptyset$, then $x^{-1}W$ and $Wy^{-1} = \emptyset$ which

is open. So we consider $W \neq \emptyset$ and fix any $x \in G$ and $y \in x^{-1}W$. That is $xy \in W$ and hence, by assumption (e), there are some $U \in \mathcal{T}(x)$ and $V \subseteq \mathcal{T}(y)$ such that for any $u \in U$ and $v \in V$ we have $uv \in W$. In particular for $u = x$ this is $v \in x^{-1}W$. As this is true for any $v \in V$ we have $V \subseteq x^{-1}W$ and $y \in V$. As this is true for any $y \in x^{-1}W$ we know that $x^{-1}W$ is open, by (6.16.(ix)). In the same way it can be seen, that Wy^{-1} is open.

□

Proof of (6.41):

- The first thing to do is check the well-definedness of the metric: Consider any $x, y \in G$ with $x \neq y$ and let $N := \{ k \in \mathbb{N} \mid x - y \in F_k \}$. As $x - y \in G = F_0$ we generally have $0 \in N$, such that N is non-empty. Also, if $m \notin N$, then for any $n \geq m$ we have $F_n \subseteq F_m$ such that $x - y \notin F_m$ also implies $x - y \notin F_n$. Thus $m \notin N$ implies $n \notin N$ for any $n \geq m$. Suppose we had $N = \mathbb{N}$, then $x - y$ would be contained in the intersection $\bigcap_n F_n = \{0\}$. As $x \neq y$ this cannot be and hence there is some $m \in \mathbb{N}$ such that $x - y \notin F_m$. As we have just argued, this implies $n \notin N$ for any $n \geq m$ and thereby $N \subseteq 0 \ldots (m-1)$. In particular N is a finite, non-empty set and thereby it has a maximum.

- Before proving that d is a metric, let us verify that $x + F_m$ is a closed ball of radius 2^{-m}. That is d satisfies the property: $x + F_m = \{ y \in G \mid d(x,y) \leq 2^{-m} \}$. For the inclusion from left to right we start with some $f \in F_m$ and have to show $d(x, x+f) \leq 2^{-m}$. If $f = 0$, then $d(x, x+f) = 0 \leq 2^{-m}$. If $f \neq 0$ we have $d(x, x+f) = 2^{-n}$ where $n = \max\{ k \in \mathbb{N} \mid x - (x+f) \in F_k \}$. Hereby $x - (x+f) = -f \in F_m$, such that m is contained in this set. In particular $n \geq m$ and thereby $d(x, x+f) = 2^{-n} \leq 2^{-m}$. Conversely from right to left, we have $d(x,y) \leq 2^{-m}$. If $x = y$ then $y = x + 0 \in x + F_m$ is granted. If $x \neq y$ let $d(x,y) = 2^{-n}$ where $n = \max\{ k \in \mathbb{N} \mid x - y \in F_k \}$. As $2^{-n} = d(x,y) \leq 2^{-m}$ we have $m \leq n$, in particular $x - y \in F_n \subseteq F_m$. Letting $f := y - x \in F_m$ we get $y = x + f \in x + F_m$.

- Next we check, that d is a metric on G: Clearly $d(x,y) \geq 0$ for any $x, y \in G$, by construction. Also if $x = y$, then $d(x,y) = 0$. Conversely, if $x \neq y$ then $d(x,y) = 2^{-n} > 0$ for some $n \in \mathbb{N}$. Thus (M2) is satisfied, as well. Now to the symmetry: If $x = y$, then $d(x,y) = 0 = d(y,x)$ is clear. In case $x \neq y$ the equality $d(x,y) = 2^{-n}$ means $x - y \in F_n$ but $x - y \notin F_{n+1}$. But F_n and F_{n+1} are subgroups, so $x - y \in F_n$ is equivalent to $y - x \in F_n$. Likewise $x - y \notin F_{n+1}$ is equivalent to $y - x \notin F_{n+1}$. Thus we get $d(y,x) = 2^{-n} = d(x,y)$. It remains to prove the triangle inequality: Consider any $x, y, z \in G$. If $y = x$ then $d(x,z) = d(y,z) = d(x,y) + d(y,z)$, likewise $d(x,z) = d(x,y) = d(x,y) + d(y,z)$ in case $y = z$. So let us assume $y \notin \{ x, z \}$. Then we have $d(x,y) = 2^{-m}$ and $d(y,z) = 2^{-n}$ for some maximal $m, n \in \mathbb{N}$ with $x - y \in F_m$ and $y - z \in F_n$. Without loss of generality let $m \leq n$, else interchange x and z. Then we have $F_n \subseteq F_m$ and hence, as F_m is a subgroup, $x - z = (x - y) + (y - z) \in F_m$. In particular $d(x,y) \leq 2^{-m} < 2^{-m} + 2^{-n} = d(x,y) + d(y,z)$.

- The equivalence of the open sets is easy: (a) $\iff$ (b) is just the definition of an open set, in a metric space. And we have already seen $B_{1/2^n}(x) \subseteq x + F_n \subseteq B_r(x)$ for any $r > 1/2^n$ in the second item, above. Thus for (c) $\implies$ (b) choose $r := 1/2^n > 0$, then $B_r(x) \subseteq x + F_n(x) \subseteq U$. Conversely for (b) $\implies$ (c) simply choose some $n \in \mathbb{N}$ such that $2^{-n} < r$. Then $x + F_n \subseteq B_r(x) \subseteq U$ such that $x \in x + F_n \subseteq U$ is satisfied, as well.

- It only remains that $(G, \mathcal{T}, +)$ is a topological group. That is for any open set $U \subseteq G$ and any $x \in G$ we have to verify, that $x + U$, $U + x$ and $-U = \{ -u \mid u \in U \}$ are open again. As G is commutative we have $x + U = U + x$ and hence it suffices to check $x + U \subseteq G$ open. So consider any $y \in x + U$, that is $y - x \in U$. As U is open, property (c) asserts, that there is some $n \in \mathbb{N}$, such that $(y - x) + F_n \subseteq U$. Adding x to this equation we get $y + F_n \subseteq x + U$ and as this is true for any $y \in x + U$ we find, that $x + U$ is open, again. Likewise we start with any $y \in -U$, which is $-y \in U$. Again, as U is open, there is some $n \in \mathbb{N}$ such that $(-y) + F_n \subseteq U$. Taking inverses, we find $y - F_n = -((-y) + F_n) \subseteq -U$. But $-F_n = F_n$, as F_n is a subgroup, such that we get $y + F_n \subseteq -U$, which means that $-U$ is open, too.

□

Proof of (6.43):

- It is easy to see, that $\sim$ is an equivalence relation on $\text{Cauchy}(X, d)$: If $(x_n) \subseteq X$ is a Caucy-sequence then for any $\varepsilon > 0$ we find some $n(\varepsilon) \in \mathbb{N}$ such that (for any $m = n \geq n(\varepsilon)$) we get $d(x_n, x_n) < \varepsilon$ and this is $(x_n) \sim (x_n)$. The symmetry of $\sim$ is clear, as d is symmetric: If $(x_n) \sim (y_n)$ then $d(y_n, x_n) = d(x_n, y_n) < \varepsilon$, such that $(y_n) \sim (x_n)$, as well. And finally $\sim$ also is transitive: If $(x_n) \sim (y_n)$ and $(y_n) \sim (z_n)$ and $\varepsilon > 0$ is given, then we can choose $n(\varepsilon) \in \mathbb{N}$ such that $d(x_n, y_n) < \varepsilon/2$ and $d(y_n, z_n) < \varepsilon/2$ and thereby $d(x_n, z_n) \leq d(x_n, y_n) + d(y_n, z_n) < \varepsilon/2 + \varepsilon/2 = \varepsilon$ which means $(x_n) \sim (z_n)$ again.

- Let us first prove, that for any (x_n) and $(y_n) \in \text{Cauchy}(X, d)$ the sequence $(d_n) := (d(x_n, y_n)) \subseteq \mathbb{R}$ truly converges. As $\mathbb{R}$ is complete, it suffices to check, that (d_n) is a Cauchy-sequence. But (x_n) and (y_n) are, so given any $\varepsilon > 0$ we choose $n(\varepsilon) \in \mathbb{N}$, such that for any m, $n \geq n(\varepsilon)$ we have $d(x_m, x_n) < \varepsilon/2$ and $d(y_m, y_n) < \varepsilon/2$. Now let us compute

$$\begin{aligned} d(x_n, y_n) - d(x_m, y_m) &\leq d(x_n, x_m) + d(x_m, y_n) - d(x_m, y_m) \\ &\leq d(x_n, x_m) + d(x_m, y_m) + d(y_m, y_n) - d(x_m, y_m) \\ &= d(x_n, x_m) + d(x_m, y_n) \\ &< \varepsilon/2 + \varepsilon/2 \; = \; \varepsilon \end{aligned}$$

 Interchanging m and n, we find $-(d(x_n, y_n) - d(x_m, y_m)) = d(x_m, y_m) - d(x_n, y_n) < \varepsilon$, as well, such that $|d_n - d_m| = |d(x_n, y_n) - d(x_m, y_m)| < \varepsilon$. But this is the metric of $\mathbb{R}$, such that $(d_n) \subseteq \mathbb{R}$ is a Cauchy-sequence and hence convergent.

- In the next step, we will prove, that $\widehat{d}$ is well-defined: That is if $(x_n) \sim (x'_n)$ and $(y_n) \sim (y'_n)$ are Cauchy-sequences, then we have to check, that $d(x_n, y_n)$ and $d(x'_n, y'_n)$ converge to the same limit. And this can be done by proving that the difference converges to 0. So let's take a look: Given any $\varepsilon > 0$ we can choose $n(\varepsilon) \in \mathbb{N}$ in such a way that for any $n \geq n(\varepsilon)$ we get $d(x_n, x'_n) < \varepsilon/2$ and $d(y_n, y'_n) < \varepsilon/2$ and with this we may compute

$$\begin{aligned} d(x_n, y_n) - d(x'_n, y'_n) &\leq d(x_n, x'_n) + d(x'_n, y_n) - d(x'_n, y'_n) \\ &\leq d(x_n, x'_n) + d(x'_n, y'_n) + d(y'_n, y_n) - d(x'_n, y'_n) \\ &= d(x_n, x'_n) + d(y'_n, y_n) \end{aligned}$$

$$< \quad \varepsilon/2+\varepsilon/2 \;=\; \varepsilon$$

Interchanging x_n with x'_n and y_n with y'_n respectively, we also see $-(d(x_n,y_n)-d(x'_n,y'_n)) = d(x'_n,y'_n)-d(x_n,y_n) < \varepsilon$ and hence $|d(x_n,y_n)-d(x'_n,y'_n)| < \varepsilon$. As this is the metric of $\mathbb{R}$ we conclude $(d(x_n,y_n)-d(x'_n,y'_n)) \to 0$ which means that $(d(x_n,y_n))$ and $(d(x'_n,y'_n)) \subseteq \mathbb{R}$ converge to the same limit. And this means that $\widehat{d}$ is independent of the specific representative of $[x_n]$ resp. $[y_n]$ chosen.

- Let us now prove, that for any x, $y \in X$ we get $\widehat{d}([x],[y]) = d(x,y)$. That is $(d(x_n,y_n)) \to d(x,y)$. But by construction $x_n = x$ and $y_n = y$ for any $n \in \mathbb{N}$, such that $(d(x_n,y_n))$ is the constant sequence $(d(x,y))$. And for this it is clear, that it converges against $d(x,y)$.

- Let us check, that $\widehat{d}$ is a metric: First of all, as for any (x_n), $(y_n) \in \text{Cauchy}\,(X,d)$ and any $n \in \mathbb{N}$ we have $d_n := d(x_n,y_n) \geq$ the limit of $(d_n) \subseteq \mathbb{R}$ has to be positive, too. That is we always get $\widehat{d}([x_n],[y_n]) \geq 0$.

 Next we note that $\widehat{d}([x_n],[y_n]) = 0$ is equivalent to $(d(x_n,y_n)) \to 0$ which means that for any $\varepsilon > 0$ there is some $n(\varepsilon) \in \mathbb{N}$, such that $0 \geq d(x_n,y_n) < \varepsilon$. But this is precisely the definition of $(x_n) \sim (y_n)$ such that $[x_n] = [y_n]$. Thus $\widehat{d}$ also is definite.

 And clearly $\widehat{d}$ is symmetric, as d is symmetric. It only remains to verify the triangle inequality $\widehat{d}([x_n],[z_n]) \leq \widehat{d}([x_n],[y_n]) + \widehat{d}([y_n],[z_n])$. So look into the defining sequences, $\widehat{d}([x_n],[z_n])$ is the limit of $d(x_n,z_n)$ and by the triangle inequality of d we have $d(x_n,z_n) \leq d(x_n,y_n)+d(y_n,z_n)$. By taking $n \to \infty$ we find

$$\begin{aligned}\widehat{d}\big([x_n],[z_n]\big) \;&=\; \lim_{n\to\infty} d(x_n,z_n) \;\leq\; \lim_{n\to\infty}\big(d(x_n,y_n)+d(y_n,z_n)\big)\\ &=\; \lim_{n\to\infty} d(x_n,y_n) + \lim_{n\to\infty} d(y_n,z_n) \;=\; \widehat{d}\big([x_n],[y_n]\big)+\widehat{d}\big([y_n],[z_n]\big)\end{aligned}$$

- The next claim is that the natural map $\kappa : X \hookrightarrow \widehat{X} : x \mapsto [x]$ is injective: So consider any two x, $y \in X$ such that $[x] = [y]$. We have already seen, that this implies $0 = \widehat{d}([x],[y]) = d(x,y)$ such that we find $x = y$.

- But κ also is continuous, as both (X,d) and $(\widehat{X},\widehat{d})$ are metric spaces, we can use (6.6) by which it suffices to show, that for any $x \in X$ and $\varepsilon > 0$ there is some $\delta > 0$ such that $u \in B_\delta(X,x)$ implies $[u] \in B_\varepsilon(\widehat{X},[x])$. But we can just take $\delta := \varepsilon$ as thereby $\widehat{d}([u],[x]) = d(u,x) < \varepsilon$.

- Let us now prove that the completion $\widehat{X}$ is just that - complete. That is we are given a Cauchy-sequence $(s_m) \subseteq \widehat{X}$ and need to construct some $s \in \widehat{X}$ such that $(s_m) \to s$. As (s_m) is a Cauchy-sequence for any $\varepsilon > 0$ there is some $m(\varepsilon) \in \mathbb{N}$ such that for any m, $n \geq m(\varepsilon)$ we get $\widehat{d}(s_m,s_n) < \varepsilon/2$. And by construction any s_m is of the form $s_m = [x_{m,k}]$ for a Cauchy-sequence $(x_{m,k})$ (where the index runs over $k \in \mathbb{N}$). By definition of $\widehat{d}$ this is

$$\widehat{d}(s_m,s_n) \;=\; \lim_{k\to\infty} d\big(x_{m,k},x_{n,k}\big) \;<\; \frac{\varepsilon}{2}$$

 As $d(x_{m,k},x_{n,k})$ converges to $\widehat{d}(s_m,s_n)$ for any $\varepsilon > 0$ there is some $k(\varepsilon) \in \mathbb{N}$ such that for any

$k \geq k(\varepsilon)$ we get $|d(x_{m,k}, x_{n,k}) - \widehat{d}(s_m, s_n)| < \varepsilon/2$. Together this means

$$d(x_{m,k}, x_{n,k}) \;<\; \frac{\varepsilon}{2} + \widehat{d}(s_m, s_n) \;<\; \frac{\varepsilon}{2} + \frac{\varepsilon}{2} \;=\; \varepsilon$$

Now let $n(\varepsilon) := \max\{\, m(\varepsilon), k(\varepsilon) \,\}$ and for any $k \in \mathbb{N}$ we let $x_k := (x_{k,k})$ the diagonal elements of the s_k. Then, by the above, we have the following estimate for any m, $k \geq n(\varepsilon)$

$$d(x_{m,k}, x_k) \;=\; d(x_{m,k}, x_{k,k}) \;<\; \varepsilon$$

In particular, for any $m \geq n(\varepsilon)$ we see that the limit of $d(x_{m,k}, x_k)$ for $k \to \infty$ is ε at most. But the limit of this sequence is

$$\widehat{d}(s_m, s) \;=\; \lim_{k\to\infty} d(x_{m,k}, x_k) \;\leq\; \varepsilon$$

and as this is true for any $m \geq n(\varepsilon)$ we have found $(s_m) \to s$ for $m \to \infty$. In short: The diagonal sequence $(x_{k,k})$ yields the desired limit. And thereby $(x_{k,k})$ is a Cauchy-sequence in X, as for any j, $k \geq n(\varepsilon)$ we have seen $d(x_j, x_k) < \varepsilon$ before. That is the limit $s = [x_k] \in \widehat{X}$ is a well-defined point in the completion.

- In a final step we need to verify, that $\kappa(X)$ is a dense subset of $\widehat{X}$. But by (6.21.(v)) the closure of $\kappa(X)$ is given to be the set of limits of convergent sequences in $\kappa(X)$. So if we start with any $s := [x_n] \in \widehat{X}$ we need to find a sequence $(s_n) \in \kappa(X)$, such that $(s_n) \to s$. But this can be done in the following way: For any $n \in \mathbb{N}$ let $s_n := [x_n]$ for the *fixed* $x_n \in X$. As $(x_n) \subseteq X$ is a Cauchy-sequence we get: For any $\varepsilon > 0$ there is some $n(\varepsilon) \in \mathbb{N}$ such that for any m, $n \geq n(\varepsilon)$ we get $d(x_m, x_n) < \varepsilon/2$. Let us use this, to prove $(s_n) \to s$: The m-th coefficient of s_n is x_n, whereas the m-th coefficient of s is x_m. Thus $\widehat{d}(s_n, s)$ is the limit of $d(x_n, x_m)$ for $m \to \infty$. And by construction we have $d(x_n, x_m) < \varepsilon/2$ for any m, $n \geq n(\varepsilon)$. By taking to the limit $m \to \infty$ we find $\widehat{d}(s_n, s) \leq \varepsilon/2 < \varepsilon$ for any $n \geq n(\varepsilon)$. And this is precisely what we needed for $(s_n) \to s = [x_n]$. And as $[x_n] \in \widehat{X}$ was arbitrary, this means that $\widehat{X}$ is contained in the closure of $\kappa(X)$, such that the closure must be equal to $\widehat{X}$.

□

15.8 Proofs of Chapter 7

Proof of (7.2):
Throughout this proof we assume α, γ, $\varepsilon \in A$ and β, δ, $\eta \in B$. Suppose A and B are integral and $(\alpha,\beta)+(\varepsilon,\eta) = (\gamma,\delta)+(\varepsilon,\eta)$. By construction this means $\alpha+\varepsilon = \gamma+\varepsilon$ and $\beta+\eta = \delta+\eta$. But if A and B are integral this impliea $\alpha = \gamma$ and $\beta = \delta$ which is $(\alpha,\beta) = (\gamma,\delta)$ again. Hence in this case $A \times B$ is integral, too.
For any $\varepsilon \in A$ let us denote $S_A^{-1}(\varepsilon) := \{\, (\alpha,\gamma) \in A^2 \mid \alpha+\gamma = \varepsilon \,\}$ and likewise $S_B^{-1}(\eta)$ for some $\eta \in B$. Then $((\alpha,\beta),(\gamma,\delta)) \in S_{A\times B}^{-1}(\varepsilon,\eta)$ is equivalent to $(\alpha+\gamma,\beta+\delta) = (\varepsilon,\eta)$ which in turn is equivalent to $(\alpha,\gamma) \in S_A^{-1}(\varepsilon)$ and $(\beta,\delta) \in S_B^{-1}(\eta)$. That is we have a bijection of

$$\begin{array}{rcl} S_{A\times B}^{-1}(\varepsilon,\eta) & \longleftrightarrow & S_A^{-1}(\varepsilon) \times S_B^{-1}(\eta) \\ \big((\alpha,\beta),(\gamma,\delta)\big) & \mapsto & \big((\alpha,\gamma),(\beta,\delta)\big) \end{array}$$

If A and B are solution-finite, then both $S_A^{-1}(\varepsilon)$ and $S_B^{-1}(\eta)$ are finite and hence $S_A^{-1}(\varepsilon) \times S_B^{-1}(\eta)$ is finite, as well. But this means in this case $A \times B$ is solution-finite, too. □

Proof of (7.6):

(i) Recall the definition of the *minimum* and *maximum* of any two elements $\alpha,\beta \in A$ (this is truly well-defined, since $\leq$ is a linear order)

$$\alpha \wedge \beta \;:=\; \begin{cases} \alpha \text{ if } \alpha \leq \beta \\ \beta \text{ if } \beta \leq \alpha \end{cases} \qquad \alpha \vee \beta \;:=\; \begin{cases} \beta \text{ if } \alpha \leq \alpha \\ \beta \text{ if } \beta \leq \alpha \end{cases}$$

In the case that $M = \{\, \mu \,\}$ contains one element only, we clearly get the minimal and maximal elements $\mu_* = \mu = \mu^*$. If now M is given to be $M = \{\, \mu_1,\ldots,\mu_n \,\}$ where $n \geq 2$ then we regard

$$\begin{array}{rcl} \mu_* & := & (\ldots(\mu_1 \wedge \mu_2)\ldots) \wedge \mu_n \\ \mu^* & := & (\ldots(\mu_1 \vee \mu_2)\ldots) \vee \mu_n \end{array}$$

Then μ_* and μ^* are minimal, resp. maximal elements of M, which can be seen by induction on n: if $n = 2$ then μ_* is minimal by construction. Thus for $n \geq 3$ we let $H := \{\, \mu_1,\ldots,\mu_{n-1} \,\} \subseteq M$. By induction hypothesis we have $H_* = \{\, \nu_* \,\}$ for $\nu^* = ((\mu_1 \wedge \mu_2)\ldots) \wedge \mu_{n-1}$. Now let $\mu_* := \nu_* \wedge \mu_n$ then $\mu_* \leq \nu_* \leq \mu_i$ for $i < n$ and $\mu_* \leq \mu_n$ by construction. Hence we have $\mu_* \leq \mu_i$ for any $i \in 1\ldots n$, which means $\mu_* \in M_*$. And the uniqueness is obvious by the anti-symmetry of $\leq$. And this also proves the the claim for the maximal element μ^*, by taking to the inverse order $\alpha \geq \beta \;:\Longleftrightarrow\; \beta \leq \alpha$.

(ii) The existence of μ_* is precisely the property of a well-ordering. The uniqueness is immediate from the anti-symmetry of $\leq$ again: suppose μ_1 and μ_2 both are minimal elements of M, in particular $\mu_1 \leq \mu_2$ and $\mu_2 \leq \mu_1$. And this implies $\mu_1 = \mu_2$, as $\leq$ is a (linear) order on A.

(iii) In the direction (a) $\Longrightarrow$ (b) we consider $\alpha < \beta$. By the positivity of $\leq$ this implies $\alpha+\gamma \leq \beta+\gamma$. If the equality $\alpha+\gamma = \beta+\gamma$ would hold true then - as A is integral - we would find $\alpha = \beta$ in contradiction to the assumption $\alpha < \beta$. In the converse direction (b) $\Longrightarrow$ (a) we are given $\alpha \leq \beta$.

The positivity $\alpha + \gamma \leq \beta + \gamma$ (for any $\gamma \in A$) of $\leq$ is clear in this case. Now asume $\alpha + \gamma = \beta + \gamma$ then we need to show $\alpha = \beta$ to see that A is integral. But as $\leq$ is total we have $\alpha \leq \beta$ or $\beta \leq \alpha$, where we may assume $\alpha \leq \beta$ without loss of generality. If we now had $\alpha \neq \beta$ then $\alpha < \beta$ and hence $\alpha + \gamma < \beta + \gamma$ in contradiction to $\alpha + \gamma = \beta + \gamma$, which rests this case, too. Now (c) $\implies$ (b) is trivial such that there only remains the direction (b) $\implies$ (c). But this is clear - assume $\alpha + \gamma < \beta + \gamma$ but $\alpha \geq \beta$, then by the positivity (a) we would get the contradiction: $\alpha + \gamma \geq \beta + \gamma$.

(vii) We only need to show that $\geq$ is (strictly) positive again. That is we are given some α, α' and $\beta \in A$ such that $\alpha \geq \alpha'$ and we need to show $\alpha + \beta \geq \alpha' + \beta$. By definition this means $\alpha' \leq \alpha$. And as $\leq$ is (strictly) positive this implies $\alpha' + \beta \leq \alpha + \beta$ which again turns into $\alpha + \beta \geq \alpha' + \beta$. In the "strict" case all we have to do is replace "$\leq$" by "$<$" and likewise "$\geq$" by "$>$". Alternatively we could argue, that the integral property does not depend on the ordering chosen.

(iv) Assume $\mu \neq \mu_*$, then by minimality of μ_* this would yield $\mu_* < \mu$ and hence (by property (b) in item (iii) above) $\mu + \nu = \mu_* + \nu_* < \mu + \nu_*$. Thus we see that $\nu \neq \nu_*$ and hence (by minimality of ν_*) we get $\nu_* < \nu$ again. Using (b) once more this yields a contradiction

$$\mu + \nu \;<\; \mu + \nu_* \;<\; \mu + \nu$$

Thus we have seen that $\mu + \nu = \mu_* + \nu_*$ implies $\mu = \mu_*$ but in complete analogy we find that $\nu \neq \nu_*$ leads to another contradiction and hence $\nu = \nu_*$. The statement for maximal elements could be done in complete analogy to the minimal elements here. However it is even easier to regard the inverse order $\alpha \geq \beta$ which is a strictly positive order on A again, according to (vii). Under this order the maximal elements of $\geq$ are minimal elements of $\leq$. Hence the statement for maximal elements of $\leq$ turns into the statement for minimal elements of $\geq$. As as $\geq$ is a strictly positive, linear order on A again, this has been proved.

(viii) By assumption we have that for any $\gamma \in A$ the set $L_\gamma := \{\, \alpha \in A \mid \alpha \leq \gamma \,\}$ is finite. And we have to show that for any $\gamma \in A$ the set $A_\gamma := \{\, (\alpha, \beta) \in A^2 \mid \alpha + \beta = \gamma \,\}$ is finite, too. By assumption in particular the set L_0 is finite, thus we may take $\nu \in A$ to be the minimum of this set

$$\nu \;:=\; \min\{\, \alpha \in A \mid \alpha \leq 0 \,\}$$

This ν satisfies $\nu \leq \beta$ for any $\beta \in A$: If $\beta \leq 0$, then $\nu \leq \beta$ is just the minimality of ν. And if $\beta > 0$ then $\nu \leq 0 < \beta$ implies $\nu \leq \beta$, as well. Let us use this ν to define the following map

$$A_\beta \;\hookrightarrow\; L_\gamma \;:\; (\alpha, \beta) \mapsto \alpha$$

We first have to prove, that this map is well-defined: If we start with $(\alpha, \beta) \in A_\gamma$, then $\alpha + \beta = \gamma$. But we also have $\nu \leq \beta$ and by adding α this turns into $\alpha + \nu \leq \alpha + \beta = \gamma$ such that $\alpha + \nu \leq \gamma$ as desired. Next we will prove, that this map is injective: That is we start with any two (α, β) and (α', β') such that $\alpha + \beta = \alpha' + \beta'$ and $\alpha + \nu = \alpha' + \nu$. As A is integral, we get $\alpha = \alpha'$ from this. Thereby $\alpha + \beta = \gamma = \alpha + \beta'$ such that $\beta = \beta'$ as A still is integral. Altogether this is $(\alpha, \beta) = (\alpha', \beta')$ the injectivity of this map. Now that we have the injectivity, we conclude $\#A_\gamma \leq \#L_\gamma$ and in particular $\#A_\gamma$ is finite.

(ix) Let $A_0 := \{ (\alpha,\beta) \in A^2 \mid \alpha+\beta = 0 \}$. As A is solution finite we know, that A_0 is finite. Also let $A_+ := \{ \alpha \in A \mid \alpha > 0 \text{ and } \exists\, \beta \in A : \alpha+\beta = 0 \}$. Suppose there was some $\alpha \in A_+$. As A is integral the $\beta \in A$ for which $\alpha+\beta = 0$ is uniquely determined by α. Thus we would find an injective map of the form

$$A_+ \;\hookrightarrow\; A_0 \;:\; \alpha \mapsto (\alpha,\beta)$$

In particular we see that A_+ has to be a finite set. Choose $\mu := \min(A_+)$ the minimal element with this properties and let $\nu \in A$ be its partner $\mu+\nu = 0$. We will now prove that for any $n \geq 1$ we get (1) $n\mu \in A_+$ and (2) $n\mu + n\nu = 0$ and (3) $n\mu < (n+1)\mu$. Of course we will use induction on n and for $n = 1$ we have (1) and (2) by construction. As $\mu \in A_+$ we have $0 < \mu$ and thereby $\mu = 0+\mu < \mu+\mu = 2\mu$ which also is property (3). Now for the induction step: First of all we have $(n+1)\mu + (n+1)\nu = n\mu+\mu+n\nu+\nu = (n\mu+n\mu)+(\mu+\nu) = 0+0 = 0$, which is (2). And as $0 < \mu$ we get $n\mu = 0+n\mu < \mu+n\mu = (n+1)\mu$, which is (3). As $n\mu \in A_+$ by induction hypothesis we have $0 < n\mu$ and in combination with (3) also $0 < (n+1)\mu$. If we combine this with (2) we get $(n+1)\mu \in A_+$ again. Thus the induction is complete and we have found

$$0 \;<\; \mu \;<\; 2\mu \;<\; 3\mu \;<\; \ldots \;\in\; A_+$$

That is we have found infinitely many distinct elements in A_+ which contradicts A_+ being a finite set. The only way to evade this contradiction is by not mapping A_+ into A_0. And this only is the case if $A_+ = \emptyset$. That is there are *no* $\alpha \in A$ with $\alpha > 0$ and $\alpha+\beta = 0$ for some $\beta \in A$. But if $\alpha < 0$ and $\beta < 0$ then we get $\alpha+\beta < 0+\beta = \beta < 0$ such that $\alpha+\beta < 0$. In particular $\alpha+\beta \neq 0$ for all but $\alpha = 0 = \beta$.

□

Proof of (7.7):

- In the following we will regard arbitrary elements $\alpha = (\alpha_i)$, $\beta = (\beta_i)$ and $\gamma = (\gamma_i) \in A := \mathbb{N}^{\oplus I}$. In a first step we will show that - assuming $(I,\leq)$ is a linearly ordered set - the lexicographic order is a positive partial order on A. The *reflexivity* $\alpha \leq_{\text{lex}} \alpha$ is trivial, however, and for the *transitivity* we are given $\alpha \leq_{\text{lex}} \beta$ and $\beta \leq_{\text{lex}} \gamma$ and need to show $\alpha \leq_{\text{lex}} \gamma$. The case where two (or more) of α, β and γ are equal is trivial and hence the assumption $\alpha <_{\text{lex}} \beta <_{\text{lex}} \gamma$ reads as

$$\begin{aligned} \alpha_k < \beta_k \quad &\text{and} \quad \forall\, i < k \;:\; \alpha_i = \beta_i \\ \beta_l < \gamma_l \quad &\text{and} \quad \forall\, i < l \;:\; \beta_i = \gamma_i \end{aligned}$$

for some $k,l \in I$. We now let $m := \min\{k,l\}$ then it is easy to see, that $\forall\, i < m \;:\; \alpha_i = \beta_i = \gamma_i$ and $\alpha_m < \gamma_m$ which establishes $\alpha <_{\text{lex}} \gamma$. It remains to prove the *anti-symmetry*, i.e. we are given $\alpha \leq_{\text{lex}} \beta$ and $\beta \leq_{\text{lex}} \alpha$ and need to show $\alpha = \beta$. Suppose we had $\alpha \neq \beta$ then again

$$\begin{aligned} \alpha_k < \beta_k \quad &\text{and} \quad \forall\, i < k \;:\; \alpha_i = \beta_i \\ \beta_l < \alpha_l \quad &\text{and} \quad \forall\, i < l \;:\; \beta_i = \alpha_i \end{aligned}$$

In the case $k \leq l$ this implies $\alpha_k < \beta_k = \alpha_k$ and in the case $l \leq k$ we get $\beta_l < \alpha_l = \beta_l$. In both cases this is a contradiction. Hence $\leq_{\text{lex}}$ is a partial order, but the *strict positivity* is easy: Assume

$\alpha <_{\text{lex}} \beta$, then we need to show $\alpha + \gamma <_{\text{lex}} \beta + \gamma$. So by assumption there is some $k \in I$ such that

$$\alpha_k < \beta_k \quad \text{and} \quad \forall\, i < k \;:\; \alpha_i = \beta_i$$

But then $\alpha + \gamma <_{\text{lex}} \beta + \gamma$ is clear, as we can simply add $\gamma_k \in \mathbb{N}$ to $\alpha_k < \beta_k$ and add $\gamma_i \in \mathbb{N}$ to any $\alpha_i = \beta_i$ in the above property, from which we find

$$\alpha_k + \gamma_k < \beta_k + \gamma_k \quad \text{and} \quad \forall\, i < k \;:\; \alpha_i + \gamma_i = \beta_i + \gamma_i$$

- In a second step we will show that - assuming $(I, \leq)$ is a well-ordered set - the lexicographic order truly is a positive linear order on A. By the first step it only remains to verify that $\leq_{\text{lex}}$ is *total*, i.e. we assume that $\beta \leq_{\text{lex}} \alpha$ is untrue and need to show $\alpha \leq_{\text{lex}} \beta$. The assumption that $\beta \leq_{\text{lex}} \alpha$ is false means, that for any $k \in I$ we have

$$\beta_k \geq \alpha_k \quad \text{or} \quad \exists\, i < k \;:\; \alpha_i \neq \beta_i$$

It is clear that in particular $\alpha \neq \beta$ and therefore there is some $l \in I$ such that $\alpha_l \neq \beta_l$. Now, as $(I, \leq)$ is a well-ordered set, we may choose

$$k \;:=\; \min\{\, l \in I \mid \alpha_l \neq \beta_l \,\}$$

Then $\forall\, i < k$ we get $\alpha_i = \beta_i$ (as k was chosen minimally) and $\beta_k \geq \alpha_k$ (by assumption). Yet $\beta_k = \alpha_k$ is false by construction which only leaves $\beta_k > \alpha_k$ and hence establishes $\alpha \leq_{\text{lex}} \beta$.

- In the third step we assume that I is finite, i.e. $I = 1 \ldots n$ without loss of generality. Note that I clearly is well-ordered under its standard ordering and hence it only remains to prove the following assertion: let $\emptyset \neq M \subseteq A$ be a non-empty subset, then there is some $\mu \in M$ such that for any $\alpha \in M$ we get $\mu \leq_{\text{lex}} \alpha$. To do this we define

$$\begin{aligned}
\mu_1 &:= \min\{\, \alpha_1 \in \mathbb{N} \mid \alpha \in M \,\} \\
\mu_2 &:= \min\{\, \alpha_2 \in \mathbb{N} \mid \alpha \in M,\ \alpha_1 = \mu_1 \,\} \\
\ldots &\quad\ \ldots \\
\mu_n &:= \min\{\, \alpha_n \in \mathbb{N} \mid \alpha \in M,\ \alpha_1 = \mu_1, \ldots, \alpha_{n-1} = \mu_{n-1} \,\}
\end{aligned}$$

Hereby the set $\{\, \alpha_1 \mid \alpha \in M \,\}$ is non-empty, since $M \neq \emptyset$ was assumed to be non-empty. And $\{\, \alpha_2 \mid \alpha \in M, \alpha_1 = \mu_1 \,\}$ is non-empty, as there was some $\alpha \in M$ with $\alpha_1 = \mu_1$ and so forth. Hence μ is well defined and it is clear that $\mu \in M$, as $\mu = \alpha$ for some $\alpha \in M$. But the property $\mu \leq_{\text{lex}} \alpha$ is then clear from the construction.

- Now we will proof, that - assuming $(I, \leq)$ is a linearly ordered set - the ω-graded lexicographic order is a strictly positive partial order, as well. It is clear that $\leq_\omega$ inherits the property of being a partial order from $\leq_{\text{lex}}$ so it only remains to verify the strict positivity: Let $\alpha <_\omega \beta$, then we distinguish two cases. In the case $|\alpha|_\omega < |\beta|_\omega$ we clearly get

$$|\alpha + \gamma|_\omega \;=\; |\alpha|_\omega + |\gamma|_\omega \;<\; |\beta|_\omega + |\gamma|_\omega \;=\; |\beta + \gamma|_\omega$$

If on the other hand $|\alpha|_\omega = |\beta|_\omega$ then by assumption $\alpha <_{\text{lex}} \beta$ and as we have seen already this implies $\alpha + \gamma <_{\text{lex}} \beta + \gamma$. Thus in both cases we have found $\alpha + \gamma <_\omega \beta + \gamma$.

- We now assume that $(I, \leq)$ even is a well-ordered set and prove that $\leq_\omega$ is a total order in this case. Hence we need to regard the case that $\beta \leq_\omega \alpha$ is untrue. Of course this implies $|\alpha|_\omega \leq |\beta|_\omega$ and in the case $|\alpha|_\omega < |\beta|_\omega$ we are done already. Thus we may assume $|\alpha|_\omega = |\beta|_\omega$, but in this case the assumption reads as: $\neg\, \beta \leq_{\text{lex}} \alpha$. As we have seen above the lexicographic order is total and hence $\alpha <_{\text{lex}} \beta$ which conversely implies $\alpha <_\omega \beta$.

- In the final step we assume that I is finite, i.e. $I = 1 \ldots n$ and we need to show that $\leq_\omega$ is a well-ordering. Thus let $\emptyset \neq M \subseteq A$ be a non-empty subset again, then we have to verify that there is some $\mu \in M$ such that for any $\alpha \in M$ we get $\mu <_\omega \alpha$. To do this we define

$$\begin{aligned} m &:= \min\{\, |\alpha|_\omega \mid \alpha \in M \,\} \\ \mu &:= \min\{\, \alpha \mid \alpha \in M,\ |\alpha|_\omega = m \,\} \end{aligned}$$

 where the second minimum is taken under the lexicographic order. As M is non-empty m is well-defined and as $\leq_{\text{lex}}$ has been shown to be a well-ordering μ is well-defined, too. But $\mu \in M$ is trivial and $\mu \leq_\omega \alpha$ is clear from the construction.

□

15.9 Proofs of Chapter 8

Proof of (8.1):
In (i) we have to check that α truly is a homomorphism of rings. First of all we have $\varphi(1_R) = 1_R\,1_A = 1_A$ due to property (M.4) of the R-algebra A. Next we see $\varphi(a+b) = (a+b)1_A = (a\,1_A) + (b\,1_A) = \alpha(a) + \alpha(b)$ by property (M.2) of A. And lastly by properties (A) and (M.3) of A we also have

$$\begin{aligned}\varphi(a)\cdot\varphi(b) &= (a\,1_A)\cdot(b\,1_A) \;=\; a\,\big(1_A\dot{(}b\,1_A)\big)\\ &= a\,(b\,1_A) \;=\; (a\cdot b)\,1_A \;=\; \alpha(a\cdot b)\end{aligned}$$

Conversely for (ii) the properties (R) of an R-algebra are granted, as A has been assumed to be a ring. It remains to verify properties (M) and (A), as well. But these are straightforward, too:

$$\begin{aligned}a\,(s+t) &= \alpha(a)\cdot(s+t) \;=\; (\alpha(a)\cdot s) + (\alpha(a)\cdot t) \;=\; (a\,s) + (a\,t)\\ (a+b)\,s &= \alpha(a+b)\cdot s \;=\; \big(\alpha(a)+\alpha(b)\big)\cdot s\\ &= \big(\alpha(a)\cdot s\big) + \big(\alpha(b)\cdot s\big) \;=\; (a\,s) + (b\,s)\\ (a\cdot b)\,s &= \alpha(a\cdot b)\cdot s \;=\; \big(\alpha(a)\cdot\alpha(b)\big)\cdot s\\ &= \alpha(a)\cdot\big(\alpha(b)\cdot s\big) \;=\; a\,(b\,s)\\ 1_R\,s &= \alpha(1_R)\cdot s \;=\; 1_A\cdot s \;=\; s\\ (a\,s)\cdot t &= \big(\alpha(a)\cdot s\big)\cdot t \;=\; \alpha(a)\cdot\big(s\cdot t\big) \;=\; a\,(s\cdot t)\\ s\cdot(a\,t) &= s\cdot\big(\alpha(a)\cdot t\big) \;=\; \big(s\cdot\alpha(a)\big)\cdot t \;=\; \big(\alpha(a)\cdot s\big)\cdot t\\ &= \alpha(a)\cdot\big(s\cdot t\big) \;=\; a\,(s\cdot t)\end{aligned}$$

It remains to prove (iii): If S is R-torsion free we consider any a, $b \in R$ such that $a\,1_S = b\,1_S$. Then we have $(a-b)1_S = 0$, as $S \neq 0$ we have $1_S \neq 0_S$ and as S is torsion-free, this means $a = b$. But this already is the injectivity of α. Conversely if S is an integral domain and α is injective we consider any $a \in R$ and $s \in S$ such that $as = 0$. If $s = 0$ we are done, otherwise

$$0_R 1_S \;=\; 0_S \;=\; as \;=\; a(1_S\cdot s) \;=\; (a\,1_S)\cdot s$$

As $s \neq 0$ and S is an integral domain we conclude $a\,1_S = 0_S = 0_R 1_S$ and by the injectivity of α this is $a = 0$. That is we then find, that S truly is R-torsion-free. □

Proof of (8.2):

- Let us begin with (a) $\Longrightarrow$ (b): That is we need to show $as \in S$ for any $a \in R$ and any $s \in S$. Yet $S \;\leq_{\mathsf{r}}\; T$ is a sub-ring, in particular closed under multiplication and we have $as = a(1_T s) = (a1_T)s \in S$, as both $s \in S$ and $a1_T \in S$ by assumption (a).
- For (b) $\Longrightarrow$ (c) we note that $1_T \in S$ and S is closed under addition and multiplication, as $S \;\leq_{\mathsf{r}}\; T$ was assumed to be a sub-ring. And as we also have $as \in S$ for any $a \in R$ and $s \in S$, by assumption (b), we find $S \;\leq_{\mathsf{m}}\; T$. But a sub-module S with $1_T \in S$, that is closed under multiplication is a sub-algebra $S \;\leq_{\mathsf{a}}\; T$ of T.
- We have to close the circle, by proving (c) $\Longrightarrow$ (a): As $S \;\leq_{\mathsf{a}}\; T$ is a sub-algebra we have $1_T \in S$

and $as \in S$ for any $a \in R$ and $s \in S$. In particular $a1_T \in S$ for any $a \in R$, as S is closed under scalar-multiplication.

□

Proof of (8.4):

- We first want to show that for any $u_1, \ldots, u_n \in S$ the set $R[u_1, \ldots, u_n]$, defined explicitly as the set of all polynomial expressions $f(u_1, \ldots, u_n)$ where $f \in R[t_1, \ldots, t_n]$, is an R-algebra. To see this we note that in a ring extension $S : R$ both rings have been required to be commutative. Hence for any multi-indexes $\alpha = (\alpha_1, \ldots, \alpha_n)$ and $\beta = (\beta_1, \ldots, \beta_n) \in \mathbb{N}^n$ we find

$$u^{\alpha+\beta} \;=\; \prod_{k=1}^{n} u_k^{\alpha_k+\beta_k} \;=\; \prod_{k=1}^{n} u_k^{\alpha_k} \cdot u_k^{\beta_k} \;=\; \prod_{k=1}^{n} u_k^{\alpha_k} \cdot \prod_{k=1}^{n} u_k^{\beta_k} \;=\; u^{\alpha} \cdot u^{\beta}$$

 Thus the map $\sigma : \mathbb{N}^n \to S : \alpha \mapsto u^{\alpha}$ is a homomorphism of monoids. Also $\varphi : R \to S : a \mapsto a1_S$ is a homomorphism of rings, even of R-algebras. Therefore $\sigma_\varphi : R[t_1, \ldots, t_n] \to S : f \mapsto f(u_1, \ldots, u_n)$ is a homomorphism of rings, according to (7.14). But the property $\sigma_\varphi(af) = \varphi(a) \cdot \sigma_\varphi(f) = a1_S \cdot \sigma_\varphi(f) = a\sigma_\varphi(f)$ means that it even is a homomorphism of R-algebras.

 By construction we have $R[u_1, \ldots, u_n] = \mathrm{im}(\sigma_\varphi)$, such that this set is the image of an R-algebra homomorphism to S. In particular it is an R-algebra in itself - it is an R-module, according to (3.71) and a ring, according to (1.76).

- From here it is easy to see, that generally $R[U]$ is an R-algebra, as well. Given any two $x, y \in R[U]$ we find that $x \in R[u_1, \ldots, u_m]$ and $y \in R[v_1, \ldots, v_n]$ for some u_i and $v_j \in U$ respectively. But then both are contained in $R[u_1, \ldots, u_m, v_1, \ldots, v_n] \subseteq R[U]$. And hence the sum $x + y$ and product xy are contained in $R[u_1, \ldots, u_m, v_1, \ldots, v_n]$ and thereby in $R[U]$ again. Thus $R[U]$ is an R-algebra.

- As $R[U]$ is an R-algebra and clearly $U \subseteq R[U]$ we find the inclusion $\langle U \rangle_{\mathsf{a}} \subseteq R[U]$. Conversely consider any $Q \leq_{\mathsf{a}} S$ with $U \subseteq Q$. If now $x = f(u_1, \ldots, u_n) \in R[U]$ then any $u_k \in U \subseteq Q$ and hence $x \in Q$. Thus we have $R[U] \subseteq Q$ and as this is true for any such Q we also find $R[U] \subseteq \langle U \rangle_{\mathsf{a}}$.

□

Proof of (8.5):
If $S : R$ is a ring-extension and $u_1, \ldots, u_k \in S$ are elements of S, then by construction of polynomials $f \in R[t_1, \ldots, t_k]$ and the evaluation of f on the u_i, the elements of $R[u_1, \ldots, u_k]$ are of the form

$$f(u_1, \ldots, u_k) \;=\; \sum_{\alpha \in \mathbb{N}^k} f[\alpha]\, u_1^{\alpha_1} \ldots u_k^{\alpha_k}$$

Let us abbreviate the intermediate ring $A := R[u_1, \ldots, u_k]$ of $S : R$ for the time being. Then consequentially, if $u_{k+1}, \ldots, u_n \in S$ are another elements of S (not necessarily distinct from $u_1, \ldots, u_k$) then an element of $A[u_{k+1}, \ldots, u_n]$ is of the form

$$g(u_{k+1}, \ldots, u_n) \;=\; \sum_{\beta \in \mathbb{N}^{n-k}} g[\beta]\, u_{k+1}^{\beta_{k+1}} \ldots u_n^{\beta_n}$$

where $g[\beta] \in A = R[u_1, \ldots, u_k]$. That is every $g[\beta]$ is of the form above and inserting this into $g(u_{k+1}, \ldots, u_n)$ we find an element of S, of the form

$$\sum_{\beta \in \mathbb{N}^{n-k}} \sum_{\alpha \in \mathbb{N}^k} g[\beta][\alpha]\, u_1^{\alpha_1} \ldots u_k^{\alpha_k} u_{k+1}^{\beta_{k+1}} \ldots u_n^{\beta_n}$$

Letting $\gamma := (\alpha, \beta) \in \mathbb{N}^n$ we see, that this $g(u_{k+1}, \ldots, u_n)$ is an element of $R[u_1, \ldots, u_n]$, as it is of the form

$$g(u_{k+1}, \ldots, u_n) \;=\; \sum_{\gamma \in \mathbb{N}^n} g[\beta][\alpha]\, u_1^{\gamma_1} \ldots u_n^{\gamma_n}$$

So this is any $g(u_{k+1}, \ldots, u_n) \in R[u_1, \ldots, u_k][u_{k+1}, \ldots, u_n]$ also is an element of $R[u_k, \ldots, u_n]$ and hence the respective inclusion. Conversely it is clear, that any element of $h(u_1, \ldots, u_n) \in R[u_1, \ldots, u_n]$ can be rearranged in such a way, that we see that it also is an element of $R[u_1, \ldots, u_k][u_{k+1}, \ldots, u_n]$, as it can be written in the form

$$\sum_{\beta \in \mathbb{N}^{n-k}} \left(\sum_{\alpha \in \mathbb{N}^k} h[\alpha, \beta]\, u_1^{\alpha_1} \ldots u_k^{\alpha_k} \right) u_{k+1}^{\beta_{k+1}} \ldots u_n^{\beta_n}$$

That is we have see the following identity of intermediate rings of $S : R$ given arbitrary, but finitely many, elements $u_1, \ldots, u_n$ of S

$$R[u_1, \ldots, u_k][u_{k+1}, \ldots, u_n] \;=\; R[u_1, \ldots, u_n]$$

In other words, we have $R[U][V] = R[U \cup V]$ for any finite subsets U, $V \subseteq S$. However, if U, $V \subseteq S$ are arbitrary subsets of S, then any element $h \in R[U \cup V]$ is contained in some $R[U_0 \cup V_0]$ for some *finite* subsets $U_0 \subseteq U$ and $V_0 \subseteq V$. Thus we have seen $h \in R[U_0][V_0] \subseteq R[U][V]$ and hence $R[U \cup V] \subseteq R[U][V]$. Conversely if $g \in R[U][V]$ then $g \in R[U][V_0]$ for some finite subset $V_0 = \{ v_1, \ldots, v_n \} \subseteq V$. That is g is of the form

$$g \;=\; \sum_{\beta \in \mathbb{N}^n} g[\beta]\, v_1^{\beta_1} \ldots u_n^{\beta_n}$$

where only finitely many $g[\beta] \in R[U]$ are non-zero. For any such $g[\beta]$ there is a finite subset $U_\beta \subseteq U$ such that $g[\beta] \in R[U_\beta]$ (if $g[\beta] = 0$ we can take $U_\beta = \emptyset$). Now let

$$U_0 \;:=\; \bigcup_{\beta \in \mathbb{N}^n} U_\beta \;\subseteq\; U$$

By construction this is a finite subset of U and we have $g \in R[U_0][V_0]$ which is $g \in R[U_0 \cup V_0] \subseteq R[U \cup V]$ as we have seen above. That is we also have $R[U][V] \subseteq R[U \cup V]$ and hence the equality of these intermediate rings. □

Proof of (8.6):

- For (a) $\implies$ (b) it suffices to note that $S \leq_{\mathsf{a}} T$ is a sub-algebra of T, by assumption. Thus if also $U \subseteq S$, then the sub-algebra generated by U is contained in S, as well: $\langle U \rangle_{\mathsf{a}} \subseteq S$. But this is $R[U] = \langle U \rangle_{\mathsf{a}}$, already. The implication (b) $\implies$ (c) is trivial by taking $U := \{ u, v \}$.
- Finally for (c) $\implies$ (a): As 0_T and $1_T \in R[u, v]$ we also have 0_T and $1_T \in S$. Now consider any u, $v \in S$ and $a \in R$, then au, $u + v$ and $uv \in R[u, v] \subseteq S$. That is S is closed under scalar-multiplication, addition and multiplication, which means $S \leq_{\mathsf{a}} T$ is a sub-algebra and hence an

intermediate ring.

□

Proof of (8.7):

(i) Consider any $z \in T$, as Y generates T as an S-module there are some $y_1, \ldots, y_n \in Y$ and some $s_1, \ldots, s_n \in S$ such that

$$z = \sum_{j=1}^{n} s_j y_j$$

But S is generated by X, as an R-module, that is for any $j \in 1 \ldots n$ there are some $x_{1,j}, \ldots, x_{m(j),j} \in X$ and $a_{1,j}, \ldots, a_{m(j),j} \in R$ such that

$$s_j = \sum_{i=1}^{m(j)} a_{i,j} x_{i,j}$$

Combining these equations we find that z is an R-linear combination of elements of the form $x_{i,j} y_j \in XY$ and hence T is generated by XY, as an R-module

$$z = \sum_{j=1}^{n} \sum_{i=1}^{m(j)} a_{i,j} x_{i,j} y_j$$

(ii) Consider some $a_1, \ldots, a_n \in R$ and some pairwise distinct $z_1, \ldots, z_n \in XY$ (that is $z_k = x_k y_k$ for some $x_k \in X$ and $y_k \in Y$) such that

$$\sum_{k=1}^{n} a_k z_k = 0$$

Renumbering we may assume w.l.o.g. that $y_1, \ldots, y_m$ is a collection of distinct elements of $\{ y_1, \ldots, y_n \}$ and for any $i \in 1 \ldots m$ we denote $K_i := \{ k \in 1 \ldots n \mid y_k = y_i \}$. That is $\{ K_1, \ldots, K_m \}$ is a partition of $1 \ldots n$. Then we find that

$$0 = \sum_{k=1}^{n} a_k z_k = \sum_{i=1}^{m} \left(\sum_{k \in K_i} a_k x_k \right) y_i$$

As Y is S-linearly independent and the y_i are pairwise distinct we conclude that for any $i \in 1 \ldots m$ we necessarily have

$$0 = \sum_{k \in K_i} a_k x_k$$

For any $i \in 1 \ldots m$ and any two indices $p \neq q \in K_i$ the elements x_p and x_q are distinct $x_p \neq x_q$, as else $z_p = x_p y_i = x_q y_i = z_q$ in contradiction to the pairwise distinctness of the z_k. Yet as X is R-linearly independent we conclude that for any $k \in K_i$ we must have $a_k = 0$. And as any $k \in 1 \ldots n$ is contained in one of the K_i we have $a_k = 0$ for any $k \in 1 \ldots n$.

(iii) A basis is a linearly independent set, that generated a s a module. Thus this statement is an immediate consequence of (i) and (ii) combined.

(iv) Let $X \subseteq S$ be a set of generators of S as an R-module, of minimal cardinality, that is $|X| = [S : R]$. Likewise pick up $Y \{ T \}$ such that $|Y| = [T : S]$. By (i) we know that XY generates T as an R-module and hence $[T : R] \leq |XY|$. But clearly $X \times Y \twoheadrightarrow XY : (x, y) \mapsto xy$ is a surjective map

and hence $|XY| \leq |X \times Y| = |X| \cdot |Y|$. Thus we have the chain of inequalities

$$[T:R] \;\leq\; |XY| \;\leq\; |X \times Y| \;=\; |X| \cdot |Y| \;=\; [S:R] \cdot [T:S]$$

Which proves the first part. If now R and S are fields, then we may even choose an R-basis $X \subseteq S$ of S and an S-basis $Y \subseteq T$ of T. By (iii) XY then is an R-basis of T and hence we have $[T:R] = |XY|$. Yet, as XY is R-linearly independent the elements $xy \in XY$ also have to be pairwise distinct. That is the map $X \times Y \longleftrightarrow XY : (x,y) \mapsto xy$ is bijective, in this case. And therefore all the above inequalities turn into equalities

$$[T:R] \;=\; |XY| \;=\; |X \times Y| \;=\; |X| \cdot |Y| \;=\; [S:R] \cdot [T:S]$$

□

Proof of (8.10):

(i) Let us denote $x := t + fR[t]$ and $\mathcal{M} := \{\, x^k \mid 0 \leq k < n \,\}$. We will first prove that $\mathcal{M}$ is a generating set of S as an R-module: If $g \in R[t]$ is any polynomial, then we may use division with remainder (as f is monic) to find some $q, r \in R[t]$ such that

$$g \;=\; qf + r$$

and $r = 0$ or $\deg(r) < n$. Thereby $g + fR[t] = qf + r + fR[t] = r + fR[t]$ and as $\deg(r) < n$ this means $g + fR[t] = r[0]x^0 + r[1]x^1 + \cdots + r[n-1]x^{n-1}$ such that $g + fR[t]$ can be generated as an R-linear combination over $\mathcal{M}$. As g has been arbitrary this is

$$S \;=\; \mathrm{Lh}\{\, x^0, x^1, \ldots, x^{n-1} \,\} \;=\; \Big\{\, t^k + fR[t] \mid 0 \leq k < n \,\Big\}$$

To complete that $\mathcal{M}$ is an R-basis of S, as an R-module, we have to prove the linear independence of $\mathcal{M}$: Suppose there were some $a_0, a_1, \ldots, a_{n-1} \in R$ satisfying a relation of the form

$$\sum_{k=0}^{n-1} a_k x^k \;=\; \sum_{k=0}^{n-1} a_k t^k + fR[t] \;=\; 0 + fR[t]$$

That is $r(t) := a_0 t^0 + a_1 t^1 + \cdots + a_{n-1} t^{n-1} \in fR[t]$ such that $r = fg$ for some polynomial $g \in R[t]$. Suppose we had $g \neq 0$, as f is monic the leading coefficients of g and f cannot cancel each other, such that $\deg(r) = \deg(fg) = \deg(f) + \deg(g) \geq \deg(f) = n$ - refer to (7.18) for more details on this. However $\deg(r) \leq n - 1 < n$. This contradiction yields $g = 0$ and hence $r = 0$. But this again is $a_k = 0$ for any $k \in 0 \ldots (n-1)$ and hence $\mathcal{M}$ is linearly independent.

In particular: As $n \geq 1$ we find that $\{\, x \,\}$ is R-linearly independent. Hence suppose $\alpha(a) = \alpha(b)$ for some $a, b \in R$. Then $ax = bx$ such that $(a-b)x = 0 + fR[t]$. As we have seen above, this implies $a - b = 0$ and hence $a = b$, such that α is injective.

(ii) As $\deg(f) \geq 1$ there is some $k \in \mathbb{N}$ such that $f[k] \neq 0$. In particular $R \neq 0$ is not the zero-ring. Let us now use induction on n: In case $n = 1$, as f is monic, it is of the form $f(t) = t + f[0]$. That is we may take $S = R$ and $s_1 := -f[0]$ and are already done.

For the induction step we consider $\deg(f) = n$ and may assume the claim for any polynomial $q \in R[t]$ of degree $\deg(q) < n$. So we start out with

$$S_1 \;:=\; R[t_1] \Big/ f(t_1)R[t_1]$$

Again we abbreviate $x := t_1 + f(t_1)R[t_1]$ then we have seen in (i), that $S_1 : R$ is a ring extension under $\alpha : R \hookrightarrow S : a \mapsto ax^0$ and that $[S_1 : R] = n$. Also, as $g \mapsto g + f(t_1)R[t_1]$ is a homomorphism of R-algebras, we find that

$$f(x) \;=\; f\Big(t_1 + f(t_1)R[t_1]\Big) \;=\; f(t_1) + f(t_1)R[t_1] \;=\; 0 + f(t_1)R[t_1]$$

That is $f(x) = 0 \in S_1$ and hence $(t - x)$ divides f in $S_1[t]$, according to (7.54.(iii)). That is there is some $q \in S_1[t]$ such that $f(t) = q(t)(t - x)$. And as f is monic, (7.54.(i)) tells us, that q thereby is a monic polynomial of degree $n - 1$. Hence we may use the induction hypothesis on q to find another ring extension $S : S_1$ under $\beta : S_1 \hookrightarrow S$ such that $[S : S_1] \leq (n-1)!$ and q splits over S. That is

$$q(t) \;=\; (t - s_2) \dots (t - s_n)$$

for some sufficient $s_k \in S$. Let $s_1 := \beta(x) \in S$. By definition of the scalar multiplication of S we have $xq = \beta(x) \cdot q = s_1 q$ such that $f = (t - x)q = tq - xq = tq - s_1 q = (t - s_1)q$. Replacing q with its factorisation again, we have proved property (3)

$$f(t) \;=\; (t - s_1)(t - s_2) \dots (t - s_n)$$

Also property (1) is a given: Just take $S : R$ under the monomorphism $\beta\alpha : R \hookrightarrow S$. We have $[S_1 : R] = n$ by (i) and $[S : S_1] \leq (n-1)!$ by induction hypothesis. Now use the degree-formula (8.7.(iv)) to also find property (2)

$$[S : R] \;\leq\; [S : S_1] \cdot [S_1 : R] \;\leq\; (n-1)! \cdot n \;=\; n$$

(iii) Obviously we use induction on the number r of polynomials given. The case $r = 1$ has already been dealt with in (ii) so we continue with the induction step right away: By (ii) there is a ring extension $\alpha : R \to S_1$ such that f_1 splits over S_1. That is there are elements $x_j \in S$ such that

$$f_1(t) \;=\; \prod_{j=1}^{n(1)} (t - x_j)$$

Note that $[S_1 : R] \leq n_1! < \infty$ is finite. And as we have to compare these polynomials in $S_1[t]$, on a formal, set-theoretic basis, this identity reads as

$$\alpha(f_1)(t) \;=\; \prod_{j=1}^{n(1)} (t - x_j)$$

Let us now consider $\alpha(f_i) \in S_1[t]$ in the sense of (7.12.(iv)) for any $i \in 2 \dots r$. Now, by induction hypothesis, there is another ring extension $\beta : S_1 \hookrightarrow S$ such that all the $\alpha(f_i)$ split simultaneously.

That is there are elements $s_{i,j} \in S$ (where $i \in 2 \dots r$ and $j \in 1 \dots n(i)$) such that

$$\alpha(f_i)(t) \;=\; \prod_{j=1}^{n(i)} (t - s_{i,j})$$

By definition these identities compare the coefficients $\beta\alpha(f_i[k])$ of the left-hand side, with the coefficients of the right-hand side. But if we consider $f_i \in R[t]$ and the ring extension $S : R$ under $\beta\alpha : R \hookrightarrow S$, then the same is true for the identities

$$f_i(t) \;=\; \prod_{j=1}^{n(i)} (t - s_{i,j})$$

That is the $f_i \in R[t]$ for $i \in 2 \dots r$ split over S. Let us denote $s_{1,j} := \beta(x_j) \in S$, as f_1 splits over S_1 and $S : S_1$ is an extension of S_1 (8.9) tells us, that f_1 also splits over S in the just the same form

$$f_1(t) \;=\; \prod_{j=1}^{n(1)} (t - s_{1,j})$$

Thus if we take $\beta\alpha : R \hookrightarrow S$ as a ring extension, properties (1) and (3) are already satisfied. Now recall that by induction hypothesis we have $[S : S_1] < \infty$, as well. Thus the degree formula (8.7.(iv)) grants property (2) again, as we get

$$[S : R] \;\leq\; [S : S_1] \cdot [S_1 : R] \;<\; \infty$$

(iv) Let us first consider the case of a monic polynomial $f \in E[t]$, where E is a field. In this case $E[t]$ is an euclidean domain and hence an UFD such that we can modify the construction in (i) a little: We can choose a monic prime factor p of f, that is p is irreducible and $f = pg$ for some $g \in E[t]$. Then we have $1 \leq \deg(p) \leq \deg(f)$ and let $F := E[t]/pE[t]$. By (i) above $\alpha : E \hookrightarrow F$ is a finite ring of degree $[F : E] = \deg(p)$. And for $x := t + pE[t]$ we get $f(x) = p(x)g(x) = pg + pE[t] = 0$ again. As $pE[t]$ is a prime ideal and $p \neq 0$ we know by (2.79.(i)) that $pE[t]$ is a maximal ideal and hence $F = E[t]/pE[t]$ is a field. Thus we find a field F, such that $[F : E] \leq \deg(f)$ is finite and $f(x) = 0$ for some $x \in F$.

As in (ii) this process can be used inductively: Pick up a monic prime factor p_1 of f. Then by the above $F_1 := E[t_1]/p_1(t_1)E[t_1]$ is a field, $F_1 : E$ is a field extension of degree $[F_1 : E] \leq \deg(f)$ and $f = p_1 q_1$. Consider $q_1 \in F_1[t]$, then by induction hypothesis there is a field extension $[F : F_1]$ such that q_1 splits in F and $[F : F_1] \leq \deg(q_1)$. Then f splits over F, as in (ii).

Now for a general polynomial $f \in E[t]$ of $n = \deg(f) \geq 1$, where E is a field. In this case we let $a := \mathrm{lc}(f) \in E$. As $a \neq 0$ we have $a \in E^*$ and thereby $m := a^{-1}f$ is a monic polynomial of degree $\deg(m) = \deg(f)$. For this we have just seen, that there is a field F, such that $E \hookrightarrow F$ is a ring extension with $[F : E] \leq \deg(m)! = \deg(f)!$ and m splits over F. That is there are some $x_1, \dots, x_n \in F$ such that m and with it f can be written in the following form

$$f(t) \;=\; am(t) \;=\; a\prod_{i=1}^{n}(t - x_i)$$

□

Proof of (8.14):
As $A \subseteq \mathfrak{a}$ we have $\alpha(A) \subseteq \alpha(\mathfrak{a}) \subseteq \mathfrak{a}S$ such that $\langle \alpha(A) \rangle_{\mathfrak{i}} \subseteq \mathfrak{a}S$ is clear. For the converse inclusion we start with some $f \in \mathfrak{a}S$, that is there are some $s_k \in S$ and $b_k \in \mathfrak{a}$ such that

$$f \;=\; s_1 \cdot \alpha(b_1) + \cdots + s_n \cdot \alpha(b_n)$$

But as $\mathfrak{a}$ is generated by A, for any $k \in 1 \ldots n$ there are some $r_{i,k} \in R$ and $a_{i,k} \in A$ such that all the b_k are of the form

$$b_k \;=\; \sum_{i=1}^{m(k)} r_{i,k} a_{i,k}$$

Combining these equations we find that $f \in \langle \alpha(A) \rangle_{\mathfrak{i}}$, as well, since any $\alpha(a_{i,k}) \in \alpha(A)$ such that f is just an S-linear combination of elements of $\alpha(A)$:

$$f \;=\; \sum_{k=1}^{n} s_k \alpha(b_k) \;=\; \sum_{k=1}^{n} s_k \sum_{i=1}^{m(k)} \alpha(r_{i,k}) \alpha(a_{i,k}) \;=\; \sum_{k=1}^{n} \sum_{i=1}^{m(k)} s_k \alpha(r_{i,k}) \alpha(a_{i,k})$$

□

Proof of (8.15):
Given the structural homomorphism $\alpha : R \to S$ and an ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ we have defined the ideal $\mathfrak{a}S$ to be $\mathfrak{a}\,S = \langle \alpha(a) \mid a \in \mathfrak{a} \rangle_{\mathfrak{i}}$. In particular we have $\alpha(\mathfrak{a}) \subseteq \mathfrak{a}S$ and therefore $\mathfrak{a} \subseteq \mathfrak{b}$ implies $\alpha(\mathfrak{a}) \subseteq \alpha(\mathfrak{b}) \subseteq \mathfrak{b}\,S$, such that $\mathfrak{a}\,S \subseteq \mathfrak{b}\,S$ again. And for an ideal $\mathfrak{u} \trianglelefteq_{\mathfrak{i}} S$ we have defined $\mathfrak{u} \cap R = \alpha^{-1}(\mathfrak{u})$. In particular $\mathfrak{u} \subseteq \mathfrak{v}$ implies $\mathfrak{u} \cap R = \alpha^{-1}(\mathfrak{u}) = \alpha^{-1}(\mathfrak{v}) = \mathfrak{v} \cap R$. Now (0.7) yields

$$\mathfrak{a} \;\subseteq\; \alpha^{-1}\big(\alpha(\mathfrak{a})\big) \;\subseteq\; \alpha^{-1}\big(\mathfrak{a}\,S\big) \;=\; \big(\mathfrak{a}\,S\big) \cap R$$

And if $\mathfrak{u} \trianglelefteq_{\mathfrak{i}} S$ is an ideal in S then by definition any $x \in (\mathfrak{u} \cap R)S$ is of the form $x = s_1\alpha(a_1) + \cdots + s_n\alpha(a_n)$ where $s_k \in S$ and $a_k \in \mathfrak{u} \cap R$. But the latter is $\alpha(a_k) \in \mathfrak{u}$ and as $\mathfrak{u}$ is an ideal this means $x \in \mathfrak{u}$ again. As x has been arbitrary, this is the inclusion we aimed for

$$\big(\mathfrak{u} \cap R\big)\,S \;\subseteq\; \mathfrak{u}$$

Altogether we have proved property (b) of a covariant Galois-connection. Now by (0.24) this implies the identities for ideals of the form $\mathfrak{a}\,S \trianglelefteq_{\mathfrak{i}} S$ and $\mathfrak{u} \cap R \trianglelefteq_{\mathfrak{i}} R$ respectively. Also we find the 1-to-1 correspondence between ideals of this kind. In particular we have $(\mathfrak{a}\,S) \cap R = \mathfrak{a}$ for any $\mathfrak{a} = \mathfrak{u} \cap R$. And this already is the implication (b) $\implies$ (a) for prime ideals. In the converse direction (a) $\implies$ (b) we have $\mathfrak{p} = (\mathfrak{p}\,S) \cap R$ and need to find some $\mathfrak{q}$ such that $\mathfrak{p} = \mathfrak{q} \cap R$. To find this note that $U := R \setminus \mathfrak{p}$ is multiplicatively closed and hence $\alpha(U) \subseteq S$ is multiplicatively closed, too. We now argue, that

$$\alpha(U) \cap \mathfrak{p}\,S \;=\; \emptyset$$

Suppose there was some $a \in U$ with $\alpha(a) \in \mathfrak{p}\,S$, then this would mean $a \in \alpha^{-1}(\mathfrak{p}\,S) = (\mathfrak{p}\,S) \cap R = \mathfrak{p}$. But by construction of U this is absurd. We now denote $S_{\mathfrak{p}} := \alpha(U)^{-1}S$ and let $\mathfrak{u} := (\mathfrak{p}\,S)\,S_{\mathfrak{p}} \trianglelefteq_{\mathfrak{i}} S_{\mathfrak{p}}$ be the ideal $\mathfrak{p}\,S$ pushed further to $S_{\mathfrak{p}}$. Suppose we had $\mathfrak{u} = S_{\mathfrak{p}}$, then $1 \in \mathfrak{u}$, where 1 in $S_{\mathfrak{p}}$ is $1_S/1_S$. By

construction of $\mathfrak{u}$ this would mean that there would be some $s_1,\ldots,s_n \in S$, $u_1,\ldots,u_n \in U$ and some $q_1,\ldots,q_n \in \mathfrak{p}S$ such that

$$\frac{1_S}{1_S} \;=\; \frac{s_1}{\alpha(u_1)}\cdot\frac{q_1}{1_S}+\cdots+\frac{s_n}{\alpha(u_n)}\cdot\frac{q_n}{1_S} \;=\; \frac{t_1q_1+\cdots+t_nq_n}{\alpha(u_1)\ldots\alpha(u_n)}$$

where $t_1 := s_1\alpha(u_2)\cdot\cdots\cdot\alpha(u_n)$ and so on, until $t_n := s_n\alpha(u_1)\cdot\cdots\cdot\alpha(u_{n-1})$. As $\mathfrak{p}S \trianglelefteq_{\mathrm{i}} S$ is an ideal $q := t_1q_1+\cdots+t_nq_n \in \mathfrak{p}S$ and using $u := u_1\cdot\cdots\cdot u_n$ the equation above turns into $\alpha(v)\alpha(u) = \alpha(v)q \in \mathfrak{p}S$ for some $v \in U$. But $\alpha(uv) \in \mathfrak{p}S$ cannot be, as $\alpha(U)\cap\mathfrak{p}S = \emptyset$ and hence we get

$$\mathfrak{u} \;:=\; (\mathfrak{p}\,S)\,S_{\mathfrak{p}} \;\neq\; S_{\mathfrak{p}}$$

And thereby there is a maximal ideal $\mathfrak{n} \trianglelefteq_{\mathrm{i}} S_{\mathfrak{p}}$ that contains $\mathfrak{u} \subseteq \mathfrak{n}$. And for this ideal we then find the following chain of inclusions

$$\mathfrak{p}\,S \;\subseteq\; (\mathfrak{p}\,S_{\mathfrak{p}})\cap S \;\subseteq\; \mathfrak{u}\cap S \;\subseteq\; \mathfrak{n}\cap S$$

In the end we have $\mathfrak{p}\,S \subseteq \mathfrak{n}\cap S$. Let us denote $\mathfrak{q} := \mathfrak{n}\cap S$. We will see that this is the proper candidate for (a). To do this, as a next step, we claim

$$\mathfrak{q}\cap\alpha(U) \;=\; \emptyset$$

Suppose there was some $a \in U$ with $\alpha(a) \in \mathfrak{q}$. This would mean $\alpha(a)/1_S \in \mathfrak{n}$ and as $\mathfrak{a}(a)/1_S$ is a unit in $S_{\mathfrak{p}}$ this would imply $\mathfrak{n} = S_{\mathfrak{p}}$. But as $\mathfrak{n}$ is a maximal ideal this is not the case. We can now use the assumption on $\mathfrak{p}$ and the inclusion $\mathfrak{p}\,S \subseteq \mathfrak{q}$ to find another inclusion

$$\mathfrak{p} \;=\; (\mathfrak{p}\,S)\cap R \;\subseteq\; \mathfrak{q}\cap R$$

But as $\mathfrak{q}\cap\alpha(U) = \emptyset$ we also have $\emptyset = \alpha^{-1}(\mathfrak{q})\cap\alpha^{-1}(\alpha(U)) \supseteq (\mathfrak{q}\cap R)\cap U$. This can be reformulated, as $\mathfrak{q} \subseteq R\setminus U = \mathfrak{p}$ (by construction of U). Thus we also have the converse inclusion

$$\mathfrak{q}\cap R \;\subseteq\; \mathfrak{p}$$

Together $\mathfrak{p} \subseteq \mathfrak{q}\cap R$ and $\mathfrak{q}\cap R \subseteq \mathfrak{p}$ yield property (a) $\mathfrak{p} = \mathfrak{q}\cap R$ which had to be derived from (b). □

Proof of (8.17):

(i) By definition of the scalar multiplication in $S : R$ we have $as = \iota(a)\cdot s$. And as π is a homomorphism of rings, this turns into

$$\pi\big(as\big) \;=\; \pi\big(\iota(a)\cdot s\big) \;=\; \pi\iota(a)\cdot\pi(s) \;=\; a\cdot\pi(s)$$

(ii) By definition $\pi^{-1}(\mathfrak{a}) = \{\, s\in S \mid \pi(s)\in\mathfrak{a}\,\}$ and the ideal $\mathfrak{a}S$ is generated by $\iota(\mathfrak{a}) = \{\,\iota(a)\mid a\in\mathfrak{a}\,\}$. Thus if we start with $s = \iota(a) \in \iota(\mathfrak{a})$, then we have $\pi(s) = \pi\iota(a) = a \in \mathfrak{a}$, such that $s \in \pi^{-1}(\mathfrak{a})$. Hence we have $\iota(\mathfrak{a}) \subseteq \pi^{-1}(\mathfrak{a})$, but as the letter is an ideal, the same is true for the ideal generated by this set $\mathfrak{a}S \subseteq \pi^{-1}(\mathfrak{a})$.

(iii) This is trivial, if we just look at the definition $\mathfrak{u}\cap R = \iota^{-1}(\mathfrak{u}) = \{\, a\in R \mid \iota(a)\in\mathfrak{u}\,\}$. If we start

with some $a \in R$ such that $\iota(a) \in \mathfrak{u}$, then $a = \pi\iota(a) \in \pi(\mathfrak{u})$ such that $\mathfrak{u} \cap R \subseteq \pi(\mathfrak{u})$.

□

Proof of (8.18):
By definition of the pull-back we have $(\mathfrak{c} \cap S) \cap R = \alpha^{-1}(\mathfrak{c} \cap S) = \alpha^{-1}(\beta^{-1}(\mathfrak{c})) = (\beta\alpha)^{-1}(\mathfrak{c}) = \mathfrak{c} \cap R$. Thus the second identity is done already. For the first let us begin with the inclusion $\mathfrak{a}T \subseteq (\mathfrak{a}S)T$: Given any $g \in \mathfrak{a}T$ there are some $t_1, \ldots, t_n \in T$ and $a_1, \ldots, a_n \in \mathfrak{a}$ such that $g = t_1\beta\alpha(a_1) + \cdots + t_n\beta\alpha(a_n)$. With $f_i := \alpha(a_i) \in \mathfrak{a}S$ this means $g = t_1\beta(f_1) + \cdots + t_n\beta(f_n)$ and hence $g \in (\mathfrak{a}S)T$.
Now for $(\mathfrak{a}S)T \subseteq \mathfrak{a}T$ we start with some g of the form $g = t_1\beta(f_1) + \cdots + t_n\beta(f_n)$, where $t_k \in T$ and $f_k \in \mathfrak{a}S$. That is the f_k are of the form $f_k = s_{1,k}\alpha(a_{1,k}) + \cdots + s_{m(k),k}\alpha(a_{m(k),k})$ where $s_{i,k} \in S$ and $a_{i,k} \in \mathfrak{a}$. Combining these we find $g \in \mathfrak{a}T$, as

$$g \;=\; \sum_{k=1}^{n} t_k\beta(f_k) \;=\; \sum_{k=1}^{n}\sum_{i=1}^{m(k)} t_k\beta(s_{i,k}) \cdot \beta\alpha(a_{i,k}) \;\in\; \mathfrak{a}T$$

□

Proof of (8.19):

(i) We prove the well-definedness and injectivity of $a + \mathfrak{a} \mapsto \alpha(a) + \mathfrak{u}$ at the same time: Consider any $a, b \in R$ with $a + \mathfrak{a} = b + \mathfrak{a}$, this is equivalent, to $b - a \in \mathfrak{a} = \mathfrak{u} \cap R = \alpha^{-1}(\mathfrak{u})$. And this is just a reformulation of $\alpha(b - a) \in \mathfrak{u}$. Now, as α is a homomorphism this again is equivalent, to $\alpha(a) + \mathfrak{u} = \alpha(b) + \mathfrak{u}$ so altogether we have

$$a + \mathfrak{a} \;= b + \mathfrak{a} \quad\Longleftrightarrow\quad \alpha(a) + \mathfrak{u} \;= \alpha(b) + \mathfrak{u}$$

In this equivalence $\Longrightarrow$ is the well-definedness and $\Longleftarrow$ is the injectivity of the map. So we are done in case of $\mathfrak{a} = \mathfrak{u} \cap R$.

(ii) Again consider $a, b \in R$ such that $a + \mathfrak{a} = b + \mathfrak{a}$. Again this is $b - a \in \mathfrak{a}$ and hence $\alpha(b - a) \in \alpha(\mathfrak{a}) \subseteq \mathfrak{a}S = \mathfrak{u}$. Thus we have $\alpha(a) + \mathfrak{u} = \alpha(b) + \mathfrak{u}$ which means $a + \mathfrak{a} \mapsto \alpha(a) + \mathfrak{u}$ is well-defined. Now suppose $\mathfrak{a} = (\mathfrak{a}S) \cap R = \mathfrak{u} \cap R$ then we also need to show the injectivity: If $\alpha(a) + \mathfrak{u} = \alpha(b) + \mathfrak{u}$ then we get $b - a \in \mathfrak{u} \cap R$ as in (i) before. Thus we have $b - a \in \mathfrak{a}$ by assumption on $\mathfrak{a}$ and hence $a + \mathfrak{a} = b + \mathfrak{a}$ which is the injectivity.

□

Proof of (8.21):
As usual let $\alpha : R \to S$ be the structural homomorphism of $S : R$, that is $\alpha(a) = a \cdot 1_S$. Then we will first prove the identity and inclusion for the pull-back and then the identity and inclusion for the push-out - in this order. Let us commence:

(i) Consider any $a \in R$ then we will prove that a is contained in the intersection of the $\mathfrak{u}_\lambda \cap R$ if and only if a is contained in the pull-back of the intersection of the $\mathfrak{u}_\lambda$. This will be the first identity:

$$\begin{aligned} a \in \bigcap_{\lambda\in\Lambda} (\mathfrak{u}_\lambda \cap R) \quad &\Longleftrightarrow \quad \forall\, \lambda \in \Lambda \,:\, a \in \mathfrak{u}_\lambda \cap R \\ &\Longleftrightarrow \quad \forall\, \lambda \in \Lambda \,:\, \alpha(a) \in \mathfrak{u}_\lambda \end{aligned}$$

$$\begin{aligned} &\iff \quad \alpha(a) \in \bigcap_{\lambda\in\Lambda} \mathfrak{u}_\lambda \\ &\iff \quad a \in \left(\bigcap_{\lambda\in\Lambda} \mathfrak{u}_\lambda\right) \cap R \end{aligned}$$

(i) Let $\mathfrak{u}$ be the sum of all the $\mathfrak{u}_\lambda$ and consider some a contained in the sum of the pull-backs $\mathfrak{u}_\lambda \cap R$. The sum is generated by the union of the $\mathfrak{u}_\lambda \cap R$ and hence a is of the form

$$a \;=\; b_1 a_1 + \cdots + b_r a_r$$

for some $b_i \in R$ and $a_i \in \mathfrak{u}_{\lambda(i)} \cap R$ for some $\lambda(i) \in \Lambda$. That is $\alpha(a_i) \in \mathfrak{u}_{\lambda(i)}$ and hence we insert a into α. If we denote $s_i := \alpha(b_i) \in S$ then we find (as α is a homomorphism of rings)

$$\alpha(a) \;=\; s_1\,\alpha(a_1) + \cdots + s_r\,\alpha(a_r)$$

As any $\alpha(a_i) \in \mathfrak{u}_{\lambda(i)} \subseteq \mathfrak{u}$ we see, that $\alpha(a)$ is contained in $\mathfrak{u}$ again. And by definition this means $a \in \mathfrak{u} \cap R$, which had to be shown.

(i) By definition of the product of ideals, the elements $c \in (\mathfrak{u} \cap R) \cdot (\mathfrak{v} \cap R)$ are of the following form (for some a_k, $b_k \in R$, such that $\alpha(a_k) \in \mathfrak{u}$ and $b_k \in \mathfrak{b}$)

$$c \;=\; \sum_{k=1}^{n} a_k b_k$$

Therefore find $\alpha(a_k)\alpha(b_k) \in \mathfrak{u} \cdot \mathfrak{v}$, so if we apply α to c and use its homomorphism properties, we find that $\alpha(c) \in \mathfrak{u} \cdot \mathfrak{v}$, as well (see below). But this just is $c \in (\mathfrak{u} \cdot \mathfrak{v}) \cap R$ again

$$\alpha(c) \;=\; \alpha\left(\sum_{k=1}^{n} a_k b_k\right) \;=\; \sum_{k=1}^{n} \alpha(a_k)\alpha(b_k)$$

(ii) Let us denote the set of all $s \in S$ that are finite sums of elements of the form $s_i\,\alpha(a_i)$ where $s_i \in S$ and $a_i \in A$, where $A := \bigcup_\lambda \mathfrak{a}_\lambda$ is the union of all $\mathfrak{a}_\lambda$, by

$$\mathfrak{s} \;=\; \left\{ \sum_{i=1}^{n} s_i\,\alpha(a_i) \;\middle|\; n \in \mathbb{N},\, s_i \in S,\, a_i \in A \right\}$$

We will prove that both sums are identical to this set. In both cases one inclusion is obvious: If $a_i \in \mathfrak{a}_\lambda$ then $s_i\,\alpha(a_i) \in \mathfrak{a}_\lambda S$ and hence any $s \in \mathfrak{s}$ is contained in the sum of all $\mathfrak{a}_\lambda$. Also any $a_i \in A$ is contained in the sum of the $\mathfrak{a}_\lambda$ such that any $s \in \mathfrak{s}$ also is contained in the push-out of the sum of the $\mathfrak{a}_\lambda$. We will see, that the converse inclusions are true, as well and in particular the sums are equal: Consider any element s of the sum of the $\mathfrak{a}_\lambda S$, that is there are some $u_i \in S$ and $h_i \in \mathfrak{a}_{\lambda(i)} S$ such that s is of the form

$$s \;=\; u_1 h_1 + \cdots + u_r h_r$$

By construction any h_i is a sum of elements of the form $v_{i,j}\,\alpha(a_{i,j})$ where $a_{i,j} \in \mathfrak{a}_{\lambda(i)}$ for some

$\lambda(i) \in \Lambda$. That is s is an expression of a form that is contained in $\mathfrak{s}$, since

$$s \;=\; \sum_{i=1}^{r} u_i h_i \;=\; \sum_{i=1}^{r} u_i \sum_{j=1}^{n(i)} v_{i,j}\, \alpha(a_{i,j}) \;=\; \sum_{i=1}^{r}\sum_{j=1}^{n(i)} u_i v_{i,j}\, \alpha(a_{i,j}) \;\in\; \mathfrak{s}$$

Hence the sum of the $\mathfrak{a}_\lambda S$ equals $\mathfrak{s}$. Let us also demonstrate that the push-out of the sum of the $\mathfrak{a}_\lambda$ also is contained in $\mathfrak{s}$: That is we consider any $s \in \mathfrak{a}S$ where $\mathfrak{a}$ is the sum of the $\mathfrak{a}_\lambda$. In particular s is of the form

$$s \;=\; u_1\alpha(a_1) + \cdots + u_r\alpha(a_r)$$

for some $u_i \in S$ and $a_i \in \mathfrak{a} = \langle A \rangle_\mathfrak{i}$. That is there are some $r_{i,j} \in R$ and $a_{i,j} \in \mathfrak{a}_{\lambda(i,j)}$ for some $\lambda(i,j) \in \Lambda$ such that a_i is the sum of the $r_{i,j}a_{i,j}$. And thereby we find that s is contained in $\mathfrak{s}$ again

$$s \;=\; \sum_{i=1}^{r} u_i\, \alpha(a_i) \;=\; \sum_{i=1}^{r} u_i\, \alpha\left(\sum_{j=1}^{n(i)} r_{i,j}a_{i,j}\right) \;=\; \sum_{i=1}^{r}\sum_{j=1}^{n(i)} u_i\, \alpha(r_{i,j})\, \alpha(a_{i,j}) \;\in\; \mathfrak{s}$$

(ii) Let $\mathfrak{a}$ be the intersection of all the $\mathfrak{a}_\lambda$. It remains to prove that any $s \in \mathfrak{a}S$ already is contained in the intersection of all the $\mathfrak{a}_\lambda S$. That is s is of the form

$$s \;=\; u_1\alpha(a_1) + \cdots + u_r\alpha(a_r)$$

for some $u_r \in S$ and $a_i \in \mathfrak{a}$. Fix any $\lambda \in \Lambda$, then $a_i \in \mathfrak{a} \subseteq \mathfrak{a}_\lambda$ such that we have $s \in \mathfrak{a}_\lambda S$, too. But as this is true for any $\lambda \in \Lambda$ we see that s is contained in the intersection of the $\mathfrak{a}_\lambda$ already.

(ii) By definition of the product of ideals $\mathfrak{a} \cdot \mathfrak{b}$ the elements of this ideal are of the form $\sum_i a_i b_i$ for some $a_i \in \mathfrak{a}$ and $b_i \in \mathfrak{b}$. In particular $\alpha(a_i) \in \alpha(\mathfrak{a}) \subseteq \mathfrak{a}S$ and likewise $\alpha(b_i) \in \alpha(\mathfrak{b}) \subseteq \mathfrak{b}S$. As α is a homomorphism of rings, we get

$$\alpha\left(\sum_{i=1}^{n} a_i b_i\right) \;=\; \sum_{i=1}^{n} \alpha(a_i)\alpha(b_i) \;\in\; (\mathfrak{a}S)\cdot(\mathfrak{b}S)$$

Note that the sum is contained in $(\mathfrak{a}S)\cdot(\mathfrak{b}S)$ as this is an ideal in S. That is we have proved $\alpha(\mathfrak{a}\cdot\mathfrak{b}) \subseteq (\mathfrak{a}S)\cdot(\mathfrak{b}S)$ and as $(\mathfrak{a}\cdot\mathfrak{b})S$ is generated by this image set we have found the inclusion from right to left. For the converse inclusion we regard an element $w \in (\mathfrak{a}S)\cdot(\mathfrak{b}S)$ which are of the form [for some $u_k \in \mathfrak{a}S$ and $v_k \in \mathfrak{b}S$]

$$w \;=\; \sum_{k=1}^{n} u_k v_k$$

That is u_k is a finite sum of elements of the form $f_{k,i}\alpha(a_{k,i})$ for some $f_{k,i} \in S$ and $a_{k,i} \in \mathfrak{a}$. Likewise v_k is a finite sum of some $g_{k,j}\alpha(b_{k,j})$ where $g_{k,j} \in S$ and $b_{k,j} \in \mathfrak{b}$. Inserting this into w we find

$$w \;=\; \sum_{k=1}^{n} \left(\sum_{i=1}^{I(k)} f_{k,i}\, \alpha(a_{k,i})\right)\left(\sum_{j=1}^{J(k)} g_{k,j}\, \alpha(b_{k,j})\right) \;=\; \sum_{k=1}^{n}\sum_{i=1}^{I(k)}\sum_{j=1}^{J(k)} f_{k,i}g_{k,j}\, \alpha(a_{k,i}b_{k,j})$$

As $a_{k,i}b_{k,j} \in \mathfrak{a}\cdot\mathfrak{b}$ we hence find that w is an S-linear combination of elements of $\alpha(\mathfrak{a}\cdot\mathfrak{b})$. This

again means, that w is contained in $(\mathfrak{a}\cdot\mathfrak{b})S$ again, by construction of pushed-out ideals.

□

Proof of (8.9):
Let us assume f splits over S in the form $f(t) = \mathrm{lc}(f)(t-s_1)\dots(t-s_n) \in S[t]$ and expand this product denoting the $(k \in \mathbb{N})$-th coefficient of $(t-s_1)\dots(t-s_n)$ by

$$e_k(s_1,\dots,s_n) \;:=\; \left(\prod_{k=1}^{n}(t-s_k)\right)[k]$$

By the theorem of Vieta (7.66) we even know the exact shape of $e_k(s_1,\dots,s_n)$ to be the $(n-k)$-th elementary symmetric polynomial in n-variables $e_k(s_1,\dots,s_n) = (-1)^{n-k}s^{(n)}_{n-k}(s_1,\dots,s_n)$ but this is irrelevant here. We only need, that $e_k(s_1,\dots,s_n)$ is a uniquely determined polynomial in the s_k again. By remark (8.8) $\mathrm{lc}(f)(t-s_1)\dots(t-s_n) = f$ has to be decoded in the following form

$$\forall\, k \in \mathbb{N} \;:\; \alpha(\mathrm{lc}(f))\cdot e_k(s_1,\dots,s_n) \;=\; \alpha(f[k])$$

As β is a homomorphism of rings, it commutes with polynomials and hence we may insert $e_k(s_1,\dots,s_n)$ into β and thereby find the following identity

$$\prod_{k=1}^{n}\big(t-\beta(s_k)\big) \;=\; e_k\big(\beta(s_1),\dots,\beta(s_n)\big) \;=\; \beta\big(e_k(s_1,\dots,s_n)\big)$$

If we insert $\alpha(f[k])$ into β we can again use its homomorphism property and the equation above, to find $f[k] = \mathrm{lc}(f)(t-\beta(s_1))\dots(t-\beta(s_n))$ as an equation in the ring extension $T[t] : R[t]$ induced by $\beta\alpha : R \to T$. In particular f splits over T, too, as we can compute

$$\beta\alpha(f[k]) \;=\; \beta\alpha(\mathrm{lc}(f))\cdot\beta\big(e_k(s_1,\dots,s_n)\big) \;=\; \beta\alpha(\mathrm{lc}(f))\cdot\prod_{k=1}^{n}\big(t-\beta(s_k)\big)$$

□

Proof of (8.24):

(i) By definition any polynomial $f \in R[I]$ only has finitely many non-zero coefficients, and therefore $A(f) := \{\, \alpha \in \mathbb{N}^{\oplus I} \mid f[\alpha] \neq 0 \,\}$ is a finite set. Also $I(\alpha) := \{\, i \in I \mid \alpha_i \neq 0 \,\}$ is a finite set for any $\alpha \in \mathbb{N}^{\oplus I}$. In combination

$$\Omega \;:=\; \bigcup\{\, I(\alpha) \mid \alpha \in A(f) \,\}$$

is a finite subset of I. If $f[\alpha]\,t^\alpha$ is a non-zero term of f then $t^\alpha = \prod_i t_i^{\alpha_i}$ only contains those t_i that belong to some $i \in \Omega$ and therefore $f \in \iota^I_\Omega(R[\Omega])$. And as this is true for any $f \in R[I]$, we get the inclusion from left to right. The converse inclusion is trivial, however.

(ii) By construction of the canonical maps $\iota^J_I(f) = f\,1_{R[J]}$ for any $f \in R[I]$ and under ι^K_J this is mapped to $f\,1_{R[J]}\,1_{R[K]} = f\,1_{R[K]} = \iota^K_I(f)$. Thus we already have $\iota^K_I = \iota^K_J\iota^J_I$. The homomorphism π^J_I exists and is uniquely determined, as it is an evaluation homomorphism, defined on the generating set $\{\, t_j \mid j \in J \,\}$ of $R[J]$, refer to (7.14). Now for any $i \in I$ we get $\pi^J_I\iota^J_I(t_i) = \pi^J_I(t_i) = t_i$. And as both

π_I^J and ι_I^J are homomorphisms of R-algebras this implies $\pi_I^J\iota_I^J(a) = a$ for any $a \in R[I]$, which is property (2). In particular π_I^J is surjective, by (0.10.(a)). Now consider some $f \in \mathfrak{a}\,R[J]$, that is f is of the form $f = f_1\iota_I^J(a_1) + \cdots + f_r\iota_I^J(a_r)$ for some $f_l \in R[J]$ and $a_l \in \mathfrak{a}$. Then we also get property (3) from the computation

$$\pi_I^J(f) \;=\; \pi_I^J\left(\sum_{l=1}^{r} f_l\,\iota_I^J(a_l)\right) \;=\; \sum_{l=1}^{r} \pi_I^J(f_l)\,\pi_I^J\iota_I^J(a_l) \;=\; \sum_{l=1}^{r} \pi_I^J(f_l)\,a_l \;\in\; \mathfrak{a}$$

(iii) Actually this already has been proved in (ii): As $\widehat{a} = \iota_I^J(a)$ we get $\pi_I^J(\widehat{a}) = \pi_I^J\iota_I^J(a) = a$ and hence we only need to apply π_I^J to the equation $\widehat{a} = f_1\widehat{a}_1 + \cdots + f_r\widehat{a}_r$ and let $b_l := \pi_I^J(f_l)$. If we redo the last computation, we thereby find

$$a \;=\; \pi_I^J(\widehat{a}) \;=\; \pi_I^J\left(\sum_{l=1}^{r} f_l\,\widehat{a}_l\right) \;=\; \sum_{l=1}^{r} \pi_I^J(f_l)\,\pi_I^J(\widehat{a}_l) \;=\; \sum_{l=1}^{r} b_l\,a_l$$

(iv) First note that by (8.18) $(\mathfrak{a}\,R[J])R[K] = \mathfrak{a}\,R[K]$ is generally true in any ring extension. Thus the inclusion $\mathfrak{a}\,R[J] \subseteq (\mathfrak{a}\,R[K]) \cap R[J]$ is a general truism, by (8.15), as well. It remains to check the converse inclusion $(\mathfrak{a}\,R[K]) \cap R[J] \subseteq \mathfrak{a}\,R[J]$. To do this we first recollect the definitions of the transferred ideals

$$(\mathfrak{a}\,R[K]) \cap R[J] \;=\; (\iota_J^K)^{-1}\big(\langle\,\iota_I^K(\mathfrak{a})\rangle\big)$$

That is for any element $a \in (\mathfrak{a}\,R[K]) \cap R[J]$ there are some $f_1, \ldots, f_r \in R[K]$ and $a_1, \ldots, a_r \in \mathfrak{a}$ such that [where we use the abbreviations $\widehat{a} = \iota_J^K(a)$ and $\widehat{a}_l = \iota_I^K(a_l)$] a is of the following form

$$\widehat{a} \;=\; f_1\widehat{a}_1 + \cdots + f_r\widehat{a}_r$$

Note that $\iota_J^K\iota_I^J = \iota_I^K$ such that $\widehat{a}_l = \iota_J^K(\iota_I^J(a_i))$. Now by virtue of (ii) the above equation implies that there are some polynomials $b_1, \ldots, b_r \in R[J]$ such that

$$a \;=\; b_1\,\iota_I^J(a_1) + \cdots + b_r\,\iota_I^J(a_r) \;\in\; \mathfrak{a}\,R[J]$$

In the second equality the inclusion $\mathfrak{b} \subseteq (\mathfrak{b}\,R[K]) \cap R[J]$ is (8.15) again. And by (8.18) we also have $(\mathfrak{u} \cap R[J]) \cap R[I] = \mathfrak{u} \cap R[I]$ in general, for any ideal $\mathfrak{u} \trianglelefteq_{\mathrm{i}} R[K]$, in particular for $\mathfrak{u} := \mathfrak{b}\,R[K]$. Hence we get $\mathfrak{b} \cap R[I] \subseteq (\mathfrak{b}\,R[K]) \cap R[J] \cap R[I] = (\mathfrak{b}R[K]) \cap R[I]$. So we only need to check the converse inclusion and start with some element $a \in (\mathfrak{b}\,R[K]) \cap R[I]$. That is $\widehat{a} = f_1\widehat{a}_1 + \cdots + f_r\widehat{a}_r$ for some $f_1, \ldots, f_r \in R[K]$ and $a_1, \ldots, a_r \in \mathfrak{b}$, where $\widehat{a} = \iota_I^K(a)$ and $\widehat{a}_l = \iota_J^K(a_l)$. But then, by (ii) again, we find $a \in \mathfrak{b} \cap R[I]$ from

$$\iota_I^J(a) \;=\; b_1\,a_1 + \cdots + b_r\,a_r \;\in\; \mathfrak{b}$$

(v) For ease of notation we regard $R[I] \subseteq R[J]$ as a subset under ι_I^J. Then for any $\alpha \in \mathbb{N}^{\oplus H}$ and $g[\alpha] \in \mathfrak{a}$ it is clear that $g[\alpha]t^\alpha \in \mathfrak{a}\,R[J]$ and hence $\mathfrak{a}[H] \subseteq \mathfrak{a}\,R[J]$. Conversely, if $g \in \mathfrak{a}\,R[J]$, there g is of the form $g = g_1a_1 + \cdots + g_ra_r$ for some $g_l \in R[J]$ and $a_l \in \mathfrak{a}$. Let us now write $g_l \in R[J]$

as an element of $S[H]$, which is

$$g_l \;=\; \sum_{(\alpha,\beta)\in\mathbb{N}^{\oplus(H\cup I)}} g_l[\alpha,\beta]\,t^{(\alpha,\beta)} \;=\; \sum_{\alpha\in\mathbb{N}^{\oplus H}} \underbrace{\left(\sum_{\beta\in\mathbb{N}^{\oplus I}} g_l[\alpha,\beta]\,t^{\beta}\right)}_{g_l[\alpha]\in S} t^{\alpha}$$

Then it becomes clear that $g \in \mathfrak{a}[H]$, as we can write it in the following form

$$g \;=\; \sum_{l=1}^{r} g_l\,a_l \;=\; \sum_{l=1}^{r}\left(\sum_{\alpha\in\mathbb{N}^{\oplus H}} g_l[\alpha]\,t^{\alpha}\right)a_l \;=\; \sum_{\alpha\in\mathbb{N}^{\oplus H}} \underbrace{\left(\sum_{l=1}^{r} g_l[\alpha]\,a_l\right)}_{\in\mathfrak{a}} t^{\alpha}$$

Thus we also have $\mathfrak{a}\,R[J] \subseteq \mathfrak{a}[H]$ and hence the equality. Let us now prove the isomorphism property. We start by taking a look at the following homomorphism of R-algebras

$$\varrho \;:\; R[J] \;\twoheadrightarrow\; \left(R[I]\,\big/\,\mathfrak{a}\right)[H] \;:\; g \;\mapsto\; \sum_{\alpha\in\mathbb{N}^{\oplus H}} \big(g[\alpha]+\mathfrak{a}\big)t^{\alpha}$$

It is clear, that ϱ is surjective, as $R[I] \twoheadrightarrow R[I]/\mathfrak{a} : g[\alpha] \mapsto g[\alpha]+\mathfrak{a}$ is surjective. So let us take a look at the kernel of ϱ. We find $\operatorname{kn}(\varrho) = \mathfrak{a}[H] = \mathfrak{a}\,R[J]$ from

$$\begin{aligned}
\varrho(g) = 0 \quad &\Longleftrightarrow \quad \forall\,\alpha\in\mathbb{N}^{\oplus H} \;:\; g[\alpha]+\mathfrak{a} = 0\\
&\Longleftrightarrow \quad \forall\,\alpha\in\mathbb{N}^{\oplus H} \;:\; g[\alpha]\in\mathfrak{a}\\
&\Longleftrightarrow \quad g \;\in\; \mathfrak{a}[H]
\end{aligned}$$

Thus ϱ induces the isomorphism given in the claim. Now suppose $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R[I]$ is a prime ideal, then $R[I]/\mathfrak{p}$ is an integral domain and therefore $(R[I]/\mathfrak{p})[H]$ is an integral domain, too. Due to the above isomorphism this means, that $R[J]/(\mathfrak{p}\,R[J])$ is an integral domain, too. And this again tells us that $\mathfrak{p}\,R[J] \trianglelefteq_{\mathrm{i}} R[J]$ is a prime ideal.

(vi) Let us first prove, that these ideals truly form an ascending chain again, that is for $n \geq 1$ we get $(\mathfrak{a}\cap R[I_{n-1}])\,R[J] \subseteq (\mathfrak{a}\cap R[I_n])\,R[J]$. As always $f \in (\mathfrak{a}\cap R[I_{n-1}])\,R[J]$ f is of the form

$$f \;=\; f_1\,\iota^J_{I_{n-1}}(a_1) + \cdots + f_r\,\iota^J_{I_{n-1}}(a_r)$$

for some $f_l \in R[J]$ and $a_l \in \mathfrak{a}\cap R[I_{n-1}]$. The latter is $\iota^J_{I_{n-1}}(a_l) \in \mathfrak{a}$ so let us define $\widehat{a}_l := \iota^{I_n}_{I_{n-1}}(a_l)$ such that $\iota^J_{I_n}(\widehat{a}_l) = \iota^J_{I_{n-1}}(a_l)$. Then we find

$$f \;=\; \sum_{l=1}^{r} f_l\iota^J_{I_{n-1}}(a_l) \;=\; \sum_{l=1}^{r} f_l\iota^J_{I_n}(\widehat{a}_l) \;\in\; \big(\mathfrak{a}\cap R[I_n]\big)\,R[J]$$

It remains to verify the capstone property of $\mathfrak{a}$: The inclusion $(\mathfrak{a}\cap R[I_n])\,R[J] \subseteq \mathfrak{a}$ has been proved in (8.15) and hence we find the inclusion "$\subseteq$" for the (infinite) sum. Now for the converse inclusion "$\supseteq$": Given any $f \in \mathfrak{a} \subseteq R[J]$ we know by (i) that there is a finite subset $\Omega \subseteq J$ such that $f \in \iota^J_\Omega(R[\Omega])$. Now, as Ω is finite and the I_n exhaust J there is a finite level $n \in \mathbb{N}$ such that $\Omega \subseteq I_n$. That is there is some $a \in R[I_n]$ such that $f = \iota^J_{I_n}(a)$. As $f \in \mathfrak{a}$ this means $a \in \mathfrak{a}\cap R[I_n]$

and thereby $f = \iota^J_{I_n}(a) \in (\mathfrak{a} \cap R[I_n])R[J]$.

□

Proof of (8.28):

- Let us first consider the case that $\{ s_i \mid i \in I \} \subseteq S$ generates S as an R module and consider any $q \in Q$. As π is surjective there is some $s \in S$ such that $\pi(s) = q$. This $s \in S$ has a representation as an R-linear combination in terms of the s_i

$$s \;=\; \sum_{i \in I} r_i s_i$$

for some $r_i \in R$ of which only finitely many are non-zero. If we insert this into π and use the properties of π as a homomorphsim of rings, we find that q can be written as the linear combination

$$q \;=\; \pi(s) \;=\; \sum_{i \in I} \pi(r_i)\pi(s_i)$$

As $\pi(r_i) \in \pi(R) \subseteq P$ this is a P-linear combination. As $q \in Q$ has been arbitrary, this means that $\{ \pi(s_i) \mid I \}$ generates Q as a P-module. And in particular the rank of Q as a P-module cannot exceed the rank of S as an R-module

$$[Q : P] \;\leq\; [S : R]$$

- Now say $\{ s_i \mid i \in I \} \subseteq S$ generates S as an R-algebra. That is for any $x \in S$ there are finitely many $s_1, \ldots, s_n \in \{ s_i \mid i \in I \}$ and there is a polynomial $f \in R[t_1, \ldots, t_n]$ such that x can be written as [where $s := (s_1, \ldots, s_n) \in S^n$]

$$x \;=\; f(s_1, \ldots, s_n) \;=\; \sum_{\alpha \in \mathbb{N}^n} f[\alpha]\, s^\alpha$$

If $q \in Q$ is any element again, then we choose some $x \in S$ with $\pi(x) = s$, which is possible, as π is surjective, again. And as above all we need to do is insert this equation into π and use the homomorphism properties

$$q \;=\; \pi(x) \;=\; \sum_{\alpha \in \mathbb{N}^n} \pi\big(f[\alpha]\big)\, \pi(s)^\alpha$$

where $\pi(s) = (\pi(s_1), \ldots, \pi(s_n))$ of course. Again we have $\pi(f[\alpha]) \in \pi(R) \subseteq P$, such that q is a polynomial with coefficients in P in some elements from $\{ \pi(s_i) \mid I \}$. As q has been taken arbitrarily, this means $\{ \pi(s_i) \mid I \}$ generates Q as a P-algebra. And if $S : R$ is finitely generated, then we can choose I to be finite, such that $Q : P$ then is finitely generated, too.

- Now suppose $S : R$ is integral, then we need to show, that $Q : P$ is integral, too. Consider any $q \in Q$ and choose $s \in S$ with $\pi(s) = q$, one more. As $S : R$ is integral, there is some $n \in \mathbb{N}$ and there are $a_0, \ldots, a_{n-1} \in R$ such that

$$s^n + \sum_{k=0}^{n-1} a_k s^k \;=\; 0$$

As always inset this equation into π use the properties of a homomorphism of rings, recall $q = \pi(s)$ and $\pi(a_k) \in \pi(R) \subseteq P$, then we find then q also is integral over P, as it satisfies the equation

$$q^n + \sum_{k=0}^{n-1} \pi(a_k) q^k \;=\; 0$$

□

Proof of (8.29):

(i) As $x \in S$ is integral over R there is a monic polynomial $f \in R[t]$ such that $f(x) = 0$. In particular $f \neq 0$, as f is monic and $\deg(f) \geq 1$, as $f(x) = 0$. Let $n+1 := \deg(f)$ and $k := \operatorname{ord}(f)$ that is $f[k] \neq 0$ but for any $0 \leq j < k$ we have $f[j] = 0$. In other words we write f in the form

$$f(t) \;=\; t^{n+1} + f[n]t^n + \cdots + f[k]t^k \;=\; t^k \left(t^{n+1-k} + f[n]t^{n-k} + \cdots + f[k]t^0 \right)$$

As $x \in \text{NZD}(R)$ is a non-zero-divisor and $f(x) = 0$ this means that the above polynomial in brackets already has to vanish at x. And as $f[k] \neq 0$ we have found a monic polynomial $m \in R[t]$ such that $m(x) = 0$ but $m(0) = f[k] \neq 0$, as claimed

$$m(t) \;:=\; t^{n+1-k} + f[n]t^{n-k} + \cdots + f[k+1]t + f[k]$$

(ii) If $a \in R^*$ then $\alpha(a) \in S^*$ and $\alpha(a)^{-1} = \alpha(a^{-1})$ have already been shown in (1.76.(ii)). So conversely assume $u = \alpha(a) \in S^*$ that is, there is some $u^{-1} \in S$, such that $u^{-1}u = 1_S$. As $S : R$ is integral there is an equation of the form

$$\left(u^{-1}\right)^{n+1} + a_n \left(u^{-1}\right)^n + \cdots + a_1 u^{-1} + a_0 \;=\; 0$$

for some coefficients $a_k \in R$. Let us multiply this equation by u^n (from the right, but this is irrelevant), then only one u^{-1} remains and hence we can turn this into

$$u^{-1} \;=\; -\left(a_n + \cdots + a_1 u^{n-1} + a_0 u^n \right)$$

However $u = \alpha(a) \in \alpha(R) = R\,1_S$ and $\alpha(R)$ is an R-subalgebra of S. Then the equation above implies $u^{-1} \in \alpha(R)$, too, say $u^{-1} = \alpha(b)$. Then $\alpha(ab) = \alpha(a)\alpha(b) = uu^{-1} = 1_S = \alpha(1_R)$. As α is injective we get $ab = 1_R$ and hence $a \in R^*$ with inverse $a^{-1} = b$.

(iii) Suppose there was some $x \in \mathfrak{u}$ such that also $x \in \text{NZD}(S)$. Then by (i) we find some $m \in R[t]$ such that $m(x) = 0$ but $m(0) \neq 0$. Let $\alpha : R \to S : a \mapsto a1_S$ be the structural homomorphism again, that is $as = \alpha(a) \cdot s$ for any $a \in R$, $s \in S$.

$$0 \;=\; m(x) \;= x^{n+1} + \sum_{k=1}^{n} \alpha(m[k]) \cdot x^k + \alpha(m[0])$$

Then, as $x \in \mathfrak{u}$, we find that $\alpha(m[0])$ is contained in $\mathfrak{u}$ from the following equation, below. But this means $m[0] \in \mathfrak{u} \cap R = 0$ such that $m(0) = m[0] = 0$. But this contradicts $m(0) \neq 0$ and therefore,

there could not have been any $x \in \mathfrak{u} \cap \text{NZD}(R)$ and hence $\mathfrak{u} \subseteq \text{ZD}(R)$.

$$\alpha(m[0]) \;=\; -x\left(x^n + \sum_{k=1}^{n} \alpha(m[k]) \cdot x^{k-1}\right) \;\in\; \mathfrak{u}$$

(iv) Let us abbreviate $a := \mathfrak{u} \cap R$. We have already seen in (8.19.(i)) that this is a well-defined ring extension and that $\overline{\alpha}$ is injective, in this case. It remains to verify, that $S/\mathfrak{u} : R/\mathfrak{a}$ is integral again. So consider any $x + \mathfrak{u}$, as $x \in S$ there is a monic polynomial $m \in R[t]$ such that $m(x) = 0$. Inserting $m(x)$ into the canonical homomorphism $x \mapsto x + \mathfrak{u}$ we find

$$\begin{aligned} 0 + \mathfrak{u} \;&=\; m(x) + \mathfrak{u} \;=\; x^{n+1} + \sum_{k=0}^{n} \alpha(m[k]) \cdot x^k + \mathfrak{u} \\ &=\; (x+\mathfrak{u})^{n+1} + \sum_{k=0}^{n} \big(\alpha(m[k]) + \mathfrak{u}\big) \cdot (x+\mathfrak{u})^k \\ &=\; (x+\mathfrak{u})^{n+1} + \sum_{k=0}^{n} \big(\overline{\alpha}(m[k] + \mathfrak{a})\big) \cdot (x+\mathfrak{u})^k \end{aligned}$$

That is $x + \mathfrak{u} \in S/\mathfrak{u}$ satisfies the monic polynomial $t^{n+1} + (m[n] + \mathfrak{a})t^n + \cdots + (m[0] + \mathfrak{a}) \in R/\mathfrak{a}[t]$ and as x has been arbitrary, this means, that $S/\mathfrak{u}/R/\mathfrak{a}$ is integral, again.

(v) Consider any $x/u \in U^{-1}S$, as $x \in S$ and $S : R$ is integral there is a monic polynomial $f \in R[t]$ such that $f(x) = 0$. Say $n + 1 := \deg(f)$, then we define another monic polynomial over $U^{-1}R$:

$$g(t) \;:=\; t^{n+1} + \sum_{k=0}^{n} \frac{f[k]}{u^{n+1-k}}\, t^k$$

Then the following computation shows $g(x/u) = 0 \in U^{-1}S$ and as x/u is arbitrary this shows that the ring extension $U^{-1}S : U^{-1}R$ is integral, too:

$$g\left(\frac{x}{u}\right) \;=\; \frac{x^{n+1}}{u^{n+1}} + \sum_{k=0}^{n} \frac{f[k]}{u^{n+1-k}} \frac{x^k}{u^k} \;=\; \frac{1}{u^{n+1}}\left(t^{n+1} + \sum_{k=0}^{n} f[k]\, t^k\right) \;=\; \frac{f(x)}{u^{n+1}} \;=\; \frac{0}{u^{n+1}}$$

(vi) Let us first prove that $\{1, t, \ldots, t^{n-1}\}$ is a generating set of $R[t]$ as an $R[f]$-module. That is we consider any $g \in R[t]$ and need to find $g_i \in R[f]$ such that

$$g \;=\; g_0 + g_1 t + \cdots + g_{n-1} t^{n-1}$$

We do this by induction on the degree of g: If $\deg(g) < n$ then the claim is obvious, as we can take the $g_i = g[i] \in R$. If $\deg(g) \geq n$ we use division with remainder to write g as $g = qf + r$ for some q, $r \in R[t]$ with $\deg(r) < \deg(f) = n$. As $\deg(q) < \deg(g)$ we may use the induction hypothesis to write q as a linear combination $q = q_0 + q_1 t + \cdots + q_{n-1} t^{n-1}$, then

$$g \;=\; qf + r \;=\; \sum_{i=0}^{n-1} \big(q_i f + r[i]\big) t^i$$

and $g_i := q_i f + r[i] \in R[f]$ again. Thus g is an $R[f]$-linear combination over the t^i. It remains to

prove, that the t^i also are $R[f]$-linearly independent. To do this we have to consider any $g_i \in R[t]$ such that $g_0(f) + g_1(f)t + \cdots + g_{n-1}(f)t^{n-1} = 0$. Let us take those g_i whose sum of degrees is minimal. As $g_0(f) + g_1(f)t + \cdots + g_{n-1}(f)t^{n-1} = 0$ we also get

$$0 + pE[x] \;=\; \sum_{i=0}^{n-1} g_i(f)t^i + fR[t] \;=\; \sum_{i=0}^{n-1} g_i(0)t^i + fR[t]$$

and as $\deg(f) = n$ this means $g_i(0) = 0$ for any $i \in 0 \ldots n-1$. But this means $t \mid g_i$ and hence $g_i(f) = fh_i(f)$ for some $h_i \in R[t]$. Thus we may scratch f from the equation and find another equation $h_0(f) + h_1(f)t + \cdots + h_{n-1}(f)t^{n-1} = 0$ again. But the sum of the degrees of the h_i is n less, in contradiction to the minimality of the degrees of the g_i. Thus we had $g_i = 0$ for any $i \in 0 \ldots n-1$ in the first place and this is the linear independence of $\{ 1, t, \ldots, t^{n-1} \}$.

□

Proof of (8.30):

(i) Let m be a monic polynomial, $n := \deg(m)$ and $X := \{ x^k \mid 0 \leq k < n \}$. Then we need to show that any element $y \in R[x]$ can be written as a linear combination in terms of X. To see this note that y is of the form $y = f(x)$ for some polynomial $f \in R[t]$. As m is monic we may use division with remainder (2.67) to find polynomials q and $r \in R[t]$ such that $f = qm + r$ and $\deg(r) < n$. Then we find $y = r(x)$ from $y = f(x) = q(x) \cdot m(x) + r(x) = q(x) \cdot 0 + r(x) = r(x)$. Now due to the degree of r we have

$$y \;=\; r(x) \;=\; \sum_{k=0}^{n-1} r[k]x^k \;\in\; \mathrm{Lh}_R(X)$$

(ii) In case $n = 1$ this is the statement of (i) precisely. In case $n \geq 2$ we use induction on n: Let us denote $P_0 := R[x_1, \ldots, x_{n-1}]$ then $P = P_0[x_n]$ according to (8.5). And as x_n is integral over R it also is integral over P_0, since $R \subseteq P_0$. So by (i) again, we have

$$[P : P_0] \;=\; [P_0[x_n] : P_0] \;<\; \infty$$

By induction hypothesis we also have $[P_0 : R] < \infty$. Combining these we may use the degree formula (8.7.(iv)) to find the claim

$$[P : R] \;\leq\; [P : P_0] \cdot [P_0 : R] \;<\; \infty$$

(iii) Let $n := [S : R]$ be the degree of the extension and let $\{ s_1, \ldots, s_n \} \subseteq S$ be a generating set of S as an R-module. For any $i \in 1 \ldots k$ choose a representation of xs_i in term of this generating set

$$xs_i \;=\; \sum_{j=1}^{n} a_{i,j}s_j$$

and define the matrix $A := (a_{i,j}) \in \mathrm{mat}_n(R)$. For any other element $y = b_1s_1 + \cdots + b_ns_n$ we let $b := (b_1, \ldots, b_n)$ and thereby get

$$xy \;=\; x\sum_{i=1}^{n} b_is_i \;=\; \sum_{i=1}^{n} b_ixs_i \;=\; \sum_{i=1}^{n}\sum_{j=1}^{n} b_ia_{i,j}s_i \;=\; \sum_{i=1}^{n} [Ab]_is_i$$

By induction it is clear, that $x^k y = [A^k b]_1 s_1 + \cdots + [A^k b]_n s_n$. Thus for any polynomial $f \in R[t]$ we have $f(x)y = [f(A)b]_1 s_1 + \cdots + [f(A)b]_n s_n$. Let $m := c_A$ be the characteristic polynomial of A - recall that this is $m(t) = \det(t\mathbb{1}_n - A)$. Then the Cayley-Hamilton theorem (5.44) tells us, that m is a monic polynomial of degree n satisfying $m(A) = 0 \in \mathrm{mat}_n(R)$. By what we have argued this means that $m(x)y = [m(A)b]_1 s_1 + \cdots + [m(A)b]_n s_n = 0$. By choosing $y = 1_S$ we find that $m(x) = 0$ and hence we have found the monic polynomial required.

(iii) *Alternate proof, that $S : R$ is algebraic, only*: Let $n := [S : R]$ be the degree of the extension. Given any $x \in S$ we consider the set $X := \{\, x^k \mid 0 \leq k \leq n \,\}$. If $\#X \leq n$ then there are some $i < j \in 0 \ldots n$ such that $x^i = x^j$. In this case we may take $f(t) := t^j - t^i \in R[t]$ to find $f(x) = 0$. If $\#X = n + 1$ then we may invoke lemma (3.99.(i)) to find that X is R-linearly dependent. That is there are $a_k \in R$ (not all zero) such that

$$a_n x^n + \cdots + a_1 x + a_0 \cdot 1 \quad = \quad 0$$

Thus we have found a polynomial $f \in R[t]$ of degree n at most, by taking $f[k] := a_k$ such that $f(x) = 0$. And as not all a_k are zero we have $f \neq 0$ and this means x is algebraic over R.

(iv) Consider any $s \in S$, as $S = R[X]$ there are finitely $x_1, \ldots, x_n \in X$ such that $s \in R[x_1, \ldots, x_n]$, according to the construction (8.4). As all the x_i are integral by assumption $R[x_1, \ldots, x_n]$ is finite, due to (ii). But a finite extension is integral by (iii), that is there is a monic polynomial $m \in R[t]$ such that $m(s) = 0$. Yet as s has been arbitrary, this means $S : R$ is integral.

(v) If $S : R$ is integral and finitely generated, then it is precisely the statement of (ii) that $S : R$ also is finite. Conversely if $S : R$ is finite, say $S = \mathrm{Lh}_R\{\, s_1, \ldots, s_k \,\}$ for some $s_1, \ldots, s_k \in S$, then clearly $S = R[s_1, \ldots, s_k]$, as we have the chain of inclusions

$$S \;=\; \mathrm{Lh}_R\{\, s_1, \ldots, s_k \,\} \;\subseteq\; R[s_1, \ldots, s_k] \;\subseteq\; S$$

Hence $S : R$ is finitely generated and also integral, according to (iii).

(vi) For any $a \in R$ it is clear that $m(t) := t - a \in R[t]$ satisfies $m(a1_S) = 0$ and hence $a \in \overline{R}$, such that $R\,1_S \subseteq \overline{R}$. In particular $1_S \in \overline{R}$. It remains to prove, that $\overline{R}$ is a sub-ring if S: Given $x, y \in \overline{R}$ we see that $R[x, y]$ is finitely generated by integral elements and hence $R[x, y] : R$ is finite by (ii). Then again $R[x, y] : R$ is integral, by (iii). In particular $x + y$ and $xy \in R[x, y]$ are integral, that is $x + y$, $xy \in \overline{R}$ and hence this is also is a sub-ring of S.

(vi) Nota the proof of $\int(S : \overline{R}) = \overline{R}$ already uses the next lemma (8.31). Note however, that in the proof of this lemma we did not use this property. We only placed this property here, in order to present the statements in thematic order. No logical loop has been made.

Let us now prove $\int(S : \overline{R}) = \overline{R}$. That is we regard some $s \in S$ such that s is integral over $\overline{R}$ and have to prove that s already is integral over R. Yet as s is integral over $\overline{R}$, the extension $\overline{R}[s] : \overline{R}$ is finite, by (i) and hence integral by (iii). Also $\overline{R} : R$ is integral (by definition of $\overline{R}$) such that from (8.31.(ii)) we find, that $\overline{R}[s] : R$ is integral. In particular s is integral over R, which is $s \in \overline{R}$.

(vii) Take a look at the homomorphism $\varepsilon_x : E[t] \twoheadrightarrow E[x] : f \mapsto f(x)$, which is surjective, by definition of $E[x]$ and let us denote its kernel by $\mathfrak{v}_x := \mathrm{kn}(\varepsilon_x) = \{\, f \in E[t] \mid f(x) = 0 \,\}$. Then we find an induced homomorphism

$$E[t] \big/ _{\mathfrak{v}_x} \xrightarrow{\sim} E[x] \ : \ f + \mathfrak{v}_x \mapsto f(x)$$

As $E[x] \leq_{\mathrm{r}} E[t]$ is a sub-ring, $E[t]$ is a prime ideal, by (2.12). And as x is algebraic over E there is some $f \in \mathfrak{v}_x$ with $f \neq 0$. As $E[t]$ is a PID, any non-zero prime ideal $\mathfrak{v}_x$ of $E[t]$ is maximal, by (2.71) and (2.79). But as $\mathfrak{v}_x$ is maximal, the quotient ring $E[t]/\mathfrak{v}_x$ is a field, by (2.5). And due to the above isomorphism, this means $E[x]$ is a field.

(viii) In (a) $\implies$ (b) we first prove, that S is torsion-free, as an R-module: Consider any $a \in R$ and $s \in S$ such that $as = 0$. If $a = 0$ there is nothing to do, else for $a \neq 0$ - as R is a field - there is an inverse a^{-1} of a such that we get $s = 0$ from the computation

$$0 \ = \ a^{-1}0 \ = \ a^{-1}(as) \ = \ (a^{-1}a)s \ = \ 1_R s \ = \ s$$

It remains to prove, that S even is a field: Consider any $x \in S$ such that $x \neq 0$. As $S : R$ is integral we can choose a minimal $n \in \mathbb{N}$ such that there are some $a_k \in R$ such that we have an equation of the form

$$a_n x^n + \cdots + a_2 x^2 + a_1 x + a_0 1_S \ = \ 0$$

(in fact, there even is an equation with $a_n = 1$). As n is minimal we clearly have $a_n \neq 0$. Suppose we had $a_0 = 0$ then we might pull out an x to arrive at $x(a_n x^{n-1} + \cdots + a_2 x + a_1 1_S) = 0$. But as $x \neq 0$ and S is an integral domain this would mean $a_n x^{n-1} + \ldots a_2 x + a_1 1_S = 0$, in contradiction to n being minimal, as well. Hence we have $a_0 \neq 0$ and, as R is a field, this means a_0 has an inverse $a_n^{-1} \in R$. Thus the equation above can be turned into

$$1_S \ = \ -a_0^{-1}\left(a_n x^n + \cdots + a_2 x^2 + a_1 x\right) \ = \ -a_0^{-1}\left(x^{n-1} + a_{n-1}x^{n-2} + \cdots + a_2 x + a_1\right) x$$

That is we have found $-a_0^{-1}(x^{n-1} + \ldots a_2 x + a_1)$ to be the inverse element of x. And as x has been arbitrary, this means any $x \in S$ is invertible and hence S is a field.

(viii) In (b) $\implies$ (a) it is clear, that S is an integral domain, as we even assume S to be a field. Now consider any $a \in R$ such that $a1_S = 0$. As $S \neq 0$ we have $1_S \neq 0$ and as S is torsion-free, as an R-module, this implies $a = 0$. That is we have established the implication

$$a1_S \ = \ 0 \quad \Longrightarrow \quad a \ = \ 0$$

In other words: If we start with some $a \neq 0$ we have $x := a1_S \in S$ is $x \neq 0$, non-zero, again. And as S is a field x thereby has an inverse $y = x^{-1} \in S$, that is $xy = 1_S$. But as $S : R$ is integral there also is an equation of the form

$$y^{n+1} + a_n y^n + \cdots + a_2 y^2 + a_1 y + a_0 1_S \ = \ 0$$

Multiplying this equation by x^n, bringing all but y on the right-hand side and replacing x^{n-k} by

$a^{n-k}1_S$ again, we arrive at

$$\begin{aligned} y &= -\left(a_n 1_S + \cdots + a_2 x^{n-2} + a_1 x^{n-1} + a_0 x^n\right) \\ &= -\left(a_n + \cdots + a_2 a^{n-2} + a_1 a^{n-1} + a_0 a^n\right) 1_S \end{aligned}$$

That is we find that y is of the form $y = b1_S$ for some $b \in R$ and thereby $1_S = xy = (a1_S)(b1_S) = (ab)1_S$. Now $(ab - 1_R)1_S = 0$ yields $ab = 1_R$ by the implication above and hence $a \in R^*$ with inverse $a^{-1} = b$. As a has been arbitrary this shows, that R is a field.

(ix) If x is integral over $\mathfrak{a}$ then in particular x is integral (over R), as $\mathfrak{a} \subseteq R$. That is $x \in \overline{R}$ but by definition this means that there are some $a_k \in \mathfrak{a}$ such that we have a relation of the form

$$x^n = -\sum_{k=0}^{n-1} a_k x^k \in \mathfrak{a}\overline{R}$$

As $x \in \overline{R}$ this means, that the sum is contained in $\mathfrak{a}\overline{R}$ and hence x in the the radical thereof. Conversely suppose x is contained in the radical of this ideal, that is $x^n \in \mathfrak{a}\overline{R}$ for some $n \in \mathbb{N}$. Then by definition of the push-out there are $a_1, \ldots, a_m \in \mathfrak{a}$ and $x_1, \ldots, x_m \in \overline{R}$ such that

$$x^m = a_1 x_1 + \cdots + a_m x_m$$

Let $M := R[x_1, \ldots, x_m]$, then we have $M \subseteq \overline{R}$ by (vi). And as all the x_i are integral over R and we only took finitely many x_i the R-module M is finitely generated, due to (ii). Clearly we have $x_i M \subseteq M$, by construction and hence

$$x^n M \subseteq \sum_{i=1}^{m} a_i x_i M \subseteq \sum_{i=1}^{m} a_i M \subseteq \mathfrak{a}M$$

as the $a_i \in \mathfrak{a}$. Also $x^m \in M$, by construction again. We now define an R-module-endomorphism $\varphi : M \to M$ by letting $\varphi(y) := x^n y$. Then we have $\varphi(y) \in x^n M \subseteq \mathfrak{a}M$ and as this is true for any $y \in M$ we have $\varphi(M) \subseteq \mathfrak{a}M$. Thus by (5.44.(v)) there are an $N \geq 1$ and some $b_0, \ldots, b_{N-1} \in \mathfrak{a}$ such that $\varphi^N + b_{N-1}\varphi^{N-1} + \cdots + b_1\varphi + b_0 \mathbb{1} = 0 \in \mathrm{end}(M)$. In particular for $1_S \in M$ we have found that x is integral over $\mathfrak{a}$, as it satisfies an equation of the form

$$0_S = \left(\varphi^N + b_{N-1}\varphi^{N-1} + \cdots + b_1\varphi + b_0\mathbb{1}\right)(1_S) = x^{nN} + b_{N-1}x^{n(N-1)} + \cdots + b_1 x^n + b_0 1_S$$

□

Proof of (8.31):

(i) Consider any $x \in T = S[t_1, \ldots, t_n]$. That is there is a polynomial g in n variables over S, such that $x = g(t_1, \ldots, t_n)$. This again means is there are finitely many $b[q] \in S$ and multi-indices $\nu[q] \in \mathbb{N}^n$ such that

$$x = \sum_{q=1}^{N} b[q] t^{\nu(q)} = \sum_{q=1}^{N} \beta\big(b[q]\big) \cdot t^{\nu(q)}$$

Now for any $b[q] \in S = R[s_1, \ldots, s_m]$ there is another polynomial f_q in m variables, such that

$b[g] = f_q(s_1,\ldots,s_m)$. Again there are finitely many $a[p,q] \in R$ amd multiindices $\mu[p,q] \in \mathbb{N}^m$ such that

$$b[q] \;=\; \sum_{p=1}^{M} a[p,q]s^{\mu[p,q]} \;=\; \sum_{p=1}^{M} \alpha\big(a[p,q]\big)\cdot s^{\mu[p,q]}$$

Note that $\beta(s^{\mu[p,q]}) = \beta(s)^{\mu[p,q]}$, as β is a homomorphism of rings. Then - combining these equations - we find an expression that shows, that x can be expressed as a polynomial in the elements $\beta(s_1),\ldots,\beta(s_m)$ and $t_1,\ldots,t_n$. And as x has been arbitrary this means that $T : R$ is generated by these elements, as an R-algebra:

$$\begin{aligned} x &= \sum_{q=1}^{N} \beta\left(b[q]\right)\cdot t^{\nu(q)} \\ &= \sum_{q=1}^{N} \beta\left(\sum_{p=1}^{M} \alpha\big(a[p,q]\big)\cdot s^{\mu[p,q]}\right)\cdot t^{\nu(q)} \\ &= \sum_{q=1}^{N}\sum_{p=1}^{M} \beta\alpha\big(a[p,q]\big)\cdot \beta(s)^{\mu[p,q]}\, t^{\nu[q]} \\ &= \sum_{q=1}^{N}\sum_{p=1}^{M} a[p,q]\,\beta(s)^{\mu[p,q]}\, t^{\nu[q]} \end{aligned}$$

(ii) Consider two ring extensions $\alpha : R \to S$ and $\beta : S \to T$ such that $\beta\alpha : R \to T$ is integral. Then we will first prove, that $T : S$ is integral, too: So pick up any $x \in T$. By assumption there is some polynomial $m \in R[t]$ such that m is monic and $m(x) = 0$. Let us denote

$$\alpha(m) \;:=\; \sum_{k=0}^{\infty} \alpha\big(m[k]\big)t^k \;\in\; S[t]$$

Clearly $n := \alpha(m)$ is a monic polynomial over S. And by construction the R-algebra T uses the scalar multiplication $ax = \beta\alpha(a)\cdot x$. Likewise we have $sx = \beta(s)\cdot x$ in the S-algebra T and therefore

$$0 \;=\; m(x) \;=\; \beta\alpha(m)(x) \;=\; \beta(n)(x) \;=\; n(x)$$

Thus we have found a monic polynomial $n \in S[t]$ such that $n(x) = 0$ which means that x is integral over S. As x has been arbitrary we truly have an integral extension $T : S$.

(ii) We will now prove that (supposed that $\beta\alpha : R \to T$ is integral and β is injective) $S : R$ is integral, too. Thus consider any $s \in S$ and let $x := \beta(s)$. By assumption there is a monic polynomial $m \in R[t]$ such that $m(x) = 0$. We need to verify that $m(s) = 0$, too:

$$\begin{aligned} 0 &= m(x) \;=\; \sum_{k=0}^{\infty} \beta\alpha\big(m[k]\big)\cdot\beta(s)^k \\ &= \beta\left(\sum_{k=0}^{\infty} \alpha\big(m[k]\big)\cdot s^k\right) \;=\; \beta\big(m(s)\big) \end{aligned}$$

Now, as β is injective, this implies $m(s) = 0$ and as s has been arbitrary this means, that the whole extension $S : R$ is integral.

(ii) Conversely suppose both $\alpha : R \to S$ and $\beta : S \to T$ are integral, then we will prove that $\beta\alpha : R \to T$ is integral, too: So pick up any $x \in T$, by assumption there is a monic polynomial $n \in S[t]$ such that $n(x) = 0$. Let $d := \deg(n)$ and take $N := R[n[0], n[1], \ldots, n[d]] \subseteq S$. By construction we have $n \in N[t]$ and still $n(x) = 0$. So by (8.30.(i)) we have $[N[x] : N] < \infty$. But as N is generated by finitely many elements, that are integral over R (8.30.(v)) also tells us $[N : R] < \infty$. Therefore, due to (8.7.(iv)), we get

$$\big[N[x] : R\big] \;\leq\; \big[N[x] : N\big] \cdot \big[N : R\big] \;<\; \infty$$

That is $N[x] : R$ is finite and hence integral - by (8.30.(v)) again - such that there is some monic polynomial $m \in R[t]$ with $m(x) = 0$. Now, as x has been arbitrary this means $T : R$ is an integral extension.

(iii) If S is a finitely generated R-module, say $S = \mathrm{Lh}_R\{ s_1, \ldots, s_m \}$ and T is a finitely generated S-module, say $T = \mathrm{Lh}_S\{ t_1, \ldots, t_n \}$, then we have seen in (8.7.(i)), that $T = \mathrm{Lh}_R\{ s_i t_j \mid i \in 1 \ldots m, j \in 1 \ldots n \}$. In particular T is finitely generated as an R-module.

(iii) Conversely suppose T is a finitely generated R-module, then it is easy to see that T also is a finitely generated S-module: Say $T = \mathrm{Lh}_R\{ t_1, \ldots, t_n \}$ and consider any $x \in T$. That is $x = a_1 t_1 + \ldots a_n t_n$ for some $a_1, \ldots, a_n \in R$. By definition of the scalar multiplications on T this means $x = s_1 t_1 + \cdots + s_n t_n$, where we let $s_k := \alpha(a_k)$. That is $x \in \mathrm{Lh}_S\{ t_1, \ldots, t_n \}$ and as x was arbitrary we have found that $\{ t_1, \ldots, t_n \}$ also generates T as an S-module. In particular T is finitely generated as an S-module.

We now assume that R is a PID and that β is injective and need to show, that in this case S is a finitely generated R-module. To do this note, that $\beta(S) \subseteq T$ is an R-sub-module of T. But as T is finitely generated (as an R-module) and R is a PID, (3.104.(ii)) tells us that $\beta(S)$ is finitely generated as well. That is there are some $s_1, \ldots, s_n \in S$ such that $\beta(s_1), \ldots, \beta(s_n)$ generate $\beta(S)$ as an R-module. If now $x \in S$ is any element, then there are $a_1, \ldots a_n \in R$ such that

$$\begin{aligned}
\beta(s) \;&=\; \sum_{k=1}^{n} a_k \beta(s_k) \;=\; \sum_{k=1}^{n} \beta\alpha(a_k) \cdot \beta(s_k) \\
&=\; \beta\left(\sum_{k=1}^{n} \alpha(a_k) \cdot s_k \right) \;=\; \beta\left(\sum_{k=1}^{n} a_k s_k \right)
\end{aligned}$$

As β is injective we conclude $s = a_1 s_1 + \cdots + a_n s_n$. And as this is true for any $x \in S$, we see that $\{ s_1, \ldots, s_n \}$ generates S as an R module, that is $S : R$ is a finite ring extension.

□

Proof of (8.69):

(i) If $\ell(\mathcal{P}) = \mathrm{kdim}(R)$, then in particular $\mathrm{kdim}(R) < \infty$. Suppose $\mathcal{P}$ was not maximal, then there was some $\mathcal{P}' \in \mathrm{CPI}(R)$ with $\mathcal{P} < \mathcal{P}'$ and in particular $\ell(\mathcal{P}) < \ell(\mathcal{P}')$. But $\mathrm{kdim}(R) < \ell(\mathcal{P}')$ is absurd, such that $\mathcal{P}$ has to be maximal.

(ii) Consider any CPI $\mathfrak{p}_0 \subset \ldots \subset \mathfrak{p}_r$ in R. Then we pull this chain back into S, that is we define the

following ideals in S

$$\mathfrak{q}_i \;:=\; \varphi^{-1}(\mathfrak{p}_i) \;=\; \{\, x \in S \mid \varphi(x) \in \mathfrak{p}_i \,\}$$

These are prime ideals: If $xy \in \mathfrak{q}_i$ then $\varphi(x)\varphi(y) = \varphi(xy) \in \mathfrak{p}_i$ and as $\mathfrak{p}_i$ is prime we get $\varphi(x) \in \mathfrak{p}_i$ or $\varphi(y) \in \mathfrak{p}_i$ which again is $x \in \mathfrak{q}_i$ or $y \in \mathfrak{q}_i$. From the construction it also is clear that the $\mathfrak{q}_i$ form an ascending chain

$$\mathfrak{q}_0 \;\subseteq\; \mathfrak{q}_1 \;\subseteq\; \ldots \;\subseteq\; \mathfrak{q}_r$$

Assume we had $\mathfrak{q}_{i-1} = \mathfrak{q}_i$ for some $i \in 1 \ldots r$. Then also $\varphi(\mathfrak{q}_{i-1}) = \varphi(\mathfrak{q}_i)$. But as φ is surjective we have $\varphi(\mathfrak{q}_i) = \varphi(\varphi^{-1}(\mathfrak{p}_i)) = \mathfrak{p}_i$ for any subset $\mathfrak{p}_i \subseteq R$, according to (0.10). That is we would have $\mathfrak{p}_{i-1} = \mathfrak{p}_i$, which is untrue. Thus $\mathfrak{q}_{i-1} \subset \mathfrak{q}_i$ which means that we have found a CPI in S of length r as well. So there are two cases: (1) If $r = \operatorname{kdim}(R) < \infty$ then we find a CPI in S of length r and hence $\operatorname{kdim}(R) = r \leq \operatorname{kdim}(S)$. (2) If $\operatorname{kdim}(R) = \infty$ then there are CPI in R of undounded length r. Then we conclude, that S features CPI of unbounded length, too and hence $\operatorname{kdim}(S) = \infty = \operatorname{kdim}(R)$. In both cases we have $\operatorname{kdim}(R) \leq \operatorname{kdim}(S)$, as claimed.

(iii) Consider any prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ of $\operatorname{height}(\mathfrak{p}) = 0$. We want to prove, that $\mathfrak{p}$ is minimal. So pick up any $\mathfrak{p}' \trianglelefteq_{\mathrm{i}} R$ such that $\mathfrak{p}' \subseteq \mathfrak{p}$. Suppose $\mathfrak{p}' \neq \mathfrak{p}$ then we had a CPI $(\mathfrak{p}', \mathfrak{p}) \in \operatorname{CPI}(R)$ of length 1. But as $\operatorname{height}(\mathfrak{p}) = 0$ no such chain exists and therefore $\mathfrak{p}' = \mathfrak{p}$.

Conversely consider any $\mathfrak{p} \in \operatorname{Smin}(R)$ and any CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$ in R with $\mathfrak{p}_r = \mathfrak{p}$. In particular $\mathfrak{p}_0 \subseteq \mathfrak{p}$. As $\mathfrak{p}$ is minimal, this implies $\mathfrak{p}_0 = \mathfrak{p} = \mathfrak{p}_r$ which means $r = 0$. As this is true for any $\operatorname{CPI}^{\mathfrak{p}}(R)$ we conclude $\operatorname{height}(\mathfrak{p}) = 0$. means

(iv) If $(\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$ is a chain of prime ideals of R, then by (2.19.(iii)) we find a chain of pirime ideals $(\mathfrak{p}_0/\operatorname{NIL}(R), \ldots, \mathfrak{p}_r/\operatorname{NIL}(R))$ of $R/\operatorname{NIL}(R)$ and vice versa, as the spectra of R and $R/\operatorname{NIL}(R)$ are in one-to-one correspondence. But as this correspondence obviously preserves inclusion and length we have both $\operatorname{kdim}(R) \leq \operatorname{kdim}(R/\operatorname{NIL}(R))$ and $\operatorname{kdim}(R/\operatorname{NIL}(R)) \leq \operatorname{kdim}(R)$.

(v) As $\operatorname{Smax}(R) \subseteq \operatorname{Spec}(R) \subseteq \operatorname{Ideal}(R)$ the supremum of all the $\operatorname{height}(\mathfrak{m})$ where $\mathfrak{m} \in \operatorname{Smax}(R)$ yields the lowest number. Hence it suffices to find a maximal ideal $\mathfrak{m}$ such that for any ideal $\mathfrak{a}$ we have $\operatorname{height}(\mathfrak{a}) \leq \operatorname{height}(\mathfrak{m})$.

If $\operatorname{kdim}(R) < \infty$, then we pick up a CPI $(\mathfrak{q}_0, \ldots, \mathfrak{q}_n)$ with $n = \operatorname{kdim}(R)$. Now by (i) we have $\mathfrak{m} := \mathfrak{q}_n \in \operatorname{Smax}(R)$. If now $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is any proper ideal and $\mathfrak{p} \in \operatorname{Spec}(R)$ is any prime ideal with $\mathfrak{a} \subseteq \mathfrak{p}$, then we take a look at a CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ with $\mathfrak{p}_m = \mathfrak{p}$ and $m = \operatorname{height}(\mathfrak{p})$. As $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ is a CPI in R we have $\operatorname{height}(\mathfrak{p}) = m \leq \operatorname{kdim}(R) = n = \operatorname{height}(\mathfrak{m})$. This means $\operatorname{height}(\mathfrak{a}) \leq \operatorname{height}(\mathfrak{m})$, as needed. And for $\mathfrak{a} = R$ this inequality is satisfied trivially, as we defined $\operatorname{height}(R) = -1 \leq 0 \leq n = \operatorname{height}(\mathfrak{m})$.

If $\operatorname{kdim}(R) = \infty$ there are CPIs of unbounded length. If the largest ideal of these is not maximal already, we can even append such a chain by a maximal ideal containing it. Hence R also features CPIs of unbounded length ending in maximal ideals and hence the supremum of the length of these chains is infinite, too. Again all suprema are equal - in this case equal to infinity.

(vi) Pick up a CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ with $\mathfrak{p}_m = \mathfrak{p}$, as $\mathfrak{p} \subseteq \mathfrak{q}$, by assumption, this gives rise to a CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m, \mathfrak{q})$ of length $m+1$. Thus if $\mathfrak{p}$ had infinite height, then we could find CPI of unbounded

length ending in $\mathfrak{p}$ and therefore also even longer CPI, ending in $\mathfrak{q}$ such that $\text{height}(\mathfrak{p}) = \infty$ implies $\text{height}(\mathfrak{q}) = \infty$, too. So by assumption $\text{height}(\mathfrak{q}) < \infty$ we also have $\text{height}(\mathfrak{p}) < \infty$.

Therefore we may choose a CPI, as above, with $m = \text{height}(\mathfrak{p})$. As this can be appended to a CPI of length $m+1$ ending in $\mathfrak{q}$, this ideal has height $m+1$ at least. Altogether we conclude

$$\text{height}(\mathfrak{p}) \;=\; m \;<\; m+1 \;\leq\; \text{height}(\mathfrak{q})$$

(vii) Suppose $\mathfrak{p}$ was *not* minimal over $\mathfrak{a}$, that is there is some prime ideal $\mathfrak{p}' \in \text{Spec}(R)$, such that $\mathfrak{a} \subseteq \mathfrak{p}' \subset \mathfrak{p}$. In particular we have $\text{height}(\mathfrak{p}') < \text{height}(\mathfrak{p})$ by (vi). But as $\mathfrak{a} \subseteq \mathfrak{p}'$ we also have $\text{height}(\mathfrak{a}) \leq \text{height}(\mathfrak{p}')$ and together that is

$$\text{height}(\mathfrak{p}) \;=\; \text{height}(\mathfrak{a}) \;\leq\; \text{height}(\mathfrak{p}') \;<\; \text{height}(\mathfrak{p})$$

a contradiction. Thus there is no such $\mathfrak{p}'$ and hence $\mathfrak{p}$ is minimal over $\mathfrak{a}$. It remains to verify the following identity of the height of $\mathfrak{a}$

$$\text{height}(\mathfrak{a}) \;\;=\;\; \min\{\, \text{height}(\mathfrak{p}) \mid \mathfrak{p} \in \mathbb{V}(\mathfrak{a})_* \,\}$$

As $\mathfrak{a} \neq R$ is proper there is a maximal ideal $\mathfrak{m}$ of R containing $\mathfrak{a} \subseteq \mathfrak{m}$, by (2.4.(ii)). Now by (2.18.(iv)) there is a prime ideal $\mathfrak{p}$ of R minimal over $\mathfrak{a}$, with $\mathfrak{a} \subseteq \mathfrak{p} \subseteq \mathfrak{m}$ and in particular $\mathfrak{p} \in \mathbb{V}(\mathfrak{a})_*$. Thus the set, we take the minimum over, is non-empty and hence the minimum is well-defined.

Recall that $\text{height}(\mathfrak{a}) = \min\{\, \text{height}(\mathfrak{p}) \mid \mathfrak{p} \in \mathbb{V}(\mathfrak{a}) \,\}$, by definition. As $\mathbb{V}(\mathfrak{a})_* \subseteq \mathbb{V}(\mathfrak{a})$ is a subset, we conclude that $\text{height}(\mathfrak{a})$ cannot exceed the minimum above. Conversely let $\mathfrak{p} \in \mathbb{V}(\mathfrak{a})$ such that $\text{height}(\mathfrak{p})$ is minimal, that is $\text{height}(\mathfrak{p}) = \text{height}(\mathfrak{a})$. Then we have argued obove, that $\mathfrak{p}$ is minimal over $\mathfrak{a}$ that is $\mathfrak{p} \in \mathbb{V}(\mathfrak{a})_*$. Thus we find that the minimal height is assumed by an element of the subset $\mathbb{V}(\mathfrak{a})_*$ and hence the minima over $\mathbb{V}(\mathfrak{a})$ and $\mathbb{V}(\mathfrak{a})_*$ are equal.

(ix) By (8.65.(ii)) there is a one-to-one correspondence between the prime ideals of $R_\mathfrak{p}$ and the prime ideals of R, contained in $\mathfrak{p}$. Thus any CPI $(\mathfrak{u}_0, \ldots, \mathfrak{u}_m)$ of $R_\mathfrak{p}$ is of the form $\mathfrak{u}_k = \mathfrak{p}_k R_\mathfrak{p}$ for a CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ of R with $\mathfrak{p}_m \subseteq \mathfrak{p}$. If one has CPIs of length m, then so does the other. So if $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ is the CPI of R with $\mathfrak{p}_m = \mathfrak{p}$ and $m = \text{height}(\mathfrak{p})$ then we can conclude $\text{kdim}(R_\mathfrak{p}) \geq \text{height}(\mathfrak{p})$, as we get the CPI $(\mathfrak{p}_0 R_\mathfrak{p}, \ldots, \mathfrak{p}_m R_\mathfrak{p})$ of $R_\mathfrak{p}$. But conversely if $(\mathfrak{u}_0, \ldots, \mathfrak{u}_m)$ is the CPI of $R_\mathfrak{p}$ with $\text{kdim}(R_\mathfrak{p}) = m$ then this corresponds to some CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ of R with $\mathfrak{p}_m \subseteq \mathfrak{p}$ and hence $\text{height}(\mathfrak{p}) \geq \text{kdim}(R_\mathfrak{p})$, as well. And if one has infinite dimension, there are arbitrarily long CPI, so the other has infinite dimension, as well.

(x) As R is finite-dimensional, so is $R/\mathfrak{a}$, as any CPI $(\overline{\mathfrak{q}}_0, \ldots, \overline{\mathfrak{q}}_s)$ in $R/\mathfrak{a}$ is inherited from a CPI of R, by the correspondence theorem of ideals (1.71). That is any $\overline{\mathfrak{q}}_j$ is of the form $\overline{\mathfrak{q}}_j = \mathfrak{q}_j/\mathfrak{a}$ for some prime ideal $\mathfrak{q}_j \in \text{Spec}(R)$ with $\mathfrak{a} \subseteq \mathfrak{q}_j$. So pick up such a CPI with $s = \text{kdim}(R/\mathfrak{a})$. As $\mathfrak{a} \subseteq \mathfrak{q}_0$ we have $\text{height}(\mathfrak{a}) \leq \text{height}(\mathfrak{q}_0)$. Thereby $\text{height}(\mathfrak{p}_0)$ is finite, as R was assumed to be finite-dimensional and hence *any* CPI in R is of finite length. Thus we may also pick up a CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$ of R such that $\mathfrak{p}_r = \mathfrak{q}_0$ and $r = \text{height}(\mathfrak{q}_0)$. Let us attach these chains in $\mathfrak{p}_r = \mathfrak{q}_0$:

$$(\mathfrak{p}_0, \ldots, \mathfrak{p}_r = \mathfrak{q}_0, \mathfrak{q}_1, \ldots, \mathfrak{q}_s) \;\;\in\;\; \text{CPI}(R)$$

This is a chain of length $r+s$ in R and thereby we have $\operatorname{kdim}(R) \geq r+s$. But as $r = \operatorname{height}(\mathfrak{q}_0)$ and $s = \operatorname{kdim}(R/\mathfrak{a})$ by construction, this means $\operatorname{kdim}(R) \geq \operatorname{height}(\mathfrak{q}_0) + \operatorname{kdim}(R/\mathfrak{a})$. But we also have $\operatorname{height}(\mathfrak{q}_0) \geq \operatorname{height}(\mathfrak{a})$ and thereby the claim

$$\operatorname{kdim}(R) \;\geq\; \operatorname{height}(\mathfrak{q}_0) + \operatorname{height}\left(R\Big/\mathfrak{a}\right) \;\geq\; \operatorname{height}(\mathfrak{a}) + \operatorname{height}\left(R\Big/\mathfrak{a}\right)$$

(xi) As $\operatorname{height}(\mathfrak{q}) < \infty$ is finite, so is $\operatorname{height}(\mathfrak{q}/\mathfrak{p})$. So let $\mathfrak{q}_0/\mathfrak{p} \subset \ldots \subset \mathfrak{q}_s/\mathfrak{p}$ be a CPI in $R/\mathfrak{p}$ such that $\mathfrak{q}_s/\mathfrak{p} = \mathfrak{q}/\mathfrak{p}$ and $s = \operatorname{height}(\mathfrak{q}/\mathfrak{p})$. Note that this is $\mathfrak{q}_s = \mathfrak{q}$. Now suppose we had $\mathfrak{q}_0 \neq \mathfrak{p}$, as $\mathfrak{p} \subseteq \mathfrak{q}_0$ by correspondence, the non-identity means $0 \subset \mathfrak{q}_0/\mathfrak{p}$. But as $\mathfrak{p}$ is a prime ideal $0 \in \operatorname{Spec}(R/\mathfrak{p})$ is a prime ideal. Thus $0 \subset \mathfrak{q}_0/\mathfrak{p} \subset \ldots \subset \mathfrak{q}_s/\mathfrak{p}$ would be a even longer chain, contradicting the maximality of $s = \operatorname{height}(\mathfrak{q}/\mathfrak{p})$. Thus we conclude $\mathfrak{q}_0 = \mathfrak{p}$, as well. Also as $\mathfrak{p} \subseteq \mathfrak{q}$ the height of $\mathfrak{p}$ is finite, too and hence we may pick up another CPI $\mathfrak{p}_0 \subset \ldots \subset \mathfrak{p}_r$ in R with $\mathfrak{p}_r = \mathfrak{p}$ and $r = \operatorname{height}(\mathfrak{p})$. But then we can compose these chains to a CPI of length $r+s$ in R

$$\mathfrak{p}_0 \;\subseteq\; \ldots \;\subset\; \mathfrak{p}_r = \mathfrak{p} = \mathfrak{q}_0 \;\subset\; \mathfrak{q}_1 \;\subset\; \ldots \;\subset\; \mathfrak{q}_s = \mathfrak{q}$$

In particular $\operatorname{height}(\mathfrak{q}) \geq r+s$ such that $\operatorname{height}(\mathfrak{q}/\mathfrak{p}) = s \leq \operatorname{height}(\mathfrak{q}) - r = \operatorname{height}(\mathfrak{q}) - \operatorname{height}(\mathfrak{p})$.

(viii) Let us first prove the statements for $n = \operatorname{kdim}(R)$: (2) Let $k \in 1\ldots n$ and consider any prime ideal $\mathfrak{p}'$ of R such that $\mathfrak{p}_{k-1} \subseteq \mathfrak{p}' \subseteq \mathfrak{p}_k$. If we even had $\mathfrak{p}_{k-1} \subset \mathfrak{p}' \subset \mathfrak{p}_k$ then we could build up a CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_{k-1}, \mathfrak{p}', \mathfrak{p}_k, \ldots, \mathfrak{p}_n)$ of length $n+1$. But such a chain does not exist as there are no chains of length greater $\operatorname{kdim}(R) = n$. Thus we must either have $\mathfrak{p}' = \mathfrak{p}_{k-1}$ or $\mathfrak{p}' = \mathfrak{p}_k$ and this is the claim $\mathfrak{p}_{k-1} \subset_* \mathfrak{p}_k$, that $\mathfrak{p}_{k-1}$ lies directly under $\mathfrak{p}_k$.

(3) First of all we have $n \leq \operatorname{height}(\mathfrak{p}_n)$, as there is a CPI of length n that ends in $\mathfrak{p}_n$ - namely $(\mathfrak{p}_0, \ldots, \mathfrak{p}_n)$ itself. On the other hand $\operatorname{height}(\mathfrak{p}_n) \leq \operatorname{kdim}(R) = n$ is generally true. Thus we conclude $\operatorname{height}(\mathfrak{p}_n) = n$. Let us now abbreviate $h(k) := \operatorname{height}(\mathfrak{p}_k)$, then we have just seen $h(n) = n$. Also by (vi) we have $h(k-1) = \operatorname{height}(\mathfrak{p}_{k-1}) < \operatorname{height}(\mathfrak{p}_k) = h(k)$ for any $k \in 1\ldots n$, as $\mathfrak{p}_{k-1} \subset \mathfrak{p}_k$ and we deal with a CPI. That is $0 \leq h(0) < \cdots < h(n) = n$. In particular $h(k) \leq n$ for any $k \in 0\ldots n$ and thereby we have found a map

$$h \;:\; 0\ldots n \hookrightarrow 0\ldots n \;:\; k \mapsto \operatorname{height}(\mathfrak{p}_k)$$

This map is injective, as it is strictly monotonous. Well, in the finite set $0\ldots n$ there is one map and one map only, that can do this and this is the identity $h(k) = k$. (1) In particular we have $\operatorname{height}(\mathfrak{p}_0) = 0$ and this already means $\mathfrak{p}_0 \in \operatorname{Smin}(R)$, by (iii). As $\mathfrak{p}_n$ is a prime ideal, it is proper $\mathfrak{p}_n \neq R$ and therefore by (2.4.(ii)) there is a maximal ideal $\mathfrak{m} \in \operatorname{Smax}(R)$ containing it $\mathfrak{p}_n \subseteq \mathfrak{m}$. Suppose we had $\mathfrak{p}_n \neq \mathfrak{m}$ then $\mathfrak{p}_n \subset \mathfrak{m}$ and thereby we had another CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_n, \mathfrak{m})$ of length $n+1 > n = \operatorname{kdim}(R)$. As this cannot be, we have $\mathfrak{p}_n = \mathfrak{m}$ and thereby $\mathfrak{p}_n \in \operatorname{Smax}(R)$.

Now consider the case of a CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$ of length $r = \operatorname{height}(\mathfrak{p}_r)$ and abbreviate $\mathfrak{p} := \mathfrak{p}_r$. Then we take to the localisation $R_\mathfrak{p}$ of R in $\mathfrak{p}$. By CPI-correspondence (8.65.(ii)) the transferred chain $(\mathfrak{p}_0 R_\mathfrak{p}, \ldots, \mathfrak{p}_r R_\mathfrak{p})$ in $R_\mathfrak{p}$ is of length

$$r \;=\; \operatorname{height}(\mathfrak{p}) \;=\; \operatorname{kdim}\big(R_\mathfrak{p}\big)$$

according to (ix). Thus by the above it satisfies properties (1), (2) and (3) of a CPI whose length equals the Krull-dimension. Returning to $(\mathfrak{p}_0,\ldots,\mathfrak{p}_r)$ with CPI-correspondence again, we retain properties (2), (3) and $\mathfrak{p}_0 \in \mathrm{Smin}(R)$. This is the shortcut, bu of course it is possible to redo the above arguments with the CPI $(\mathfrak{p}_0,\ldots,\mathfrak{p}_r)$ again.

(xii) Consider $\mathfrak{p} \in \mathrm{Spec}(R)$ with $\mathfrak{p} \subset_* \mathfrak{q}$, in particular we have $\mathfrak{p} \subset \mathfrak{q}$ and therefore $\mathrm{height}(\mathfrak{p}) < \mathrm{height}(\mathfrak{q})$ according to (vi). That is $1+\mathrm{height}(\mathfrak{p}) \leq \mathrm{height}(\mathfrak{q})$ and as this is true for any $\mathfrak{p}$ we have found that the supremum cannot exceed $\mathrm{height}(\mathfrak{q})$.

Conversely, as $\mathfrak{q}$ is of finite height we may pick up a CPI $(\mathfrak{q}_0,\ldots,\mathfrak{q}_s)$ such that $\mathfrak{q}_s = \mathfrak{q}$ and $s = \mathrm{height}(\mathfrak{q})$. Clearly $\mathrm{height}(\mathfrak{q}_{s-1}) \geq s-1$ as it has the $s-1$ prime ideals $\mathfrak{q}_k$ for $k \in 0\ldots s-1$ underneath. Suppose there was an even longer CPI ending in $\mathfrak{q}_{s-1}$ say $(\mathfrak{r}_0,\ldots,\mathfrak{r}_t)$ with $\mathfrak{r}_t = \mathfrak{q}_{s-1}$ and $t > s-1$. Then we could build up the CPI $(\mathfrak{r}_0,\ldots,\mathfrak{r}_t,\mathfrak{q})$ and have $t+1 > s = \mathrm{height}(\mathfrak{q})$ in contradiction to s being the maximal length under $\mathfrak{q}$. Thus we have $\mathrm{height}(\mathfrak{q}_{s-1}) = s-1$.

Now suppose there was some $\mathfrak{q}' \in \mathrm{Spec}(R)$ with $\mathfrak{q}_{s-1} \subset \mathfrak{q}' \subset \mathfrak{q}$. Then we would find a CPI $(\mathfrak{q}_0,\ldots,\mathfrak{q}_{s-1},\mathfrak{q}',\mathfrak{q})$ of length $s+1$ ending in $\mathfrak{q}$. Again this does not exist, as $s = \mathrm{height}(\mathfrak{q})$ is the limit. Thus we have $\mathfrak{q}' = \mathfrak{q}_{s-1}$ or $\mathfrak{q}' = \mathfrak{q}$ and this means $\mathfrak{q}_{s-1} \subset_* \mathfrak{q}$ lies directly under $\mathfrak{q}$. In particular the set inside the supremum is non-empty. But then we have found a $\mathfrak{p} := \mathfrak{q}_{s-1}$ satisfying $\mathfrak{p} \subset_* \mathfrak{q}$ and $\mathrm{height}(\mathfrak{q}) = 1+\mathrm{height}(\mathfrak{p})$ and hence the height of $\mathfrak{q}$ cannot exceed the supremum, as well. Thus both have to be equal.

(xiii) Let us abbreviate the quotient ring by $Q := R/\mathfrak{a}$ and the prime ideal $\overline{\mathfrak{p}} := \mathfrak{p}/\mathfrak{a}$ of Q, then we have to verify the claim $\mathrm{height}(\overline{\mathfrak{p}}) < \mathrm{height}(\mathfrak{p})$: So pick up any CPI $(\mathfrak{q}_0,\ldots,\mathfrak{q}_s)$ in Q ending in $\mathfrak{q}_s = \overline{\mathfrak{p}}$. By the correspondence theorem of ideals (1.71) these $\mathfrak{q}_k$ are of the form $\mathfrak{q}_k = \mathfrak{p}_k/\mathfrak{a}$ for some $\mathfrak{p}_k \in \mathrm{Spec}(R)$ with $\mathfrak{a} \subseteq \mathfrak{p}_k$. That is we have a CPI $(\mathfrak{p}_0,\ldots,\mathfrak{p}_s)$ of length s in R with $\mathfrak{p}_s = \mathfrak{p}$. Now pick up a prime ideal $0 \subseteq \mathfrak{p}_* \subseteq \mathfrak{p}_0$ that is minimal over 0, by (2.18.(iv)). As this is a minimal prime ideal in R we have $\mathfrak{p}_* \subseteq \mathrm{zD}(R)$ by (2.19.(ii)). But by assumption we have $a \in \mathrm{nzD}(R)$ such that $a \notin \mathfrak{p}_*$ whereas $a \in \mathfrak{a} \subseteq \mathfrak{p}_0$. Thus $\mathfrak{p}_* \subset \mathfrak{p}_0$ is strictly contained and thereby we have found a CPI in R of length $s+1$

$$\mathfrak{p}_* \subset \mathfrak{p}_0 \subset \ldots \subset \mathfrak{p}_s = \mathfrak{p}$$

ending in $\mathfrak{p}$. That is $\mathrm{height}(\mathfrak{p}) \geq s+1 > s$. As this is true for any CPI $(\mathfrak{q}_0,\ldots,\mathfrak{q}_s)$ in Q ending in $\overline{\mathfrak{p}}$ we have $\mathrm{height}(\overline{\mathfrak{p}}) < \mathrm{height}(\mathfrak{p})$. If $\overline{\mathfrak{p}}$ is of infinite height, then so is $\mathrm{height}(\mathfrak{p})$.

□

Proof of (8.72):

(i) If $\mathfrak{q}$ is a prime ideal of S, then $\mathfrak{q} \cap R$ is a prime ideal of R, according to (2.17) and it is clear, that $\mathfrak{q}_{i-1} \subseteq \mathfrak{q}_i$ implies $\mathfrak{q}_{i-1} \cap R = \alpha^{-1}(\mathfrak{q}_{i-1}) \subseteq \alpha^{-1}(\mathfrak{q}_i) = \mathfrak{q}_i \cap R$. Now suppose $\mathfrak{q}_{i-1} \cap R = \mathfrak{q}_i \cap R$, as $\mathfrak{q}_{i-1} \subseteq \mathfrak{q}_i$ we get $\mathfrak{q}_{i-1} = \mathfrak{q}_i$ by (8.32.(iii)). But this is untrue, such that $\mathfrak{q}_{i-1} \cap R \subset \mathfrak{q}_i$ for any $i \in 1\ldots r$ such that the pull-back truly is a CPI in R again.

(ii) By induction it is clear, that we only need to take the first step, that is we regard $\mathfrak{p}_0 \subset \mathfrak{p}_1 \in \mathrm{Spec}(R)$ and start with some $\mathfrak{q}_0 \in \mathrm{Spec}(S)$ such that $\mathfrak{q}_0 \cap R = \mathfrak{p}_0$. Then by (8.29.(iv)) $S/\mathfrak{q}_0 : R/\mathfrak{p}_0$ is an integral extension, as well. By the correspondence theorem of ideals $\mathfrak{p}_1/\mathfrak{p}_0$ is a prime ideal

of $R/\mathfrak{p}_0$ and as $\mathfrak{p}_0 \subset \mathfrak{p}_1$ this ideal is non-zero $\mathfrak{p}_1/\mathfrak{p}_0 \neq 0$. By the lying-over theorem (8.32.(i)) there is a prime ideal $\mathfrak{q}_1/\mathfrak{q}_0 \trianglelefteq_{\mathrm{i}} S/\mathfrak{q}_0$ such that

$$\mathfrak{q}_1 \Big/ \mathfrak{q}_0 \cap R \Big/ \mathfrak{p}_0 \;=\; \mathfrak{p}_1 \Big/ \mathfrak{p}_0$$

By the correspondence theorem of ideals again $\mathfrak{q}_1 \in \operatorname{Spec}(S)$ is a prime ideal, as well. It remains to prove $\mathfrak{q}_1 \cap R = \mathfrak{p}_0$. So let us take a closer look at at the identity of the pull-back of $\mathfrak{q}_1/\mathfrak{q}_0$: If $\alpha : R \to S$ is the structural homomorphism, then the induced structural homomorphism $\overline{\alpha}$ maps $a + \mathfrak{p}_0 \mapsto \alpha(a) + \mathfrak{q}_0$ and therefore

$$\begin{aligned} \mathfrak{p}_1 \Big/ \mathfrak{p}_0 &= \mathfrak{q}_1 \Big/ \mathfrak{q}_0 \cap R \Big/ \mathfrak{p}_0 \\ &= \left\{ a + \mathfrak{p}_0 \mid \overline{\alpha}(a + \mathfrak{p}_0) \in \mathfrak{q}_1 \Big/ \mathfrak{q}_0 \right\} \\ &= \left\{ a + \mathfrak{p}_0 \mid \alpha(a) + \mathfrak{q}_0 \in \mathfrak{q}_1 \Big/ \mathfrak{q}_0 \right\} \end{aligned}$$

We also have $\mathfrak{p}_0 = \mathfrak{q}_0 \cap R = \{ a \mid \alpha(a) \in \mathfrak{q}_0 \}$. With these two properties we are able to prove $\mathfrak{p}_1 = \mathfrak{q}_1 \cap R = \{ a \mid \alpha(a) \in \mathfrak{q}_1 \}$. So if we start with $a \in \mathfrak{p}_1$ then $a + \mathfrak{p}_0 \in \mathfrak{p}_1/\mathfrak{p}_0$ and hence $\alpha(a) + \mathfrak{p}_0 \in \mathfrak{q}_1/\mathfrak{p}_0$. But this is $\alpha(a) \in \mathfrak{q}_1$ and therefore $a \in \mathfrak{q}_1 \cap R$. Conversely $a \in \mathfrak{q}_1 \cap R$ means $\alpha(a) \in \mathfrak{q}_1$ and hence $\alpha(a) + \mathfrak{q}_0 \in \mathfrak{q}_1/\mathfrak{q}_0$. By the identity above this means $a + \mathfrak{p}_0 \in \mathfrak{p}_1/\mathfrak{p}_0$ and hence $a \in \mathfrak{p}_1$. Thus we have the equality $\mathfrak{p}_1 = \mathfrak{q}_0 \cap R$.

(iii) By induction it is clear, that we only need to take the first step, that is we regard $\mathfrak{p}_0 \subset \mathfrak{p}_1 \in \operatorname{Spec}(R)$ and start with some $\mathfrak{q}_1 \in \operatorname{Spec}(S)$ such that $\mathfrak{q}_1 \cap R = \mathfrak{p}_1$. The proof however will require several steps: In the first step we will require S to be an *integral domain*. Then we localize S in $\mathfrak{q}_1$ that is we look at $S_{\mathfrak{q}_1}$. As S is an integral domain $\kappa : S \to S_{\mathfrak{q}_1} : x \mapsto x/1$ is injective. Let $\alpha : R \hookrightarrow S : a \mapsto a1_S$ be the structural homomorphism again, as S is R-torsion-free, α is injective, too. Now $S_{\mathfrak{q}_1} : R$ becomes an R-algebra under the structural homomorphism $\alpha_1 := \kappa\alpha$. As both α and κ are injective, so is α_1. That is

$$\alpha_1 \;:\; R \hookrightarrow S_{\mathfrak{q}_1} \;:\; a \mapsto \frac{\alpha(a)}{1}$$

- For any ideal $\mathfrak{p}_0$ we have $\mathfrak{p}_0 \subseteq \mathfrak{p}_0 S_{\mathfrak{q}_1} \cap R$ due to (8.15). We now claim, that the converse inclusion is true, as well. That is we set out on a lengthy journey to prove

$$\mathfrak{p}_0 S_{\mathfrak{q}_1} \cap R \quad\subseteq\quad \mathfrak{p}_0$$

Consider any $a \in \mathfrak{p}_0 S_{\mathfrak{q}_1} \cap R$, then we need to show $a \in \mathfrak{p}_0$. If $a = 0$, then $a \in \mathfrak{p}_0$ is granted, such that we only have to regard the case $a \neq 0$. By assumption a satisfies $\alpha_1(a) \in \mathfrak{p}_0 S_{\mathfrak{q}_1}$. That is there are some $s_i \in S$ and $u_i \in S \setminus \mathfrak{q}_1$ and $p_i \in \mathfrak{p}_0$ such that we have an identity of the form

$$\frac{\alpha(a)}{1} \;=\; \frac{s_1}{u_1} p_1 + \cdots + \frac{s_k}{u_k} p_k$$

By taking $u := u_1 \dots u_k \in S \setminus \mathfrak{q}_1$ and as always $\widehat{u_i} := u/u_i \in R$ we find that $\alpha(a)/1 = y/u$ for

$$y \;:=\; \sum_{i=1}^{k} \widehat{u_i} s_i p_i \;\in\; \mathfrak{p}_0 S$$

By assumption $S : R$ is integral, that is $S = \overline{R} := \mathrm{int}(S : R)$ and hence y is integral over $\mathfrak{p}_0$ as we know from (8.30.(ix)). That is it satisfies an equation $f \in R[t]$ of the form

$$f(y) \;:=\; y^n + f[n-1]y^{n-1} + \cdots + f[1]y + f[0] \;=\; 0$$

where $f[i] \in \mathfrak{p}_0$. On the other hand, as R is a normal domain, $y \in S$ has a minimal polynomial $m_y \in R[t]$, according to (8.37). And therefore we get $f = g m_y$ for some $g \in R[t]$. Now take a look at $\varrho : R \twoheadrightarrow R/\mathfrak{p}_0 : a \mapsto a + \mathfrak{p}_0$ which induces a homomorphism on the polynomial rings

$$\overline{\varrho} \;:\; R[t] \twoheadrightarrow {}^{R}\Big/_{\mathfrak{p}_0}[t] \;:\; f \mapsto \overline{f} := \sum_{k \in \mathbb{N}} \big(f[k] + \mathfrak{p}_0\big) t^k$$

Inserting $f = g m_y$ we get $t^n = \overline{f} = \overline{g}\,\overline{m}_y$ and as $R/\mathfrak{p}_0$ is an integral domain this means $\overline{m}_y = t^r$ and $\overline{g} = t^{n-r}$ for some $r \in 0 \dots n$. That is m_y is of the form

$$m_y \;=\; t^r + m_y[r-1]t^{r-1} + \cdots + m_y[1]t + m_y[0]$$

for some $m_y[i] \in \mathfrak{p}_0$. Let $F := \mathrm{quot}(S)$, which is possible, as we assumed S to be an integral domain, for now, and consider $S_{\mathfrak{q}_0} \subseteq F$ as a subset, canonically. Then $\alpha(a)/1 = y/u$ turns into the equation $1/\alpha(a) = u/y$ in F. Note that $\alpha(a) \neq 0$, as S is R-torsion free and hence $y \neq 0$. And thereby we get

$$\begin{aligned}
0 \;&=\; \frac{1}{\alpha(a)^r} m_y(y) \;=\; \frac{u^r}{y^r}\left(y^r + \sum_{k=0}^{r-1} m_y[k] y^k\right) \\
&=\; u^r + \sum_{k=0}^{r-1} m_y[k] \frac{u^r}{y^r} y^k \;=\; u^r + \sum_{k=0}^{r-1} m_y[k] \frac{u^{r-k}}{y^{r-k}} u^k \\
&=\; u^r + \sum_{k=0}^{r-1} m_y[k] \frac{1}{\alpha(a)^{r-k}} u^k \;=\; u^r + \sum_{k=0}^{r-1} \frac{\alpha(m_y[k])}{\alpha(a)^{r-k}} u^k
\end{aligned}$$

Note that for any $a \in R$ and $x \in S$ we have $ax = \alpha(a) \cdot x$ by definition of a ring extension. The scalar multiplication with $m_y[k]$ turned into a multiplication with $\alpha(m_y[k]) = \alpha(m_y[k])/1$ in F. If we take $E := \mathrm{quot}(R)$ then $E \hookrightarrow F$ by $a/b \mapsto \alpha(a)/\alpha(b)$, as $\alpha(a)/\alpha(b) = \alpha(c)/\alpha(d)$ implies $\alpha(ad) = \alpha(bc)$ which in turn yields $ad = bc$ [as α is injective] such that $a/b = c/d$ again. In this sense we regard E as a subset of F. Then $\alpha(m_y[k])/\alpha(a)^{r-k} = m_y[k]/a^{r-k} \in E$ and thereby we have found a monic polynomial

$$m_u \;:=\; \frac{1}{a^r} m_y \;=\; t^r + \sum_{k=0}^{r-1} \frac{m_y[k]}{a^{r-k}} t^k \;\in\; E[t]$$

such that $m_u(u) = 0$. We claim that m_u truly is the minimal polynomial of u: If $h \in E[t]$ is any

other polynomial with $h(u) = 0$ and $d := \deg(h) \geq 0$, then in $F[t]$ we have

$$0 \;=\; \alpha(a)^d h(u) \;=\; \frac{y^d}{u^d} \sum_{k=0}^{d} h[k] u^k \;=\; \sum_{k=0}^{d} h[k] \alpha(a)^{d-k} y^k$$

The latter is a polynomial in $E[t]$ that turns y to 0. Hence m_y divides this polynomial $m_y \mid a^d h$ in $E[t]$. By construction we have $m_u = (1/a^r) m_y$ and hence $m_y = a^r m_u$. Thus we have

$$a^r m_u \;\mid\; a^d h \;\text{ in } E[t]$$

As $0 \neq a \in E$ we can just omit it. Then we have $m_u \mid h$ and as this is true for any polynomial $h \in E[t]$, $h \neq 0$ we have found $m_u E[t] = \{\, h \in E[t] \mid h(u) = 0 \,\}$, that is m_u is the minimal polynomial of u. But as $u \in S$, $S : R$ is integral and R is a normal domain we know $m_u \in R[t]$ by (8.37) again. That is all the coefficients of m_u are elements of R

$$\forall\, k \in 0 \ldots r-1 \;\;:\;\; m_u[k] \;=\; \frac{m_y[k]}{a^{r-k}} \;\in\; R$$

That is $a^{r-k} m_u[k] = m_y[k] \in \mathfrak{p}_0$. Suppose $m_u[k] \in \mathfrak{p}_0$ for all $k \in 0 \ldots r-1$, then we had

$$u^r \;\;=\;\; -\sum_{k=0}^{r-1} m_u[k]\, u^k \;\;\in\;\; \mathfrak{p}_0 S$$

But as $\mathfrak{p}_0 \subseteq \mathfrak{p}_0$ we have $\mathfrak{p}_0 S \subseteq \mathfrak{p}_1 S$. And $\mathfrak{p}_1 S = (\mathfrak{q}_1 \cap R) S \subseteq \mathfrak{q}_1$ is generally true, by (8.15). Together this is $\mathfrak{p}_0 S \subseteq \mathfrak{q}_1$ and thereby $u^r \in \mathfrak{q}_1$. But $\mathfrak{q}_1$ is a prime ideal thus we had $u \in \mathfrak{q}_1$ in contradiction to $u \in S \setminus \mathfrak{q}_1$. In conclusion there is some $k \in 0 \ldots r-1$ with $m_u[k] \notin \mathfrak{p}_0$. But we still have $a^{r-k} m_u[k] \in \mathfrak{p}_0$ and as $\mathfrak{p}_0$ is prime, this is $a \in \mathfrak{p}_0$. At long last, we have seen

$$\mathfrak{p}_0 S_{\mathfrak{q}_1} \cap R \;\;=\;\; \mathfrak{p}_0$$

- Recall that we regarded $S_{\mathfrak{q}_1} : R$ as a ring extension (under α_1) here. The identity $\mathfrak{p}_0 S_{\mathfrak{q}_1} \cap R = \mathfrak{p}_0$ is property (a) of the equivalencies in (8.15). Thus we have (b), too which is: There is a prime ideal $\overline{\mathfrak{q}}_0 \in \operatorname{Spec}(S_{\mathfrak{q}_1})$ such that $\overline{\mathfrak{q}}_0 \cap R = \mathfrak{p}_0$. As $\overline{\mathfrak{q}}_0$ is a prime ideal of $S_{\mathfrak{q}_1}$ it corresponds to a prime ideal $\mathfrak{q}_0 = \overline{\mathfrak{q}}_0 \cap S$ of S that satisfies $\mathfrak{q}_0 \cap \big(S \setminus \mathfrak{q}_q\big) = \emptyset$. Refer to (2.129) for details on this correspondence. Then by (8.18) we also get

$$\mathfrak{q}_0 \cap R \;=\; \big(\overline{\mathfrak{q}}_0 \cap S\big) \cap R \;=\; \overline{\mathfrak{q}}_0 \cap R \;=\; \mathfrak{p}_0$$

 As $\mathfrak{q}_0$ and $S \setminus \mathfrak{q}_q$ are disjoint, we have $\mathfrak{q}_0 \subseteq \mathfrak{q}_1$. Now suppose we even had $\mathfrak{q}_0 = \mathfrak{q}_1$, then we also had $\mathfrak{p}_0 = \mathfrak{q}_0 \cap R = \mathfrak{q}_1 \cap R = \mathfrak{p}_1$ in contradiction to $\mathfrak{p}_0 \subset \mathfrak{p}_1$. Thus we also have $\mathfrak{q}_0 \subset \mathfrak{p}_1$ and are done - under the assumption, that S was an integral domain.

- So let us now regard the case of an arbitrary commutative ring S (such that S is torsion-free, as an R-module). Let $\mathfrak{a} := 0 \trianglelefteq_{\mathrm{i}} S$, then $\mathfrak{a} \subseteq \mathfrak{q}_1$ Thus by (2.18.(iv)) there is a minimal prime ideal $\mathfrak{b}$ of S, that also satisfies $\mathfrak{b} \subseteq \mathfrak{q}_1$. And by (2.19) such an ideal is contained in the zero-divisors of S

$$\mathfrak{b} \;\subseteq\; \mathrm{zd}(S) \;=\; \{\, s \in S \mid \exists\, x \in S : x \neq 0, sx = 0 \,\}$$

Now consider any $a \in R$ with $\alpha(a) \in \mathrm{zd}(S)$. That is there is some $x \in S$ such that $x \neq 0$ but $ax = \alpha(a) \cdot x = 0$. By assumption S is R torsion free, that is $ax = 0$ implies $a = 0$ or $x = 0$. As $x \neq 0$ this means $a = 0$ and therefore $\alpha^{-1}(\mathrm{zd}(S)) = \{0\}$. In particular

$$\mathfrak{b} \cap R \;=\; 0$$

Recall that $\alpha : R \hookrightarrow S$ is injective and regard $\pi : S \twoheadrightarrow S/\mathfrak{b}$ defined by $\pi(x) := x + \mathfrak{b}$. Analogous to the above let $\alpha_1 := \pi\alpha$, that is $\alpha_1 : R \to S/\mathfrak{p} : a \mapsto \alpha(a) + \mathfrak{b}$. Suppose $\alpha_1(a) = 0$ that is $\alpha(a) \in \mathfrak{b}$, then $a \in \mathfrak{b} \cap R$ such that $a = 0$. That is $\mathrm{kn}(\alpha_1) = 0$ and hence α_1 is injective again.

- We regard $S_1 : R$ as a ring extension under α_1. This clearly is an integral extension, but you can also use (8.29.(iv)) and note that $\mathfrak{b} \cap R = 0$. As $\mathfrak{b} \subseteq \mathfrak{q}_1$ we get a corresponding prime ideal $\overline{\mathfrak{q}}_1 := \mathfrak{q}_1/\mathfrak{b} \in \mathrm{Spec}(S_1)$. By assumption we have $\mathfrak{q}_1 \cap R = \mathfrak{p}_1$ and hence

$$\overline{\mathfrak{q}}_1 \cap R \;=\; \{\, a \in R \mid \alpha(a) + \mathfrak{b} \in \overline{\mathfrak{q}}_1 \,\} \;=\; \{\, a \in R \mid \alpha(a) \in \mathfrak{q}_1 \,\} \;=\; \mathfrak{q}_1 \cap R \;=\; \mathfrak{p}_1$$

Now note that $S_1 := S/\mathfrak{b}$ is an integral domain, as $\mathfrak{b}$ was a prime ideal. Also S_1 is torsion-free, as it is an integral domain and α_1 is injective. Therefore we can use the case above and find a prime ideal $\overline{\mathfrak{q}}_0$ of S_1 such that $\overline{\mathfrak{q}}_0 \subset \overline{\mathfrak{q}}_1$ and $\overline{\mathfrak{q}}_0 \cap R = \mathfrak{p}_0$. By the correspondence theorem of ideals again, this is of the form $\overline{\mathfrak{q}}_0 = \mathfrak{q}_0/\mathfrak{b}$ for some $\mathfrak{b} \subseteq \mathfrak{q}_0 \in \mathrm{Spec}(S)$. Hence $\mathfrak{q}_0 \subset \mathfrak{q}_1$ follows immediately. And as before we conclude $\mathfrak{q}_0 \cap R = \mathfrak{p}_0$ by

$$\mathfrak{p}_0 \;=\; \overline{\mathfrak{q}}_0 \cap R \;=\; \{\, a \in R \mid \alpha(a) + \mathfrak{b} \in \overline{\mathfrak{q}}_0 \,\} \;=\; \{\, a \in R \mid \alpha(a) \in \mathfrak{q}_0 \,\} \;=\; \mathfrak{q}_0 \cap R$$

□

Proof of (8.73):

(i) If $(\mathfrak{q}_0, \ldots, \mathfrak{q}_n) \in \mathrm{CPI}(S)$ is any chain of prime ideals of S, then we define $\mathfrak{p}_k := \mathfrak{q}_k \cap R$ for any $k \in 0 \ldots n$. Thereby we get $\mathfrak{p}_0 \subseteq \ldots \subseteq \mathfrak{p}_n$. Suppose we had $\mathfrak{p}_{k-1} = \mathfrak{p}_k$ for some $k \in 1 \ldots n$. As also $\mathfrak{q}_{k-1} \subseteq \mathfrak{q}_k$ (8.32.(iii)) would impliy $\mathfrak{q}_{k-1} = \mathfrak{q}_k$, which is untrue. Hence $(\mathfrak{p}_0, \ldots, \mathfrak{p}_n) \in \mathrm{CPI}(R)$ also is a chain of prime ideals and as this is true for any CPI of S we conclude

$$\mathrm{kdim}(R) \;\geq\; \mathrm{kdim}(S)$$

Conversely we start with a CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_n)$ of R. By the lying over theorem (8.32.(i)) there is a prime ideal $\mathfrak{q}_0 \in \mathrm{Spec}(S)$ such that $\mathfrak{q}_0 \cap R = \mathfrak{p}_0$. By the Going up Theorem (8.32.(iv)) we have $\mathfrak{p}_1 \in \mathbb{V}(\mathfrak{p}_0) = \mathbb{V}(\mathfrak{q}_0 \cap R) = \Sigma(\mathbb{V}(\mathfrak{q}_0))$. That is there is some $\mathfrak{q}_1 \in \mathbb{V}(\mathfrak{q}_0)$ such that $\mathfrak{p}_1 = \Sigma(\mathfrak{q}_1) = \mathfrak{q}_1 \cap R$. Thereby $\mathfrak{q}_1 \in \mathbb{V}(\mathfrak{q}_0)$ means $\mathfrak{q}_0 \subseteq \mathfrak{q}_1$. If we had $\mathfrak{q}_0 = \mathfrak{q}_1$ then of course $\mathfrak{p}_0 = \mathfrak{q}_0 \cap R = \mathfrak{q}_1 \cap R = \mathfrak{p}_1$ which is false. Hence we have $\mathfrak{q}_0 \subset \mathfrak{q}_1$ and continuing that way we can construct a CPI $(\mathfrak{q}_0, \ldots, \mathfrak{q}_n)$ of S with $\mathfrak{q}_k \cap R = \mathfrak{p}_k$ for any $k \in 0 \ldots n$. In particular we have found a CPI of the same length in S and thereby also conclude

$$\mathrm{kdim}(S) \;\geq\; \mathrm{kdim}(R)$$

(ii) Let $\mathfrak{a} := \mathfrak{u} \trianglelefteq_{\mathrm{i}} S$ be the ideal lying under $\mathfrak{u} \trianglelefteq_{\mathrm{i}} S$. As $S : R$ is an integral extension we know from

(8.29.(iv)) that $S/\mathfrak{u} : R/\mathfrak{a}$ is integral, too. Thus the claim is just another case of (i).

(iii) If $\text{height}(\mathfrak{u}) = \infty$, then there is nothing to prove. If $s := \text{height}(\mathfrak{u}) < \infty$ is finite, we pick up a CPI $(\mathfrak{q}_0, \ldots, \mathfrak{q}_s)$ of minimal length in S, that satisfies $\mathfrak{u} \subseteq \mathfrak{q}_s$. Then - as in the first part of (i) above - $(\mathfrak{q}_0 \cap R, \ldots, \mathfrak{q}_s \cap R)$ is a CPI in R, that satisfies $\mathfrak{u} \cap R \subseteq \mathfrak{q}_s \cap R$. There may be even shorter CPI in R with $\mathfrak{u} \cap R \subseteq \mathfrak{p}_r$ but at least we can conclude $\text{height}(\mathfrak{u} \cap R) \leq s = \text{height}(\mathfrak{u})$, as we have found a CPI of length s satisfying $\mathfrak{u} \cap R \subseteq \mathfrak{p}_s$.

(iv) By (iii) it remains to prove $\text{height}(\mathfrak{q}) \leq \text{height}(\mathfrak{q} \cap R)$. Note that $\mathfrak{p} := \mathfrak{q} \cap R$ is a prime ideal of R. If $\text{height}(\mathfrak{p}) = \infty$, there is nothing to prove hence let $r := \text{height}(\mathfrak{p}) < \infty$ be finite and pick up a CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$ in R, such that $\mathfrak{p}_r = \mathfrak{p}$ and r is minimal with this property. Recall that $\mathfrak{q} \cap R = \mathfrak{p}$, then by the Going-down theorem (8.72.(iii)) there is a CPI $(\mathfrak{q}_0, \ldots, \mathfrak{q}_r)$ in S lying over $(\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$, in particular $\mathfrak{q}_r = \mathfrak{q}$. That is $\text{height}(\mathfrak{q}) \leq r = \text{height}(\mathfrak{p}) = \text{height}(\mathfrak{q} \cap R)$. Thus we have both inequalities and hence equality.

□

Proof of (8.41):

(i) For (b) $\implies$ (a) let $m \in R[t]$ be a monic polynomial such that $m(ax) = 0$ and let $d := \deg(m)$. Now define another, not necessarily monic, polynomial over R, by letting

$$f(t) \;:=\; \sum_{k=0}^{d} m[k]a^k t^k$$

As $f[d] = a^d m[d] = a^d$ and $a \neq 0$ and $\text{NIL}(R) = 0$ we have $f[d] \neq 0$ such that $f \neq 0$. Then it is clear, that $f(x) = m(ax) = 0$ and hence we have shown, that x is algebraic over R.

Conversely, for (a) $\implies$ (b), let $f \in R[t]$ be a polynomial with $f \neq 0$ and $f(x) = 0$. Also let $d := \deg(f)$ and $a := f[d]$. Then $a \neq 0$ and as $f(x) = 0$ we also have $d \geq 1$. Again we define another polynomial, this time

$$m(t) \;:=\; t^d + \sum_{k=0}^{d-1} f[k]a^{d-1-k}t^k$$

Then $m(ax) = a^d x^d + f[d-1]a^0(ax)^{d-1} + \cdots + f[0]a^{d-1} = a^{d-1}(ax^d + f[d-1]x^{d-1} + \cdots + f[0]) = a^{d-1}f(x) = 0$. That is m is a monic polynomial satisfying $m(ax) = 0$ and hence ax is integral over R.

(ii) First of all, we have 0_S and $1_S \in \text{alg}(S : R)$, as $f(t) = t$ and $g(t) = t - 1_R$ satisfy $f(0_S) = 0_S$ and $g(1_S) = 1_S - 1_S = 0_S$ respectively. So it remains to verify, that for any x, $y \in \text{alg}(S : R)$ and any $r \in R$ we have $x + y$, xy and $rx \in \text{alg}(S : R)$ again.

Yet by (i) $x \in \text{alg}(S : R)$ means $ax \in \text{int}(S : R)$ for some $a \in R$ with $a \neq 0$. Likewise $by \in \text{int}(S : R)$ for some $b \in R$ with $b \neq 0$. Yet by (8.30.(vi)) we know, that $\text{int}(S : R)$ is a sub-ring of S. Thus we find $ab(xy) = (ax)(by) \in \text{int}(S : R)$ again. Now $ab \neq 0$, as R was assumed to be an integral domain, and hence $xy \in \text{alg}(S : R)$ by (i) again. In particular $rx = (r1_S)x \in \text{alg}(S : R)$. Also

$ab(x+y) = b(ax) + a(by) \in \mathrm{int}(S:R)$ such that $x+y \in \mathrm{alg}(S:R)$. Altogether $\mathrm{alg}(S:R)$ is a sub-algebra of S.

(iii) Let us assume that $S : R$ is algebraic, then we first prove the isomorphism property: Clearly $U^{-1}S \to \mathrm{quot}(S)$ given by $x/u \mapsto x/u$ is a well-defined homomorphism. And as S (and hence R) is an integral domain $x/u = y/v$ is equivalent to $vx = uy$. As this is true in $U^{-1}S$ and $\mathrm{quot}(S)$ alike, this also is the injectvity. For the surjectivity we are given any $x/y \in \mathrm{quot}(S)$, that is x, $y \in S$ with $y \neq 0$. Let us abbreviate $E := \mathrm{quot}(R) = U^{-1}R$, which is a field, and regard the extension $U^{-1}S : E$. As $S : R$ is algebraic we have y is algebraic over R. In particular $y/1 \in U^{-1}S$ is algebraic over E. But E is a field, so (8.30.(vii)) tells us, that $E[y/1]$ is a field, too. In particular $y'/u := (y/1)^{-1} \in E[y/1] \subseteq U^{-1}S$. Then it is clear, that $(xy')/u \mapsto x/y$, as $(xy')y = xu$.

Now abbreviate $E := \mathrm{quot}(R)$ (as we did before) and $F := \mathrm{quot}(S)$ and let us prove that $F : E$ is algebraic, too (under the assumption that $S : R$ is algebraic, still). As we have just seen: If $x/y \in F$ then there is some $s \in S$ and $u \in R$ with $u \neq 0$, such that $x/y = s/u$. Then s is algebraic over R, say $f(s) = 0$ for some $f \in R[t]$ with $f \neq 0$. Let $d := \deg(f)$ and

$$g(t) \;:=\; \sum_{k=0}^{d} \frac{f[k]u^k}{1} t^k \;\in\; E[t]$$

then $g(s/u) = f(s)/1 = 0$ and $\deg(g) = \deg(f) \geq 0$, such that $x/y = s/u$ is algebraic over E, as well. Altogether $F : E$ is algebraic.

Conversely, if we start with $F : E$ algebraic and consider any $s \in S$, then there is some polynomial $g \in E[t]$ such that $g \neq 0$ but $g(s/1) = 0$. Let $d := \deg(g)$ and for any $k \in 0 \ldots d$ let $g[k] = a_k/u_k$. Then take $u := u_0 u_1 \ldots u_d \in R$ with $u \neq 0$ such that $f := ug \in R[t]$. Then $f(s) = ug(s/1) = 0$, such that s is algebraic over R, too. As this is true for any $s \in S$ we have established $S : R$ to be algebraic.

(iv) If $T : R$ is algebraic, then any $z \in T$ is algebraic over R. In particular any $y \in S \subseteq T$ is algebraic over R, such that $S : R$ is algebraic, too. Also, as $R \subseteq S$ we find $z \in T$ to be algebraic over S, as well. And that is $T : S$ is algebraic, again.

Conversely let us abbreviate $E := \mathrm{quot}(R)$, $F := \mathrm{quot}(S)$ and $G := \mathrm{quot}(T)$. If now $S : R$ and $T : S$ are algebraic, then so are $F : E$ and $G : F$, according to (iii). But as E and F are fields, this is the same, as $F : E$ and $G : F$ being integral. Now use (8.31.(ii)) to find $G : E$ integral. In particular $G : E$ is algebraic, such that $T : R$ is algebraic again, by another dose of (iii).

(v) As $T : R$ is finitely generated, there are some $y_1, \ldots, y_n \in T$ such that $T = R[y_1, \ldots, y_n]$. And as $T : S$ if finite, there are some $x_1, \ldots, x_m \in T$, such that $T = \mathrm{Lh}_S\{ x_1, \ldots, x_m \}$. Combining these properties, we find some $a_{r,k} \in S$ and $b_{i,j,k} \in S$, such that for any $r \in 1 \ldots n$ and any $i, j \in 1 \ldots m$, we get

$$\begin{aligned} y_r &= \sum_{k=1}^{m} a_{r,k} x_k \\ x_i x_j &= \sum_{k=1}^{m} b_{i,j,k} x_k \end{aligned}$$

The sets $A := \{ a_{r,k} \mid r \in 1 \ldots n, k \in 1 \ldots n \}$ and $B := \{ b_{i,j,k} \mid i,j,k \in 1 \ldots m \} \subseteq S$ are finite, that is $S_0 := R[A \cup B]$ is finitely generated. But R is a noetherian ring, so the Hilbert Basis theorem tells us, that S_0 is noetherian, as well. So if we pick up any $u \in T = R[y_1, \ldots, y_n]$ there is some polynomial $g \in R[t_1, \ldots, t_n]$ such that $u = g(y_1, \ldots, y_n)$. The y_r are $R[A]$-linear combinations of the x_k. Thus $u = g(y_1, \ldots, y_n)$ is an $R[A]$-linear combination over products of the form $x_{\alpha(1)} \ldots x_{\alpha(s)}$. And by induction on s it is clear, that any product $x_{\alpha(1)} \ldots x_{\alpha(s)}$ can be written as an $R[B]$-linear combination of $\{ x_1, \ldots, x_m \}$. Altogether we can write u as an S_0-linear combination of $\{ x_1, \ldots, x_m \}$. And as this is true for any $u \in T$, we get

$$T \;=\; \mathsf{Lh}_{S_0}\{ x_1, \ldots, x_m \}$$

As S_0 is a noetherian ring and T is a finitely generated S_0-module, we get, that T is a noetherian S_0-module. As S is an intermediate ring it in particular is a submodule $S \leq_{\mathsf{m}} T$ and hence S is a finitely generated S_0 module. In particular $S : S_0$ is a finitely generated S_0-algebra (using the same generators). But $S_0 : R$ is finitely generated by construction, so combining this we find, that $S : R$ is finitely generated.

□

Proof of (8.45):

- We abbreviate $P := R[U]$ the intermediate ring generated by $U \subseteq S$ and begin by proving (i): In (a) $\iff$ (b) the definition $U \vdash x$ means that there is some polynomial $f \in P[t]$ such that $f \neq 0$ but $f(x) = 0$. But this is precisely the definition of x being algebraic overP and hence $x \in \mathsf{alg}(S : P)$. And (b) $\iff$ (c) has already been proved in (8.41.(i)) under the assumption $\mathrm{NIL}(R) = 0$ only. It remains to verify (b) $\iff$ (d): If $P[x] = R[U \cup \{ x \}]$ is algebraic over $P = R[U]$, then in particular x is algebraic over U such that we have (b). Conversely, as $P \subseteq S$ and S is an integral domain, P is an integral domain, too. Therefore by (8.41.(ii)) $\mathsf{alg}(S : P)$ is a sub-ring of S. In particular $P[x] \subseteq \mathsf{alg}(S : P)$. And this again means $P[x] : P$ is an algebraic ring extension.

- In order to prove (ii) we have to establish the properties (D1) to (D4) of a dependence relation. We can do (D1) to (D3) right away, but (D4) will require (iii). So we have to interject the proof of this. We start with (D1), that is: $U \vdash u$ for any $u \in U$. This is easy: Let $P := R[u]$, then is particular $u \in P$ and hence $f(t) := t - u \in P[t]$. Then f is monic and $f(u) = 0$, such that u is algebraic (even integral) over P. This means $U \vdash u$.

- Let us continue, with (D2), that is: If $U \vdash x$ then there is some finite subset $U_x \subseteq U$ such that $U_x \vdash x$ already:

 Let $P := R[U]$, then by definition $U \vdash x$ means, that there is some $f \in P[t]$ such that $f \neq 0$ but $f(x) = 0$. Let $d := \deg(f)$, then $f[d] \neq 0$ and $f[k] \in P = R[U]$ for any $k \in \mathbb{N}$. By construction of $R[U]$ this means, that for any k there is a finite subset $U_k \subseteq U$ such that $f[k] \in R[U_k]$. Now let

 $$U_x \;:=\; \bigcup_{k=0}^{d} U_k$$

 Then U_x is finite, as well, and as $U_k \subseteq U_x$ we have $f[k] \in R[U_x]$ for any $k \in 0 \ldots d$. Therefore

$f = f[d]t^d + \cdots + f[1]t + f[0] \in R[U_x][t]$ and as $f[d] \neq 0$ and $f(x) = 0$, by assumption we have found $U_x \vdash x$.

- For (D3) we are given two subsets $V, U \subseteq S$, such that $V \vdash U$ and $U \vdash x$. That is we have $V \vdash u$ for any $u \in U$. Then we need to show $V \vdash x$:

 By assumption we have $V \vdash u$, which is $u \in \mathrm{alg}(S : R[V])$ by (i), for any $u \in U$. That is we have $U \subseteq \mathrm{alg}(S : R[V])$. Clearly this means $U \cup V \subseteq \mathrm{alg}(S : R[V])$, as $V \subseteq \mathrm{alg}(S : R[V])$ is a given. As S is an integral domain and $R[V]$ is a sub-ring of S, it is an integral domain, too. Hence by (8.41.(ii)) $\mathrm{alg}(S : R[U])$ is a ring again and therefore $R[U \cup V] \subseteq \mathrm{alg}(S : R[V])$. That is the extension $R[U \cup V] : R[V]$ is algebraic.

 But we also have $U \vdash x$ such that x is algebraic over $R[U]$. In particular x is algebraic over $R[U \cup V]$ but then the entire set $U \cup V \cup \{ x \}$ is algebraic over $R[U \cup V]$. By (8.41.(ii)) we conclude, that $R[U \cup V \cup \{ x \}] : R[U \cup V]$ is an algebraic extension, again.

 Together we have that both $R[U \cup V \cup \{ x \}] : R[U \cup V]$ and $R[U \cup V] : R[V]$ are algebraic. But by (8.31.(iv)) this means, that $R[U \cup V \cup \{ x \}] : R[V]$ is algebraic. In particular x is algebraic over $R[V]$ and this finally is $v \vdash x$.

- Let us now prove (iii), before turning our attention to property (D4). In (a) $\Longrightarrow$ (b) we do not require U to be algebraic independent: We have $U \vdash x$, but by property (D2) it suffices to regard a finite set $U = \{ u_1, \ldots, u_n \}$ for this. Then $U \vdash x$ yields a polynomial $f \in P[t]$ (where $P := R[U]$ again) such that $f \neq 0$ but $f(x) = 0$. We write f in the following form

$$f \;=\; \sum_{k=0}^{d} f_k \, t^k$$

 for some $f_k \in P$ and $f_d \neq 0$. That is $f_k = g_k(u_1, \ldots, u_n)$ for some polynomials $g_k \in R[t_1, \ldots, t_n]$. Now define the polynomial

$$g \;:=\; \sum_{k=0}^{d} g_k(t_1, \ldots, t_n) \, t_{n+1}^k \;\in\; R[t_1, \ldots, t_n, t_{n+1}]$$

 As $f_d \neq 0$ we have $g_d \neq 0$ and hence $g \neq 0$. Yet we also have $g(u_1, \ldots, u_n, x) = f(x) = 0$, which means that $\{ u_1, \ldots, u_n, x \}$ is algebraic dependent. In particular $U \cup \{ x \}$ is algebraic dependent.

 Conversely assume U to be algebraic independent, but $U \cup \{ x \}$ to be algebraic independent. That is there is some polynomial $g \in R[t_1, \ldots, t_{n+1}]$ such that $g \neq 0$ but $g(u_1, \ldots, u_n, x) = 0$. Write g in the form

$$g \;:=\; \sum_{k=0}^{d} g_k(t_1, \ldots, t_n) \, t_{n+1}^k$$

 with $g_d \neq 0$. As U is algebraic independent $\{ u_1, \ldots, u_n \}$ is algebraic independent and hence $g_d \neq 0$ implies $g_d(u_1, \ldots, u_n) \neq 0$. Therefore, if we define

$$f(t) \;:=\; \sum_{k=0}^{d} g_k(u_1, \ldots, u_n) \, t^k \;\in\; P[t]$$

 we have $f \neq 0$ as $f[d] = g_d(u_1, \ldots, u_n) \neq 0$. Never the less $f(x) = g(u_1, \ldots, u_n, x) = 0$, such

that x is algebraic over $R[u_1, \ldots, u_n]$. In particular x is algebraic over $R[U]$, which is $U \vdash x$.

- It is time we concluded (ii) by proving property (D4): That is we have $U \vdash x$ but for some $u \in U$ we also have $U \setminus \{ u \} \nvdash x$. Then we need to show $\big(U \setminus \{ u \}\big) \cup \{ x \} \vdash u$.

 First of all, it suffices to regard finite U for this: From $U \vdash x$ we find a finite set $U_0 \subseteq U$, such that $U_0 \vdash x$, by (D2). Suppose we had $u \notin U_0$, then $U_0 \setminus \{ u \} = U_0$ such that $U_0 \setminus \{ u \} = U_0 \vdash x$ in contradiction to $U \setminus \{ u \} \nvdash x$. Thus we have $u \in U_0$ and $U_0 \setminus \{ u \} \nvdash x$. If we are now able to prove $\big(U_0 \setminus \{ u \}\big) \cup \{ x \} \vdash u$, then the claim follows immediately, as $U_0 \subseteq U$.

 In a next step we claim, that $\{ u \}$ is algebraically independent: Suppose not, then there was some polynomial $f \in R[t]$ with $f \neq 0$ but $f(u) = 0$. But this means u is algebraic over R and hence $\emptyset \vdash x$. In particular $\{ u \} \setminus \{ u \} \vdash x$, in contradiction to $U \setminus \{ u \} \nvdash x$. That is the following set is non-empty, as it contains $\{ u \}$ as an element:

$$\mathcal{Q} \;:=\; \{\, Q \subseteq U \mid u \in Q,\, Q \text{ is algebraically independent} \,\}$$

 Now choose some $Q \in \mathcal{Q}$ with a maximal number of elements. This is possible, as $Q \subseteq U$ and we only need to regard a finite U. Then we claim: $Q \vdash U$. To do this consider an arbitrary $s \in U$. If $s \in Q$, then we are done already, as $Q \vdash s$ by (D1). If $s \in U \setminus Q$ then $Q \subset Q \cup \{ s \}$. Thus, as $Q \in \mathcal{Q}$ is maximal we find, that $Q \cup \{ s \}$ is algebraically dependent. But as Q is alebraically independent we conclude $Q \vdash s$ from (iii). Altogether $Q \vdash s$ for any $s \in U$ and hence $Q \vdash U$.

 But from $Q \vdash U$ and $U \vdash x$ we conclude $Q \vdash x$ by (D3). Suppose we had $Q \setminus \{ u \} \vdash x$ then, as $Q \subseteq U$, we also had $U \setminus \{ u \} \vdash x$, which is untrue. Thus we have found a set $Q \subseteq U$ with the following properties

 (1) $Q \vdash x$

 (2) $Q \setminus \{ u \} \nvdash x$

 (3) Q is finite

 (4) Q is algebraically independent

 Let $Q = \{ q_1, \ldots, q_n \}$ and by renumbering we may also assume $u = q_1$. Then (1) turns into $\{ q_1, \ldots, q_n \} \vdash x$ and (2) turns into $\{ q_2, \ldots, q_n \} \nvdash x$. Using (iii) again this can be turned into:

 (1') $\{ q_1, \ldots, q_n, x \}$ is algebraically dependent

 (2') $\{ q_2, \ldots, q_n, x \}$ is algebraically independent

 repsectively. By (2') $Q' := \{ q_2, \ldots, q_n, x \}$ satisfies the prerequisite of (iii), so we can conclude $Q' \vdash q_1$ from (1'). But this is precisely $\big(Q \setminus \{ u \}\big) \cup \{ x \} = Q' \vdash u$.

- Now for (iv): In (a) $\implies$ (b) we may assume $k = 1$, for ease of notation. Let $P := R[u_2, \ldots, u_n]$ and suppose $f \in P[t]$ is a polynomial with $f(u_1) = 0$. Let $d \geq \deg(f)$, then for any $k \in 0 \ldots d$ we have $f[k] \in P$, that is $f[k] = g_k(u_2, \ldots, u_n)$ for some $g_k \in R[t_2, \ldots, t_n]$. Let

$$g(t_1, \ldots, t_n) \;:=\; \sum_{k=0} g_k(t_2, \ldots, t_n)\, t_1^k$$

Then $0 = f(u_1) = g(u_1, u_2, \ldots, u_n)$ and by assumption (a) this means $g = 0$. This is $g_k = 0$ and hence $f[k] = 0$ for any $k \in 0 \ldots d$. In turn $f = 0$ and hence $\{ u_2, \ldots, u_n \} \vdash u_1$ is untrue.

We prove (b) $\implies$ (c) by negation $\neg$ (c) $\implies$ $\neg$ (b): This is obvious: As for any $k \in 1 \ldots n$ we have $\{ u_1, \ldots, u_{k-1} \} \subseteq U \setminus \{ u_k \}$ the dependency $\{ u_1, \ldots, u_{k-1} \} \vdash u_k$ *non* (c) would also imply $U \setminus \{ u_k \} \vdash u_k$, which is *non* (b).

We close the circle, by (c) $\implies$ (a): Suppose there was some polynomial $f \in R[t_1, \ldots, t_n]$ such that $f \neq 0$, but $f(u_1, \ldots, u_n) = 0$ then we can choose k minimal, such that $f(u_1, \ldots, u_k) = 0$ for some $f \in R[t_1, \ldots, t_k]$ with $f \neq 0$. If we had $k = 1$ then u_1 would be algebraic over R, which is ruled out, as by (c) for $k = 1$ we have $\emptyset \nvdash u_1$. Therefore $k \geq 2$, such that we may write this polynomial, as

$$f(t_1, \ldots, t_k) \;=\; \sum_{i=0}^{d} f_i(t_1, \ldots, t_{k-1})\, t_k^i$$

with $f_d \neq 0$ and let $a_i := f_i(u_1, \ldots, u_{k-1}) \in P = R[u_1, \ldots, u_{k-1}]$. Now take $g(t) := a_d t^d + \cdots + a_1 t + a_0 \in P[t]$ then $g(u_k) = f(u_1, \ldots, u_k) = 0$. As k was minimal we have $a_d \neq 0$ and hence $g \neq 0$. But this would mean $\{ u_1, \ldots, u_{k-1} \} \vdash u_k$ in contradiction to (c).

□

Proof of (8.46):

(i) If (a) U is $\vdash$independent, then by definition we have $U \setminus \{ u \} \nvdash u$ for any $u \in U$. Suppose U was *not* algebraically independent, that is there is a finite subset $U_0 \subseteq U$, which is not algebraically independent. Hence we may choose a subset $\{ u_1, \ldots, u_n \} \subseteq U$ that is algebraically independent, but with a minimal number n of elements. So consider any polynomial $f \in R[t_1, \ldots, t_n]$ such that $f(u_1, \ldots, u_n) = 0$ for some $u_1, \ldots, u_n \in U$. Unless $f = 0$ there is some t_k occurring in f, for ease of notation, say $d := \deg_1(f) \geq 1$. Always the same idea: We write f in the form

$$f \;=\; \sum_{k=0}^{d} f_k(t_2, \ldots, t_n)\, t_1^k$$

for some $f_k \in R[t_2, \ldots, t_n]$ where $f_d \neq 0$. As $\{ u_2, \ldots, u_n \}$ contains fewer than n elements, this set is algebraically independent and hence $f_d(u_2, \ldots, u_n) \neq 0$. Note that $n = 1$ is not a problem, in this case $f_d \neq 0 \in R$ already. Therefore $g(t) := f(t, u_2, \ldots, u_n) \in P[t]$ is a non-zero polynomial over $P = R[u_2, \ldots, u_n] \subseteq R[U \setminus \{ u_1 \}]$ such that $g(u_1) = 0$. This contradicts $U \setminus \{ u_1 \} \nvdash u_1$ and hence we conclude, that U *is* algebraically independent.

Let us commence, with (b) $\implies$ (c): That is we regard the evaluation homomorphism ε from $R[t_u \mid u \in U]$ to $R[U]$, that is defined by expansion of $\varepsilon(t_u) := u$

$$\varepsilon \,:\, R[t_u \mid u \in U] \to R[U] \,:\, t_u \mapsto u$$

By definition of $R[U]$ as the sub-ring generated by U this homomorphism is surjective. And $\varepsilon(f) = 0$ means $f(u_1, \ldots, u_n) = 0$ for some $u_i \in U$ - those u_i such that t_{u_i} occurs in f. But as U is algebraically independent, so is $\{ u_1, \ldots, u_n \}$ and therefore $f = 0$. This is $\mathrm{kn}(\varepsilon) = 0$, such that ε is

injective. Hence ε is an isomorphism.

We come full circle (c) $\implies$ (a): Pick any $u \in U$, then we need to show $U \setminus \{ u \} \nvdash u$. If we had $U \setminus \{ u \} \vdash u$, then we already had $\{ u_2, \ldots, u_n \} \vdash u$ for some finite subset $\{ u_2, \ldots, u_n \} \subseteq U$. That is there, is a polynomial $g(t) \in R[u_2, \ldots, u_n][t]$ such that $g \neq 0$ but $g(u) = 0$. Say g is

$$g(t) \;=\; \sum_{k=0}^{d} g_k(u_2, \ldots, u_n)\, t^k$$

where $g_d(u_2, \ldots, u_n) \neq 0$. As ε is an isomorphism of R-algebras we can apply $\varepsilon^{-1} : u_i \mapsto t_i := t_{u_i}$. If we also let $t_1 := \varepsilon^{-1}(u)$, that is $t_1 := t_u$ then $g(u) = 0$ turns into

$$0 \;=\; \varepsilon^{-1}\big(g(u)\big) \;=\; \sum_{k=0}^{d} g_k(t_2, \ldots, t_n)\, t_1^k$$

But this is a polynomial in $R[t_2, \ldots, t_n][t_1]$. And the polynomial only is 0, iff all its coefficients $g_k(t_2, \ldots, t_k)$ are. In particular $g_d = 0$, but this contradicts $g_d(u_2, \ldots, u_n) \neq 0$. Thus $U \setminus \{ u \} \vdash u$ cannot occur and hence U is $\vdash$independent.

(ii) If $\langle U \rangle = \{ x \in S \mid U \vdash x \}$ is the set of elements of S, that are generated by U, under the relation of algebraic dependence, then by (8.45.(i)) we have $\langle U \rangle = \operatorname{alg}(S : R[U])$. But in fact $U \vdash x$ is precisely the definition of $x \in S$ being algebraic over $R[U]$. Hence $\langle U \rangle = S$ is the same, as $\operatorname{alg}(S : R[U]) = S$, which is the same as $S : R[U]$ being an algebraic extension.

(iii) (a) contains: U is $\vdash$independent and $U \vdash$generates S. Due to (i) and (ii) respectively, this translates into U is algebraically independent and $S : R[U]$ is algebraic. And this is precisely the sitation we called (b): U is a transcendence basis of $S : R$.

(iv) As in (ii) we have $\langle U \rangle = \operatorname{alg}(S : R[U])$ and want to show $\langle U \rangle = \langle U' \rangle$ that is $\operatorname{alg}(S : R[U]) = \operatorname{alg}(S : R[U'])$. By assumption we have $R[U'] \subseteq R[U]$ and thereby $\operatorname{alg}(S : R[U]) \supseteq \operatorname{alg}(S : R[U'])$. For the converse inclusion we regard any $x \in \overline{U} := \operatorname{alg}(S : R[U])$ and need to show $x \in \operatorname{alg}(S : R[U'])$. By definition $\overline{U} : R[U]$ is algebraic. But by assumption we also have, that $R[U] : R[U']$ is algebraic. Hence by (8.41.(iv)) $\overline{U} : R[U']$ is algebraic, too. That is $x \in \overline{U} \subseteq \operatorname{alg}(S : R[U'])$.

Together we have $\langle U \rangle = \langle U' \rangle$ and U' is independent, by assumption. Thus we can invoke the basis exchange theorem of dependence relations (3.57.(x)) to conclude that $V' := (V \setminus U) \cup U'$ is a basis. This means V' is a transcendence basis of $S : R$.

□

Proof of (8.48):

(vi) Items (i) to (v) are clear or have already been argued for in the example above. So we only prove (vi) and (vii) here: Let us first check, that U truly is algebraically independent, that is we consider some polynomial $f \in R[t_2, \ldots, t_n]$ such that $f(u_2, \ldots, u_n) = 0$. As $u_k = t_k + pA$ this is $f(u_2, \ldots, u_n) = f(t_2, \ldots, t_n) + pA = 0$. In turn we find some $q \in A$ such that $f = pq$.

Let $d := \deg_1(p)$ which is $d \geq 1$, by assumption. If we had $f \neq 0$ then also $q \neq 0$, as A is an integral domain and thereby $0 = \deg_1(f) = \deg_1(p) + \deg_1(q) \geq d \geq 1$. This is absurd, so we must have $f = 0$ and hence U is algebraically independent.

It remains to prove, that $S : R[U]$ is algebraic. Note that $S = R[U][u_1]$ and that the algebraic closure is an R-algebra, by (8.41.(ii)), as S is an integral domain (p is prime). Hence it suffices to prove, that u_1 is algebraic over $R[U]$. But as U is algebraically independent this is the same as $U \cup \{ u_1 \} = \{ u_1, u_2, \ldots, u_n \}$ being algebraically dependent - refer to (8.45.(iii)) for this. And this now is trivial: $p(u_1, \ldots, u_n) = p(t_1, \ldots, t_n) + pA = p + pA = 0 + pA$.

(vii) First of all any $u \in U$ is integral over $R[U']$, as it trivially satisfies a polynomial of the form $t^{m(u)} - u^{m(u)} \in R[U'][t]$. Then by (8.30.(iv)) $R[U] : R[U']$ is integral and hence algebraic. But by assumption $S : R[U]$ is algebraic, too, such that $S : R[U']$ is algebraic, by (8.41.(iv)) again. But U' is algebraically independent, too: Suppose we had $f(u_1^{m_1}, \ldots, u_n^{n_m}) = 0$ for some polynomial $f \in R[t_1, \ldots, t_n]$. Then define $g := f(t_1^{m_1}, \ldots, t_n^{n_m})$ to get $g(u_1, \ldots, u_n) = 0$. This implies $g = 0$, as U is algebraically independent and hence $f = 0$.

□

Proof of (8.49):

(i) Let $\Delta := \det(A)$, then we start with $\Delta \neq 0$ and need to prove, that $\{ w_1, \ldots, w_n \}$ is a transcendence basis of $S : R$ again: Let $A^\#$ be the adjugate matrix of A, then by (4.63.(iii)) we have $A^\# A = A A^\# = \Delta \mathbb{1}_n$. Let us now regard the endomorphisms $\varphi := \varphi_A$ and $\varphi^\# := \varphi_{A^\#}$, that is

$$\varphi : R[t_1, \ldots, t_n] \to R[t_1, \ldots, t_n] : t_i \mapsto [At]_i$$

$$\varphi^\# : R[t_1, \ldots, t_n] \to R[t_1, \ldots, t_n] : t_i \mapsto [A^\# t]_i$$

then we obtain $\varphi^\# \varphi(t_i) = \varphi \varphi^\#(t_i) = \Delta t_i$ - according to (7.56). Let us prove that the map defined by $t_i \mapsto \Delta t_i$ is injective: That is we consider any polynomial $f \in R[t_1, \ldots, t_n]$ such that

$$0 \;=\; f(\Delta t_1, \ldots, \Delta t_n) \;=\; \sum_{\alpha \in \mathbb{N}^n} f[\alpha] \Delta^{|\alpha|}\, t^\alpha$$

As this is 0 we have $f[\alpha]\Delta^{|\alpha|} = 0$ for any $\alpha \in \mathbb{N}^n$. But as R is an integral domain and $\Delta \neq 0$ by assumption, this means $f[\alpha] = 0$. And as this is true for any α this is $f = 0$, again. Thus $\varphi_\Delta(t_i) := \Delta t_i$ is injective and as $\varphi^\# \varphi = \varphi_\Delta$ this implies, that φ is injective. Likewise $\varphi \varphi^\# = \varphi_\Delta$ makes $\varphi^\#$ injective, too, but we do not require this.

Als $\{ v_1, \ldots, v_n \}$ is algebraically independent the homomorphism $\varepsilon_v : R[t_1, \ldots, t_n] \to R[v_1, \ldots, v_n]$ of evaluation, that is defined by expansion of $\varepsilon_v : t_i \mapsto u_i$ is an isomorphism, due to (8.46.(i)). Now consider $\{ w_1, \ldots, w_n \}$ and any polynomial $f \in R[t_1, \ldots, t_n]$ such that $f(w_1, \ldots, w_n) = 0$. That is

$$\begin{aligned} 0 \;&=\; \sum_{\alpha \in \mathbb{N}^n} f[\alpha]\, w^\alpha \;=\; \sum_{\alpha \in \mathbb{N}^n} f[\alpha] \prod_{i=1}^n [Av]_i^{\alpha_i} \\ &=\; \varepsilon_v \left(\sum_{\alpha \in \mathbb{N}^n} f[\alpha] \prod_{i=1}^n [At]_i^{\alpha_i} \right) \;=\; \varepsilon_v \left(\varphi \left(\sum_{\alpha \in \mathbb{N}^n} f[\alpha]\, t^\alpha \right) \right) \end{aligned}$$

Note that we denote $t = (t_1, \ldots, t_n)$, $v = (v_1, \ldots, v_n)$ and $w = (w_1, \ldots, w_n)$ all the time. Then $f(w_1, \ldots, w_n) = 0$ turns into $\varepsilon_v(\varphi(f)) = 0$ and therefore $f = 0$, as ε_v is bijective and φ is injective. That is $\{ w_1, \ldots, w_n \}$ is algebraically independent, too. Also for any $i \in 1 \ldots n$ let

$$g_i(t) \;:=\; \Delta t - [A^{\#} w]_i \;\in\; R[w_1, \ldots, w_n][t]$$

As $A^{\#} w = A^{\#}(Av) = (A^{\#} A)v = \Delta v$ we have $\Delta v_i = [A^{\#} w]_i$ and thereby $g_i(v_i) = 0$. That is v_i is algebraic over $R[w_1, \ldots, w_n]$. Yet S is an integral domain and $R[w_1, \ldots, w_n] \subseteq S$ such that (8.41.(ii)) tells us that $R[v_1, \ldots, v_n]$ is algebraic over $R[w_1, \ldots, w_n]$. But by assumption S is algebraic over $R[v_1, \ldots, v_n]$, too. Hence S is algebraic over $R[u_1, \ldots, u_n]$ by (8.41.(iv)) and this means $\{ w_1, \ldots, w_n \}$ is a transcendence basis of $S : R$.

While this was a little demanding the converse direction is free for the taking: Suppose $\Delta = 0$, then we have to show, that $\{ w_1, \ldots, w_n \}$ is not a transcendence basis of $S : R$. We will prove that $\{ w_1, \ldots, w_n \}$ is algebraically dependent. In fact it already is linearly dependent! As $\det(A) = 0$ the row vectors $r_i := \mathrm{row}_i(A) \in R^n$ of A are linearly dependent, as we have seen in (4.65.(ii)). That is there is a non-trivial tuple $(a_1, \ldots, a_n) \neq 0 \in R^n$ such that $a_1 r_1 + \cdots + a_n r_n = 0$. Note that $w_i = [Av]_i = \langle r_i \mid v \rangle$ such that we can insert this equation into the scalar product with v:

$$0 \;=\; \langle 0 \mid v \rangle \;=\; \langle a_1 r_1 + \cdots + a_n r_n \mid v \rangle \;=\; a_1 w_1 + \cdots + a_n w_n$$

In particular, if we take the polynomial $f = a_1 t_1 + \cdots + a_n t_n \in R[t_1, \ldots, t_n]$, then $f \neq 0$, as one of the a_i is non-zero, but $f(w_1, \ldots, w_n) = 0$. That is $\{ w_1, \ldots, w_n \}$ is algebraically dependant.

(ii) Let us abbreviate $E := \mathrm{QUOT}(R)$ and $F := \mathrm{QUOT}(R)$. Then we first prove, that $V/1$ is algebraically independent over E: That is we consider a polynomial $g \in E[t_1, \ldots, t_n]$ such that for some $v_1, \ldots, v_n \in V$ we have $g(v_1/1, \ldots, v_n/1) = 0$. As g is a polynomial over E all its coefficients are of the form $g[\alpha] = a_\alpha / b_\alpha$ for some a_α, $b_\alpha \in R$ with $b_\alpha \neq 0$. Also, as g is a polynomial, the set $A := \{ \alpha \in \mathbb{N}^n \mid a_\alpha \neq 0 \}$ is finite. Now define

$$b \;:=\; \prod_{\alpha \in A} b_\alpha \;\in\; R$$

Then $b \neq 0$, as all the $b_\alpha \neq 0$ and R is an integral domain (since $R \subseteq S$). Also let $\widehat{b}_\alpha := b / b_\alpha \in R$, then $bg[\alpha] = b\, a_\alpha / b_\alpha = a_\alpha \widehat{b}_\alpha \in R$ and take a look at the polynomial

$$f \;:=\; \sum_{\alpha \in A} a_\alpha \widehat{b}_\alpha \, t^\alpha \;\in\; R[t_1, \ldots, t_n]$$

Then it is clear, that $0 = bg(v_1/1, \ldots, v_n/1) = \sum_\alpha bg[\alpha] v^\alpha / 1 = \sum_\alpha a_\alpha \widehat{b}_\alpha v^\alpha / 1 = f(v_1, \ldots, v_n)/1$. That is $f(v_1, \ldots, v_n) = 0$ and as V is algebraically independent, this implies $f = 0$. This means $a_\alpha \widehat{b}_\alpha = 0$ for any $\alpha \in A$. But as both a_α and $\widehat{b}_\alpha \neq 0$ are non-zero, this can only mean $A = \emptyset$. And this is $g = 0$. Hence $V/1$ is algebraically independent, as well.

It remains to prove, that $F : E[V]$ is algebraic: That is we consider any $x/y \in F$, hence x, $y \in S$

with $y \neq 0$. As $S : R[U]$ is algebraic, there is some polynomial $f(t) \in R[V][t]$ such that $f \neq 0$, but $f(x) = 0$. Say $d := \deg(f)$, then we define the polynomial

$$g(t) \;:=\; \sum_{k=0}^{d} \frac{f[k]y^k}{1} t^k \;\in\; E[V/1][t]$$

Then it is clear, that $g(x/y) = \sum_k (f[k]y^k/1)(x^k/y^k) = \sum_k f[k]x^k/1 = f(x)/1 = 0$. And as $f[d] \neq 0$ and $y \neq 0$ we also have $g[d] = f[d]y^d \neq 0$ such that $g \neq 0$. That is x/y is algebraic over $E[V/1]$ (even over $R[V/1]$). As this is true for any $x/y \in F$ the whole extension $F : E[V/1]$ is algebraic and altogether $V/1$ is a transcendence basis of $F : E$.

(iii) By assumption $S : R[V]$ and $R : Q[U]$ are algebraic, that is any $r \in R$ is algebraic over $Q[U]$. In particular any $r \in R$ is algebraic over the larger ring $Q[U \cup V]$. Also any $v \in V$ is algebraic (even integral) over $Q[U \cup V]$. That is we have found

$$R \cup V \quad \subseteq \quad \mathrm{alg}\big(S : Q[U \cup V]\big)$$

Yet the algebraic closure $\mathrm{alg}(S : Q[U \cup V])$ is a Q-sub-algebra of S, by (8.41.(ii)), such that $R[V] \subseteq \mathrm{alg}(S : Q[U \cup V])$. That is $R[V] : Q[U \cup V]$ is algebraic. Now as $S : R[V]$ is algebraic, too, we conclude that $S : Q[U \cup V]$ is algebraic, according to (8.41.(iv))

It remains to prove that $U \cap V = \emptyset$ and that $U \cup V$ is algebraically independent. Both will be apparent from the following reasoning: Suppose we had some polynomial $f \in Q[s_1, \ldots, s_m, t_1, \ldots, t_n]$ such that for some $u_i \in U$ and some $v_j \in V$ would yield $f(u_1, \ldots, u_m, v_1, \ldots, v_n) = 0$. Then we would write this term in the form

$$f(u_1, \ldots, u_m, v_1, \ldots, v_n) \;=\; \sum_{\beta \in \mathbb{N}^n} f_\beta(u_1, \ldots, u_m)\, v^\mu$$

That is we have a polynomial term over $Q[U]$ that turns $v_1, \ldots, v_n$ to zero. But by assumption V is algebraically independent over R and $Q[U] \subseteq R$. Thus we conclude $f_\beta(u_1, \ldots, u_m) = 0$. Hereby $f_\beta \in Q[s_1, \ldots, s_m$ is a polynomial again. So as U is algebraically independent over Q, we conclude $f_\beta = 0$. Thus the entire $f = 0$ is zero.

Suppose there was some $x \in U \cap V$, then we could have taken $f(s,t) := s - t \in Q[s,t]$. Then $f \neq 0$ but $f(x,x) = 0$ which we have just proven to be impossible. So as $U \cup V$ is a transcendence basis and $U \cap V = \emptyset$ we conclude the formula for the transcendence degrees in the claim above.

□

Proof of (8.50):

(i) As ε is a surjective homomorphism of R-algebras, by construction, (b) in truth is equivalent, to ε being injective. And for a homomorphism this equivalent to $\mathrm{kn}(\varepsilon) \subseteq 0$. Explicitly this is the implication $f(u_1, \ldots, u_n) = 0 \implies f = 0$, for any polynomial $f \in R[t_1, \ldots, t_n]$. And this is property (a) - U being algebraically independent - already.

(ii) To say that $v_0 \in V$ is algebraic over $R[U \cup V \setminus \{ v_0 \}]$ means that v_0 satisfies a non-zero polynomial whose coefficients are in this intermediate ring

$$\sum_{k=0}^{d} g_k v_0^k \;=\; 0 \;\text{ where }\; g_k \in R[U \cup V \setminus \{ v_0 \}]$$

That is g_k is a polynomial expression over $U \cup V \setminus \{ v \}$ and as such only depends on finitely many variables $u_i \in U$ and $v_j \in V \setminus \{ v_0 \}$. And as we only have finitely many g_k the collection of this is finite again. Say $u = (u_1, \ldots, u_m) \in U^m$ and $v = (v_1, \ldots, v_n) \in V^n$ are these variables, that is $g_k = f_k(u_1, \ldots, u_m, v_1, \ldots, v_n)$ for some $f_k \in R[s_1, \ldots, s_m, t_1, \ldots, t_n]$. Inserting this the above expression turns into

$$\sum_{k=0}^{d} \sum_{\alpha \in \mathbb{N}^m} \sum_{\beta \in \mathbb{N}^n} f_k[\alpha, \beta]\, u^\alpha v^\beta v_0^k \;=\; 0$$

This is a polynomial expression in $\{ u_1, \ldots, u_m, v_0, v_1, \ldots, v_n \} \subseteq U \cup V$ over R. And as $g_d \neq 0$ we have $f_d \neq 0$ and hence there are some α and β with $f_d[\alpha, \beta] \neq 0$. That is $U \cup V$ is algebraically dependent over R.

(ii) If $U \cup V$ is algebraically dependent, then there are $u = (u_1, \ldots, u_m) \in U^m$ and $v = (v_1, \ldots, v_n) \in V^n$ such that there is a non-zero polynomial $f \in R[s_1, \ldots, s_m, t_1, \ldots, t_n]$ such that $f(u, v) = 0$. That is we have an expression of the form

$$f(u,v) \;=\; \sum_{\alpha \in \mathbb{N}^m} \sum_{\beta \in \mathbb{N}^n} f[\alpha, \beta]\, u^\alpha v^\beta \;=\; 0$$

Let us take $n \in \mathbb{N}$ to be the minimal minimal number such that there is such a combination $(u, v) \in U^m \times V^n$. Suppose we had $f[\alpha, \beta] = 0$ for all $\beta \neq 0$. Then this would be a polynomial relation $\sum_\alpha f[\alpha, 0] u^\alpha = 0$ containing u only. As U is algebraically independent this means $f[\alpha, 0] = 0$ for any $\alpha \in \mathbb{N}^m$, too. But then we had $f = 0$, which we did not. Thus there have to be some $\alpha_0 \in \mathbb{N}^m$ and some $\beta_0 \in \mathbb{N}^n$ such that $\beta_0 \neq 0$ and $f[\alpha_0, \beta_0] \neq 0$. Hence there is some $j \in 1 \ldots n$ such that the j-th component of β_0 is 1 at least. For ease of notation let us assume $j = 1$, that is β_0 is of the form $\beta_0 = (r, \beta_0')$ with $r \geq 1$. Then we expand f as a polynomial in $R[s_1, \ldots, s_m, t_2, \ldots, t_n][t_1]$ to find an expression of the form

$$0 \;=\; f(u,v) \;=\; \sum_{k=0}^{d} \left(\sum_{\alpha \in \mathbb{N}^m} \sum_{\beta' \in \mathbb{N}^{n-1}} f[\alpha, \beta]\, u^\alpha v^{\beta'} \right) v_1^k$$

Now for $\alpha = \alpha_0$ and $(r, \beta') = \beta_0$ we have $f[\alpha, \beta] \neq 0$. As n was minimal the corresponding expression in brackets is non-zero. But this is a polynomial expression in v_1 over $R[u_1, \ldots, u_m, v_2, \ldots, v_n]$. In particular v_1 is algebraic over $R[U \cup V \setminus \{ v_1 \}]$.

(iii) Let $\mathcal{Z} := \{ V \subseteq S \mid U \subseteq V,\, V \text{ is algebraically independent over } R \}$. As $U \in \mathcal{Z}$ we have $\mathcal{Z} \neq \emptyset$. Now suppose $(V_i) \subseteq \mathcal{Z}$ is a chain of algebraically independent sets in S, where $i \in I$, then take

$$V \;:=\; \bigcup_{i \in I} V_i$$

We claim, that V is algebraically independent, again: To do this it suffices to regard finitely many elements $\{ v_1, \ldots, v_n \} \subseteq V$. By construction $v_k \in V_{i(k)}$ for some $i(k) \in I$. As the V_i form a chain we may assume (by renumbering the v_i) that $V_{i(1)} \subseteq \ldots \subseteq V_{i(n)}$. Then we have $\{ v_1, \ldots, v_n \} \subseteq V_{i(n)}$. But as $V_{i(n)}$ is algebraically independent, so is $\{ v_1, \ldots, v_n \}$ and this is what we aimed for:

Hence we may invoke the lemma of Zorn to find a maximal element $U^* \in \mathcal{Z}$. By construction this U^* satisfies (1) and (2) and it only remains to prove (3): Consider any $s \in S$, if $s \in U^*$ then clearly s is algebraic over $R[U^*]$, as it satisfies the polynomial $t - s \in R[U^*][t]$. Otherwise, if $s \notin U^*$, then $U^* \subset U^* \cup \{ s \}$ is a truly larger set. By maximality of U^* this means that $U^* \cup \{ s \}$ is algebraically dependent over R. But by (ii) this means that s is algebraically dependent over $R[U^*]$. Thus in any case $s \in S$ is algebraic over $R[U^*]$ and this is property (3).

(iv) Let $V_0 := V \setminus U$ such that $V' = V_0 \cup U'$. We need to show that $S : R[V']$ is integral again. Any $v \in V_0$ is integral over $R[V_0]$, as it satisfies the polynomial $t - v_0$. As $R[V_0] \subseteq R[V']$ it also is integral over $R[V']$. Also any $u \in U$ is integral over $R[U']$, by assumption (2). And as $R[U'] \subseteq R[V']$, we see that u is integral over $R[V']$. That is we have

$$V \;=\; V_0 \cup U \;\subseteq\; \mathrm{int}(S : R[V'])$$

And as the integral closure is a sub-ring of S, by (8.30.(iv)), we find $R[V] \subseteq \mathrm{int}(S : R[V'])$. That means $R[V] : R[V']$ is an integral extension. But $S : R[V]$ is integral, too, such that with (8.31.(ii)) we conclude, that $S : R[V']$ is an integral extension, again.

(v) In this case we need to prove, that V' is algebraically independent. Suppose V' was not, then there are finitely many elements $u' = (u'_1, \ldots, u'_m) \in U'^m$ and $v = (v_1, \ldots, v_n) \in V_0^n$ such that for some non-zero polynomial $f \in R[s_1, \ldots, s_m, t_1, \ldots, t_n]$ we have

$$f(u, v) \;=\; \sum_{\alpha \in \mathbb{N}^m} \sum_{\beta \in \mathbb{N}^n} f[\alpha, \beta]\, u'^{\alpha} v^{\beta} \;=\; 0$$

Take $g_\beta := \sum_\alpha f[\alpha, \beta]\, u'^{\alpha} \in R[U']$. As U' is algebraically independent and there are some α, β with $f[\alpha, \beta] \neq 0$ we also get $g_\beta \neq 0$ for this β. Now we rewrite the above equation in the form

$$\sum_{\beta \in \mathbb{N}^m} g_\beta\, v^{\beta} \;=\; 0$$

That is V_0 is algebraically dependent over $R[U']$. But by property (2) we have $R[U'] \subseteq R[U]$, such that V_0 is algebraically dependent over $R[U]$. That is there are some $u = (u_1, \ldots, u_m) \in U^m$ and $w = (w_1, \ldots, w_n) \in V_0^n$ such that

$$\sum_{\beta \in \mathbb{N}^n} \left(\sum_{\alpha \in \mathbb{N}^m} f[\alpha, \beta]\, u^{\alpha} \right) w^{\beta} \;=\; 0$$

As the $\sum_\alpha f[\alpha, \beta]\, u^{\alpha} \neq 0$ are non-zero, there are some α, β with $f[\alpha, \beta] \neq 0$. And therefore we have a polynomial relation between elements in V. But this contradicts V being algebraically independent and hence V' has to be algebraically independent, too.

□

Proof of (8.43):

- Let us first prove $xy^kA \subseteq xy^kE + x^2y^kB$: By construction any element of $a \in A$ is of the form $a = f(x, xy, \ldots, xy^n)$ for some $n \in \mathbb{N}$ and some polynomial $f \in E[t_0, t_1, \ldots, t_n]$. Therefore

$$xy^k a \;=\; xy^k f(x, xy, \ldots, xy^n) \;=\; xy^k \sum_{\alpha \in \mathbb{N}^{n+1}} f[\alpha](x, xy, \ldots, xy^n)^\alpha$$

 For any multi-index $\alpha \in \mathbb{N}^{n+1}$ let us denote $\omega(\alpha) := 0 \cdot \alpha_0 + 1 \cdot \alpha_1 + \cdots + n \cdot \alpha_n$. Then we clearly have $(x, xy, \ldots, xy^n)^\alpha = x^{|\alpha|}y^{\omega(\alpha)}$ such that we are able to find $xy^ka \in xy^kE + x^2y^kB$ from

$$\begin{aligned} xy^k a \;&=\; xy^k \sum_{\alpha \in \mathbb{N}^{n+1}} f[\alpha]\, x^{|\alpha|}y^{\omega(\alpha)} \;=\; xy^k \left(f[0] + \sum_{\alpha \neq 0} f[\alpha]\, x^{|\alpha|}y^{\omega(\alpha)} \right) \\ &=\; xy^k \left(f[0] + x \sum_{\alpha \neq 0} f[\alpha]\, x^{|\alpha|-1}y^{\omega(\alpha)} \right) \;=\; xy^k f[0] + x^2y^k \sum_{\alpha \neq 0} f[\alpha]\, x^{|\alpha|-1}y^{\omega(\alpha)} \end{aligned}$$

- As this is true for any $a \in A$ we have $xy^kA \subseteq xy^kE + x^2y^kB$. For the ideals $\mathfrak{a}_k$ we defined this turns into the following inclusion

$$\mathfrak{a}_k \;=\; \sum_{j=0}^{k} xy^jA \;\subseteq\; \sum_{j=0}^{k} xy^jE + \sum_{j=0}^{k} x^2y^jB \;\subseteq\; x\,\mathrm{Lh}_E\{\,1, y, \ldots, y^k\,\} + x^2B$$

 Form this we see that $xy^{k+1} \in \mathfrak{a}_{k+1}$ is not contained in $\mathfrak{a}_k$. As as the $\mathfrak{a}_k$ form an ascending chain, by construction, we conclude that this chain is strictly ascending

$$\mathfrak{a}_0 \;\subset\; \mathfrak{a}_1 \;\subset\; \ldots \;\subset\; \mathfrak{a}_k \;\subset\; \ldots$$

 Assume A was finitely generated, as E is a field (and hence noetherian) then (2.42) would tell us, that A is noetherian, too. But as we have the chain above, this is not the case. This proves, that A is not finitely generated - even though it is contained in the noetherian E-algebra B.

- Clearly $\{\, x, xy \,\}$ is algebraically independent: If $f \in E[s,t]$ is any polynomial, such that $f(x, xy) = 0$ then we get $f = 0$ from the fact, that $\{\, x, y \,\}$ is algebraically independent and we then have

$$0 \;=\; f(x, xy) \;=\; \sum_{\alpha \in \mathbb{N}^2} f[\alpha]\, x^{|\alpha|}y^{\alpha_2}$$

 Also any xy^k is algebraic over $E[x, xy]$: Just take the polynomial $g_k(t) := x^{k-1}t - (xy)^k$ then $g_k(xy^k) = x^ky^k - (xy)^k = 0$. But B is an integral domain and these elements generate A. Therefore the entire extension $A : E[x, xy]$ is algebraic, due to (8.41.(ii)).

- Let us now prove the proposition in two steps: First we assume $B := E[x]$ to be the polynomial ring in one variable. If $A = E$, then $A = E[0]$ is finitely generated, already, so let us suppose $E \subseteq A$. Then take

$$n \;:=\; \min\{\, \deg(a) \mid a \in A \setminus E \,\}$$

and let $p \in A$ be a monic polynomial with $\deg(p) = n$. Then $\varepsilon : E[t] \twoheadrightarrow E[p] : f \mapsto f(p)$ is surjective, by definition. But it also has $\mathrm{kn}(\varepsilon) = 0$, as $\deg(p) = n \geq 1$, by (7.27.(ii)) and hence is injective, too. That is $E[p]$ is isomorphic to a polynomial ring in one variable, under ε and hence a PID. As $p \in A \subseteq B$ we may regard A and $B = E[x]$ as $E[p]$-modules under multiplication as scalar multiplication. And by (8.29.(vi)) $R[x]$ has the basis $\{ 1, x, \ldots, x^{n-1} \}$ as an $E[p]$-module. In particular $B = E[x]$ is a free, finitely genrated $E[p]$-module, where $E[p]$ is a PID. Then by (3.104.(i)) the $E[p]$-sub-module $A \leq_{\mathfrak{m}} B$ is free and finitely generated, again. So let $\{ a_1, \ldots, a_m \}$ be a basis of A as an $E[p]$-module (where $m \leq n$), then we clearly have $A = \mathrm{Lh}_{E[p]}\{ a_1, \ldots, a_m \} \subseteq E[p, a_1, \ldots, a_m] \subseteq A$. That is A is finitely generated.

- Now consider a general $B = E[b]$, then we have an epimorphism of algebras $\varepsilon : E[x] \twoheadrightarrow B$ defined by $\varepsilon(f) = f(b)$. As $A \subseteq B$ is a sub-algebra, so is $A_0 := \varepsilon^{-1}(A) \subseteq E[x]$. As we have seen above, A_0 then is finitely generated, say $A_0 = E[a_1, \ldots, a_m]$ for some $a_i \in A_0$. As ε is surjective, we have $A = \varepsilon(\varepsilon^{-1}(A)) = \varepsilon(A_0)$ and as this is a homomorphism of E-algebras we conclude, that A is finitely generated, as well, since

$$A \;=\; \varepsilon(A_0) \;=\; \varepsilon\big(E[a_1, \ldots, a_m]\big) \;=\; E\big[\varepsilon(a_1), \ldots, \varepsilon(a_m)\big]$$

□

Proof of (8.33):
By (8.10(iii)) there is a finite ring extension $T : S$ such that the structural hohomorphism $\beta : S \hookrightarrow T$ is injective and p and q split over T. That is there are u_i and $v_j \in T$, such that

$$\begin{aligned} p(t) &= \prod_{i=1}^{m} (t - u_i) \\ q(t) &= \prod_{j=1}^{n} (t - v_j) \end{aligned}$$

By assumption both p and q are monic and hence pq is monic, too. Also we have $(pq)(u_i) = p(u_i)q(u_i) = 0 \cdot q(u_i) = 0$. That is $u_i \in T$ satisfies pq and in particular, it is integral over $\overline{R}$. Yet by (8.30.(vi)) this means that u_i already is integral over R: $u_i \in \mathrm{int}(T : R)$. But as $\mathrm{int}(T : R)$ is an intermediate ring of $T : R$ also any polynomial expression $f(u_1, \ldots, u_m)$ where $f \in R[t_1, \ldots, t_m]$ is integral over R. By the theorem of Vieta (7.66) the coefficients of p are elementary symmetric polynomials in the roots u_i and we have just argued, that these are integral over R again

$$p[k] \;=\; (-1)^{m-k} s^{(m)}_{m-k}(u_1, \ldots, u_m) \;\in\; \mathrm{int}(T : R)$$

for any $k \in 0 \ldots m$. In particular $p[k] \in \mathrm{int}(T : R) \cap S$ and hence $p[k] \in \mathrm{int}(S : R) = \overline{R}$. Altogether we have $p \in \overline{R}[t]$ and $q \in \overline{R}[t]$ follows in exactly the same manner. □

Proof of (8.37):
As $x \in S$ is integral over R, there is some monic polynomial $n \in R[t]$ with $n(x) = 0$. Let $E := \mathrm{quot}(R)$ be the quotient field of R and consider $R \subseteq E$ as a subset, canonically. Then the null ideal

$$\mathfrak{v}_x \;:=\; \{ h \in E[t] \mid h(x) = 0 \} \;\trianglelefteq_{\mathfrak{i}}\; E[t]$$

is non-zero, as $n \in \mathfrak{v}_x$. Yet $E[t]$ is a PID and hence we may take $m_x \in E[t]$ to be the monic generator of this ideal $\mathfrak{v}_x = m_x E[t]$. As $n \in m_x E[t]$ there is some $g \in E[t]$ such that $n = g m_x$. Recall that both n and m_x are monic and then g has to be monic, too [as $1 = \mathrm{lc}(n) = \mathrm{lc}(g) \cdot \mathrm{lc}(m_x) = \mathrm{lc}(g)$]. Thus by the lemma of Gauss (8.33) we have g, $m_x \in \overline{R}[t]$, where $\overline{R} = \mathrm{int}(E : R)$. But R is a normal domain, that is $\overline{R} = R$ and therefore $m_x \in R[t]$.
It remains to verify, that m_x is the minimal polynomial of x: We have (1) m_x is monic, by construction. And (2) $m_x(x) = 0$, as $m_x \in \mathfrak{v}_x$. (3) Let now $f(x) \in R[t]$ be any polynomial with $f(x) = 0$: If $f = 0$ then $f = 0 \cdot m_x$ and hence $m_x \mid f$ is clear. Otherwise take $a := \mathrm{lc}(f)$ and consider $h := (1/a)f \in E[t]$. Then $h(x) = 0$ as well and thereby $h = g\mu_x$ for some $g \in E[t]$. By the same reasoning as before (h and m_x are monic), we get $g(x) \in R[t]$. And thereby we get $f = ah = agm_x$ and $ag \in R[t]$. That is $m_x \mid f$ in $R[t]$, which is required for m_x to be the minimal polynomial. □

Proof of (8.32):

(i) Let us first prove the following statement: Given any prime ideal $\mathfrak{q} \trianglelefteq_{\mathrm{i}} S$ the pull-back $\Sigma(\mathfrak{q}) = \mathfrak{q} \cap R$ is a prime ideal of R again. Formally that is the implication

$$\mathfrak{q} \in \mathrm{Spec}(S) \quad \Longrightarrow \quad \mathfrak{q} \cap R \in \mathrm{Spec}(R)$$

First of all $\mathfrak{q} \cap R = \alpha^{-1}(\mathfrak{q})$ is an ideal again, as α is a homomorphism of rings. Also, if a, $b \in R$ with $ab \in \mathfrak{q} \cap R$ then we have $\alpha(a)\alpha(b) = \alpha(ab) \in \mathfrak{q}$. But as $\mathfrak{q}$ is prime we have $\alpha(a) \in \mathfrak{q}$ or $\alpha(b) \in \mathfrak{q}$. But this again is $a \in \mathfrak{q} \cap R$ or $b \in \mathfrak{q} \cap R$, such that $\mathfrak{q} \cap R$ is prime again. In particular Σ is well-defined.

(ii) Next we deal with the following statement: Given any maximal ideal $\mathfrak{n} \trianglelefteq_{\mathrm{i}} S$ the pull-back $\Sigma(\mathfrak{n}) = \mathfrak{n} \cap R$ is a maximal ideal of R again. Formally that is the implication

$$\mathfrak{n} \in \mathrm{Smax}(S) \quad \Longrightarrow \quad \mathfrak{n} \cap R \in \mathrm{Smax}(R)$$

To do this, let us abbreviate $\mathfrak{m} := \mathfrak{n} \cap R \trianglelefteq_{\mathrm{i}} R$. Then we regard the ring extension $S/\mathfrak{n}$ over $R/\mathfrak{m}$. As $S : R$ is integral (8.29.(ii)) tells us, that

$$S\Big/_{\mathfrak{n}} : R\Big/_{\mathfrak{m}} \text{ is integral}$$

too, under the injective structural homomorphism $\overline{\alpha} : a + \mathfrak{m} \mapsto \alpha(a) + \mathfrak{n}$. Now, as $\mathfrak{n}$ is maximal, $S/\mathfrak{n}$ is a field. But $\overline{\alpha}$ is injective such that $R/\mathfrak{m}$ is a field, as well, according to (8.30.(viii)). But this again means $\mathfrak{m} = \mathfrak{n} \cap R$ is maximal, as well. In particular the restriction of Σ to the maximal spectra is well-defined, as well.

(ii) Conversely let $\mathfrak{n} \in \mathrm{Spec}(S)$ be a prime ideal, such that $\mathfrak{m} := \mathfrak{n} \cap R$ is a maximal ideal. Then we need to show, that $\mathfrak{n}$ is a maximal ideal of S. Again we regard

$$S\Big/_{\mathfrak{n}} : R\Big/_{\mathfrak{m}} \text{ is integral}$$

As $\mathfrak{m}$ is maximal, $R/\mathfrak{m}$ is a field. But as $\mathfrak{n}$ was assumed to be prime, $S/\mathfrak{n}$ is an integral domain. So by (8.30.(viii)) again, we find $S/\mathfrak{n}$ to be a field. This in turn means, that $\mathfrak{n}$ is a maximal ideal.

(i) We are now able to prove, that (under the assumption that $S : R$ is integral) Σ is surjective. That is we are given any prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ and need to find some prime ideal $\mathfrak{q} \trianglelefteq_{\mathrm{i}} S$, such that $\mathfrak{p} = \mathfrak{q} \cap R$. To do this let $U := R \setminus \mathfrak{p}$, which is multiplicatively closed, as $\mathfrak{p}$ is a prime ideal. As $S : R$ is integral (8.29.(iv)) tells us, that

$$U^{-1}S : U^{-1}R \text{ is integral}$$

too, under the structural isomorphism $U^{-1}\alpha(a) = a1_S/u$. Note that $U^{-1}R = R_{\mathfrak{p}}$ is a local ring with maximal ideal $\mathfrak{p}R_{\mathfrak{p}}$ according to (2.138). We thereby obtain a commutative diagram of homomorphisms of rings

$$\begin{array}{ccccccccc} \kappa_R & : & R & \to & U^{-1}R & : & a & \mapsto & \frac{a}{1} \\ & & \downarrow & & \downarrow & & & & \\ \kappa_S & : & S & \to & U^{-1}S & : & s & \mapsto & \frac{s}{1} \end{array}$$

where the vertical maps are given by $\alpha : a \mapsto a1_S$ and $U^{-1}\alpha : a/1 \mapsto a1_S/1$ respectively. From this explicit description it is clear, that this diagram truly commutes. As $S \neq 0$ and $0 \notin U$ we have $U^{-1}S \neq 0$ and hence we can choose any maximal ideal $\mathfrak{u} \trianglelefteq_{\mathrm{i}} U^{-1}S$. Then by (ii) above, $\mathfrak{u} \cap U^{-1}R$ is a maximal ideal ideal of $U^{-1}R = R_{\mathfrak{p}}$. But as this ring is local it only has one maximal ideal, such that we find

$$\mathfrak{u} \cap U^{-1}R \;=\; \mathfrak{p}R_{\mathfrak{p}}$$

Let $\mathfrak{q} := \kappa_S^{-1}(\mathfrak{u}) \trianglelefteq_{\mathrm{i}} S$. As $\mathfrak{u}$ is a prime ideal (even a maximal ideal) $\mathfrak{q}$ is a prime ideal of R, by (i) above. It remains to prove, that $\mathfrak{q} \cap R = \mathfrak{p}$, which is reduced to the following computation:

$$\begin{aligned} \mathfrak{q} \cap R \;&=\; \alpha^{-1}(\mathfrak{q}) \;=\; \alpha^{-1}\big(\kappa_S^{-1}(\mathfrak{u})\big) \;=\; \big(\kappa_S\alpha\big)^{-1}(\mathfrak{u}) \;=\; \big(U^{-1}\alpha\,\kappa_R\big)^{-1}(\mathfrak{u}) \\ &=\; \kappa_R^{-1}\big(U^{-1}\alpha\big)^{-1}(\mathfrak{u}) \;=\; \kappa_R^{-1}\big(\mathfrak{u} \cap U^{-1}R\big) \;=\; \kappa_R^{-1}\big(\mathfrak{p}R_{\mathfrak{p}}\big) \;=\; \mathfrak{p}R_{\mathfrak{p}} \cap R \;=\; \mathfrak{p} \end{aligned}$$

(ii) But from this we find that the restriction of Σ to the maximal spectra is surjective, too: Consider any maximal ideal $\mathfrak{m}$ of R, in particular $\mathfrak{m}$ is prime and hence by the surjectivity (i) of Σ, there is some prime ideal $\mathfrak{n}$ of S, such that $\mathfrak{n} \cap R = \mathfrak{m}$. Now, as $\mathfrak{m}$ is maximal, we find that $\mathfrak{n}$ is maximal, too, by the second item (ii), so the restriction of Σ is surjective, as well.

(iii) Let us denote $\mathfrak{p} := \mathfrak{u} \cap R$, then by assumption we also have $\mathfrak{p} = \mathfrak{v} \cap R$. As $S : R$ is integral, so is $(S/\mathfrak{u}) : (R/\mathfrak{p})$ under the injective structural homomorphism $\overline{\alpha}(a + \mathfrak{p}) = \alpha(a) + \mathfrak{u}$, by (8.29.(iv)). And by the correspondence theorem (1.71) $\mathfrak{v}/\mathfrak{u}$ is an ideal of $R/\mathfrak{u}$. Let us evaluate its pull-back

$$\mathfrak{v}\Big/_{\mathfrak{u}} \cap R\Big/_{\mathfrak{p}} \;=\; \{\, a + \mathfrak{p} \mid \alpha(a) + \mathfrak{u} \in \mathfrak{v}/\mathfrak{u} \,\} \;=\; \{\, a + \mathfrak{p} \mid \alpha(a) \in \mathfrak{v} \,\} \;=\; \mathfrak{v} \cap R\Big/_{\mathfrak{p}}$$

As $\mathfrak{v} \cap R = \mathfrak{p}$, too we find that $\mathfrak{v}/\mathfrak{u} \cap R/\mathfrak{p} = 0$. So by (8.29.(ii)) the pull-back is contained in the set of zero-divisors $\mathfrak{v}/\mathfrak{u} \subseteq \mathrm{zd}(R/\mathfrak{p})$. Yet $\mathfrak{p}$ is a prime ideal by assumption and hence $R/\mathfrak{p}$ does not have any zero-divisors. And thereby we get $\mathfrak{u} = \mathfrak{v}$ from

$$\mathfrak{v}\Big/_{\mathfrak{u}} \cap R\Big/_{\mathfrak{p}} \;=\; \{\, 0 + \mathfrak{p} \,\}$$

(iv) Consider any ideal $\mathfrak{b} \trianglelefteq_{\mathrm{i}} S$ and let $\mathfrak{a} := \mathfrak{b} \cap R$. As $S : R$ is integral, (8.29.(ii)) once again tells us

$$S\big/_{\mathfrak{b}} : R\big/_{\mathfrak{a}} \text{ is integral}$$

under the injective structural homomorphism $\overline{\alpha} : a + \mathfrak{a} \mapsto \alpha(a) + \mathfrak{b}$. Thereby we get from (i), that $\overline{\Sigma} := \operatorname{Spec}(\overline{\alpha})$ is surjective. Now take a look at the following diagram

$$\begin{array}{rcccc} \overline{\Sigma} & : & \operatorname{Spec}(S/\mathfrak{b}) & \twoheadrightarrow & \operatorname{Spec}(R/\mathfrak{a}) \\ & & \updownarrow & & \updownarrow \\ \Sigma & : & \mathbb{V}(\mathfrak{b}) & \to & \mathbb{V}(\mathfrak{a}) \end{array}$$

where the vertical maps are $\mathfrak{q} \mapsto \mathfrak{q}/\mathfrak{b}$ and $\mathfrak{p} \mapsto \mathfrak{p}/\mathfrak{a}$ respectively. These are bijective, due to the correspondence theorem (1.71). And if $\mathfrak{q}$ is a prime ideal of S, with $\mathfrak{b} \subseteq \mathfrak{q}$, then it is clear that $\mathfrak{a} = \mathfrak{b} \cap R \subseteq \mathfrak{q} \cap R = \Sigma(\mathfrak{q})$. Hence the lower row of this diagram is well defined, too. This diagram is commutative, as we find

$$\begin{aligned} \overline{\Sigma}\left(\mathfrak{q}\big/_{\mathfrak{b}}\right) &= \overline{\alpha}^{-1}\left(\mathfrak{q}\big/_{\mathfrak{b}}\right) = \left\{ a + \mathfrak{a} \;\middle|\; \alpha(a) + \mathfrak{b} \in \mathfrak{q}\big/_{\mathfrak{b}} \right\} \\ &= \{\, a + \mathfrak{a} \mid \alpha(a) \in \mathfrak{q} \,\} = {}^{\alpha^{-1}(\mathfrak{q})}\big/_{\mathfrak{a}} = {}^{\Sigma(\mathfrak{q})}\big/_{\mathfrak{a}} \end{aligned}$$

But as this diagram commutes, $\overline{\Sigma}$ is surjective and the vertical maps even are bijective, we conclude that the bottom line $\Sigma : \mathbb{V}(\mathfrak{b}) \twoheadrightarrow \mathbb{V}(\mathfrak{a})$ is surjective, as well. And this is $\Sigma(\mathbb{V}(\mathfrak{b})) = \mathbb{V}(\mathfrak{a})$.

(v) If $\mathfrak{q} \in \Sigma^{-1}(\mathfrak{p})$, then $\mathfrak{p} = \Sigma(\mathfrak{q}) = \mathfrak{q} \cap R$. Then we get $\mathfrak{p}S = (\mathfrak{q} \cap R)S \subseteq \mathfrak{q}$ from (8.15). And as there is some $\mathfrak{q}$ with $\mathfrak{p} = \mathfrak{q} \cap R$ the same proposition implies $\mathfrak{p} = (\mathfrak{p}S) \cap R$. It remains to prove the minimality: Consider any prime ideal $\mathfrak{q}' \trianglelefteq_{\mathrm{i}} S$ such that $\mathfrak{p}S \subseteq \mathfrak{q}' \subseteq \mathfrak{q}$, then the pull-backs inherit these inclusions

$$\mathfrak{p} = (\mathfrak{p}S) \cap R \subseteq \mathfrak{q}' \cap R \subseteq \mathfrak{q} \cap R = \mathfrak{p}$$

such that $\mathfrak{q}' \cap R = \mathfrak{q} \cap R$ and $\mathfrak{q}' \subseteq \mathfrak{q}$. But according to (iii) this implies $\mathfrak{q}' = \mathfrak{q}$, as claimed.

(i) It remains to prove, that in case S is a noetherian ring, Σ has finite fibres only. We postponed this, as it requires (v): There we have seen that those $\mathfrak{q} \in \operatorname{Spec}(S)$ that satisfy $\mathfrak{q} \cap R = \mathfrak{p}$ are minimal over $\mathfrak{p}S$. But by (2.45.(iv)) $\mathbb{V}(\mathfrak{p}S)_*$ is a finite set and hence $\Sigma^{-1}(\mathfrak{q})$ is finite, too.

□

Proof of (8.51):

- Pick up the variables x_1 to x_n in another polynomial ring $E[x_1, \ldots, x_n]$. Then by (7.57.(iii)) there are some numbers $1 \leq m_2 \leq \cdots \leq m_n$ (that can be given explicitly) and some $a \in E$ with $a \neq 0$, such that the polynomial

$$ag\big(x_1, x_2 + x_1^{m_1}, \ldots, x_n + x_1^{m_n}\big) \in E[x_2, \ldots, x_n][x_1]$$

is monic, if we regard it, as a polynomial in x_1 over $E[x_2, \ldots, x_n]$. Suppose we are able, to prove the claims for $g_1 := ag$, then the claim remains true for general polynomials g: Let $b := a^{-1}$ such that $g = bg_1$. (1) If $\{\, g_1, z_2, \ldots, z_n \,\}$ is algebraically independent then $\{\, bg_1, z_2, \ldots, z_n \,\}$ is

algebraically independent, too, as $x_1 \mapsto bx_1$ and $x_i \mapsto x_i$ for $i \in 2 \dots n$ induces an automorphism on $E[x_1, \dots, x_n]$. (2) $E[bg_1, z_2, \dots, z_n] = E[g_1, z_2, \dots, z_n] = P$ such that this statement is unchanged. (3) Also $gP = g_1P$ and $gA = g_1P$, such that (3) is unchanged, too. Thus if we start with g_1 then the above is a monic polynomial, and hence we may assume $a = 1$, in the following.

- As in the claim, let us define $z_i := t_i - t_1^{m_i} \in A$ for any $i \in 2 \dots n$ (that is $t_i = z_i + t_1^{m_i}$) and consider the evaluation homomorphism $\varepsilon : E[x_1, \dots, x_n] \to A$, defined by $\varepsilon(x_1) := t_1$ and $\varepsilon(x_i) := z_i$ for $i \in 2 \dots n$. Then we get

$$\begin{aligned} \varepsilon\Big(g\big(x_1, x_2 + x_1^{m_1}, \dots, x_n + x_1^{m_n}\big)\Big) &= g\big(t_1, z_2 + t_1^{m_1}, \dots, z_n + t_1^{m_n}\big) \\ &= g\big(t_1, t_2, \dots, t_n\big) \;=\; g \;\in\; A \end{aligned}$$

 On the other hand this is a monic polynomial in t_1 over the ring $P_2 := E[z_2, \dots, z_n]$. Let us define $h_2(t) \in P_2[t]$ to be this polynomial in t, that is we denote

$$h_2(t) \;:=\; g\big(t, z_2 + t^{m_1}, \dots, z_n + t^{m_n}\big) \;\in\; P_2[t]$$

 Then we have just seen, that $h_2(t_1) = g$. Now define $z_1 := g \in A$ and $h(t) := h_2(t) - z_1 \in P[t]$, where $P := E[z_1, z_2, \dots, z_n]$. Then by construction we have

$$h(t_1) \;=\; h_2(t_1) - z_1 \;=\; g - g \;=\; 0$$

- Note that h still is a monic polynomial in t over P, that satisfies $h(t_1) = 0$. Its leading term is of degree $\deg(h_2) = \deg_1(g) + m_2\deg_2(g) + \dots + m_n\deg_n(g)$ and as $\deg(g) \geq 1$ this means $\deg(h) \geq 1$, as well [note, that $g \in P[t]$ is a constant polynomial, as $g \in P$]. That is $h \neq 0$ and hence $t_1 \in A$ is integral over P. Therefore $P[t_1] : P$ is an integral extension, by (8.30) (i) and (iii). As we clearly have $t_1 \in P[t_1]$ and for any $i \in 2 \dots n$ also $t_i = z_i + t_1^{m_i} \in P[t_1]$, we find $A = E[t_1, \dots, t_n] \subseteq P[t_1] \subseteq A$, that is $P[t_1] = A$. We conclude, that $A : P = P[t_1] : P$ is integral and finitely generated (by t_1 only. That is $A : P$ is a finite extension, by (8.30.(v)).

- Now by (8.49.(iii)) we have $\operatorname{trdeg}(A : E) = \operatorname{trdeg}(A : P) + \operatorname{trdeg}(P : E)$. Hereby $\operatorname{trdeg}(A : E) = n$, as $\{ t_1, \dots, t_n \}$ is a transcendence basis of $A : E$ and $\operatorname{trdeg}(A : P) = 0$ as this is an algebraic extension - refer to example (8.48). So this leaves us with $\operatorname{trdeg}(P : E) = n$ and we recall $P = E[z_1, z_2, \dots, z_n]$. As $\{ z_1, \dots, z_n \}$ algebraically generates P there is a subset $V \subseteq \{ z_1, \dots, z_n \}$ that is a transcendence basis of $P : E$ - this is (8.47.(i)) for $U = \emptyset$ and $W = \{ z_1, \dots, z_n \}$. But $\#V = \operatorname{trdeg}(P : E) = n = \#W$ such that $V = \{ z_1, \dots, z_n \}$ already was a transcendence basis, to begin with. Thus we have proved parts (1) and (2).

- Therefore $P = E[z_1, \dots, z_n]$ is isomorphic (as an E-algebra) to a polynomial ring $R = E[x_1, \dots, x_n]$ in n variables, where the isomorphism is induced by $x_i \mapsto z_i$ - refer to (8.46.(i)). But as $x_1R \trianglelefteq_{\mathfrak{i}} R$ is a prime ideal, this implies, that $z_1P \trianglelefteq_{\mathfrak{i}} P$ is a prime ideal, too. Recall that $A : P$ is integral. Hence by the lying-over-theorem (8.32.(i)) there is a prime ideal $\mathfrak{u} \trianglelefteq_{\mathfrak{i}} A$ such that

$$z_1P \;=\; \mathfrak{u} \cap P$$

 We now want to prove $z_1P = gA \cap P$, as $z_1 = g$ and we still need to finish part (2) of the claim.

As $z_1 = g \in gA$ and $z_1 \in P$ we clearly have $z_1 \in gA \cap P$ and thereby $z_1P \subseteq gA \cap P$, as $gA \cap P$ is an ideal of P. It remains to verify the converse inclusion $gA \cap P \subseteq z_1P$: We get $z_1A \subseteq \mathfrak{u}$ from $z_1A = (z_1P)A = (\mathfrak{u} \cap P)A \subseteq \mathfrak{u}$, which are true in any ring-extension, according to (8.15) and (8.18). And from this inclusion we also get $gA \cap P = z_1A \cap P \subseteq \mathfrak{u} \cap P = z_1P$. Altogether we have $gP = z_1P = gA \cap P$, which has been claimed, in (3).

□

Proof of (8.52):

- **Claim 1:** Let $(E, +, \cdot)$ be a field and $A := E[t_1, \ldots, t_n]$ be the polynomial ring in $n \in \mathbb{N}$ variables. Also let $\mathfrak{a} \trianglelefteq_{\mathrm{i}} A$ be a proper ideal $\mathfrak{a} \neq A$. Then there is $\{ z_1, \ldots, z_n \} \subseteq A$ an algebraically independent set and some $k \in 0 \ldots n$ such that for $P := E[z_1, \ldots, z_n]$ we get $A : P$ is finite and

$$\mathfrak{a} \cap P \quad = \quad z_1P + \cdots + z_kP$$

- Nota the proof is very technical, so let us give a sketch of what we are about to do: We start with some $g_1 \in \mathfrak{a}$, $g_1 \neq 0$ and find a transcendence basis $\{ g_1, z_1, \ldots, z_n \}$. Then we iterate (induction on n), choose $g_2 \in \mathfrak{a} \cap E[z_2, \ldots, z_n]$ with $g_2 \neq 0$ and find a transcendence basis $\{ g_2, y_3, \ldots, y_n \}$. Then $\{ g_1, g_2, y_3, \ldots, y_n \}$ is a transcendence basis of $A : E$ again. We will go on, that is pick $g_3 \in \mathfrak{a} \cap E[y_3, \ldots y_n]$ with $g_3 \neq 0$ and so on, until - at some point - $\mathfrak{a} \cap E[x_j, \ldots, x_n] = 0$, then we stop an let $k = n - j$. The notation will be a little different, however.

- **Proof of 1:** If $n = 0$, then $A = E$ and hence $\emptyset$ is a transcendence basis of $A : E$. In this case $P = E[\emptyset] = E = A$ and hence $[A : P] = 1$ is finite. The only proper ideal of $A = E$ is $\mathfrak{a} = 0$ and therefore $\mathfrak{a} \cap P = 0$, such that $k = 0$ does the trick. Thus $n = 0$ is just a weird special case.

 If $\mathfrak{a} = 0$, then we can take $z_i := t_i$ and $k := 0$. Then $P = E[t_1, \ldots, t_n] = A$ and $\mathfrak{a} \cap P = 0$, so (1) and (2) are satisfied trivially and $\mathfrak{a} \cap P = 0$ also is property (3). So in the following let us only consider the case $n \geq 1$ and $\mathfrak{a} \neq 0$:

- We will do this by induction on n: In case $n = 1$ we have $A = E[t_1]$, which is a PID. Hence $\mathfrak{a}$ is of the form $\mathfrak{a} = gA$ for some $g \neq 0$ and therefore we can invoke (8.51) to find $z_1 = g$ and $k = 1$. So let us commence with the induction step $n \geq 2$:

 Choose any $g \in \mathfrak{a}$ with $g \neq 0$. Then by (8.51) there is $\{ g, z_2, \ldots, z_n \} \subseteq A$ an algebraically independent set such that for $Z := E[g, z_2, \ldots, z_n]$ we have: $A : Z$ is a finite ring-extension and $gZ = gA \cap Z$. Now let $Z_0 := E[z_2, \ldots, z_n]$ and

$$\mathfrak{a}_0 \quad := \quad \mathfrak{a} \cap Z_0$$

 As $\{ z_2, \ldots, z_n \}$ is algebraically independent, as it is a subset of such a set. Therefore we have an isomorphism of from the polynomial ring $E[x_2, \ldots, x_n] \xrightarrow{\sim} Z_0$ induced by $x_i \mapsto z_i$. Hence we can apply the induction hypothesis to $\mathfrak{a}_0 \trianglelefteq_{\mathrm{i}} Z_0$ [to be precise we apply it to the isomorphic copy of $\mathfrak{a}_0$ in $E[x_2, \ldots, x_n]$ and transfer the result back into Z_0]. That is we find an algebraically independent

set $\{ y_2, \ldots, y_n \} \subseteq Z_0$ such that $Z_0 : Y_0$ is finite, where $Y_0 := E[y_2, \ldots, y_n]$. Also there is some $k \in 0 \ldots n$ such that for we have

$$\mathfrak{a}_0 \cap Y_0 \;=\; y_2 Y_0 + \cdots + y_k Y_0$$

- Let us summarize: (1) A is an integral domain, (2) $\{ g, z_2, \ldots, z_n \}$ is a transcendence basis of $A : E$, (3) $\{ y_2, \ldots, y_n \}$ is algebraically independent, (4) $Y_0 \subseteq Z_0$ and (5) $Z_0 : Y_0$ is finite and hence algebraic. That is all the requirements of the basis exchange theorem (8.46.(vi)) are satisfied and this makes $\{ g, y_2, \ldots, y_n \}$ another transcendence basis of $A : E$.

- Let $Y := E[g, y_2, \ldots, y_n]$ then we need to show, that $A : Y$ even is finite: By construction we have $Z = E[g, z_2, \ldots, z_n] = Y[z_2, \ldots, z_n]$. For one g is integral over Y, as even $g \in Y$. Now recall that $Z_0 : Y_0$ finite, and hence integral. In particular any z_i is integral over Y_0 and thereby over Y, too. Thus Z is finitely generated by integral elements over Y and hence finite $[Z : Y] < \infty$ by (8.30.(ii)). But $A : Z$ is finite, as well and hence we find, that $A : Y$ is finite by (8.7.(iv))

$$[A : Y] \;\leq\; [A : Z] \cdot [Z : Y] \;<\; \infty$$

- Y will take the role of P in the claim and we want to prove, that the algebraically independent set $\{ g, y_2, \ldots, y_n \} \subseteq A$ also satisfies the identity of $\mathfrak{a} \cap P$. By now we have $\mathfrak{a}_0 \cap Y_0 = y_2 Y_0 + \cdots + y_k Y_0$ and $\mathfrak{a} \cap Z = gA \cap Z$ and remains to prove

$$\mathfrak{a} \cap Y \;=\; gY + y_2 Y + \cdots + y_n Y$$

 We start with the inclusion from right to left. As $g \in \mathfrak{a}$ and $g \in Y$ we find $gY \subseteq \mathfrak{a} \cap Y$. Also, for any $i \in 2 \ldots n$ we have $y_i \in y_2 Y_0 + \cdots + y_n Y_0 = \mathfrak{a}_0 \cap Y_0 = \mathfrak{a} \cap Z_0 \cap Y_0 = \mathfrak{a} \cap Y_0 \subseteq \mathfrak{a} \cap Y$. As g and any y_i are contained in $\mathfrak{a} \cap Y$ and this is an ideal, we have $gY + y_2 Y + \cdots + y_n Y \subseteq \mathfrak{a} \cap Y$.

- For the converse inclusion we regard some $f \in \mathfrak{a} \cap Y$. For systematic reasons let $y_1 := g$ and write f as a polynomial in y_1 over Y_0

$$f \;=\; \sum_{k=0}^{d} f_k(y_2, \ldots, y_n)\, y_1^k \;\in\; Y_0[y_1]$$

 For $k \geq 1$ we can pull put one $y_1 = g$ and hence find a term gp (where p is the term in brackets, below) that is an element of Y. As $g \in \mathfrak{a}$ we also see that gp is contained in $\mathfrak{a}$ and hence $gp \in \mathfrak{a} \cap Y$

$$f \;=\; f_0(y_2, \ldots, y_n) + g \left(\sum_{k=1}^{d} f_k(y_2, \ldots, y_n)\, y_1^{k-1} \right)$$

 That is we have $f = f_0 + gp$, where $p \in Y$ and hence $gp \in \mathfrak{a} \cap Y$, as we have argued above. Also $f \in \mathfrak{a}$ such that $f_0(y_2, \ldots, y_n) = f - gp \in \mathfrak{a}$, too. Also $f_0(y_2, \ldots, y_n) \in Y_0$ such that we get $f_0(y_2, \ldots, y_n) \in \mathfrak{a} \cap Y_0 = y_2 Y_0 + \cdots + y_n Y_0$. Altogether that is f is contained in

$$f \;=\; f_0(y_2, \ldots, y_n) + gp \;\in\; y_2 Y_0 + \cdots + y_n Y_0 + gY$$

In particular $\mathfrak{a} \cap Y \subseteq gY + y_2Y + \cdots + y_nY$ such that we have the equality. Hence the induction step is completed: We have proved (1) that $\{ g, y_2, \ldots, y_2 \}$ is a transcendence basis of $A : E$ and (2) the identity above, for $\mathfrak{a} \cap Y$, where $Y = E[g, y_2, \ldots, y_n]$.

- **Claim 2:** Let $(E, +, \cdot)$ be a field and $A = E[t_1, \ldots, t_n]$ be the polynomial ring in $n \in \mathbb{N}$ variables. Also consider a chain $\mathfrak{a} \subseteq \mathfrak{a}_2 \subseteq \ldots \subseteq \mathfrak{a}_r \trianglelefteq_{\mathrm{i}} A$ of proper ideals in A, that is $\mathfrak{a}_r \neq A$, of length $r \in \mathbb{N}$. Then there are a set of algebraically independent elements $\{ z_1, \ldots, z_n \} \subseteq A$ and increasing numbers $0 \leq k(1) \leq k(2) \leq \cdots \leq k(r) \leq n$ such that $A : P$ is a finite ring-extension, where $P := E[z_1, \ldots, z_n]$, and for any $i \in 1 \ldots r$ we have the identity

$$\mathfrak{a}_i \cap P \;=\; z_1P + \cdots + z_{k(i)}P$$

- **Proof of 2:** This time, we use induction on r. If $r = 0$, then the claim is trivial: $\{ t_1, \ldots, t_n \} \subseteq A$ is algebraically independent and $A = E[t_1, \ldots, t_n]$ and that's all. The case $r = 1$ is claim 1 exactly, so we only need to regard $r \geq 2$: By induction hypothesis we have an algebraically independent set $\{ y_1, \ldots, y_n \} \subseteq A$ and some numbers $0 \leq k(1) \leq \cdots \leq k(r-1) \leq n$ such that $A : R$ is finite and for any $i \in 1 \ldots (r-1)$ we have

$$\mathfrak{a}_i \cap R \;=\; y_1R + \cdots + y_{k(i)}R$$

 where $R := E[y_1, \ldots, y_n]$. Now abbreviate $h := k(r-1)$, $Q := E[y_{h+1}, \ldots, y_n]$ and $\mathfrak{b} := \mathfrak{a}_r \cap Q$. As before Q is isomorphic to a polynomial ring $E[x_{h+1}, \ldots, x_n]$, as $\{ y_{h+1}, \ldots, y_n \}$ is algebraically independent, as the larger set $\{ y_1, \ldots, y_n \}$ is so, too. Therefore we can use claim 1 on $\mathfrak{b} \trianglelefteq_{\mathrm{i}} Q$ to find an algebraically independent set $\{ z_{h+1}, \ldots, z_n \} \subseteq Q$ and some $k \in h \ldots n$ such that $Q : P$ is finite, where $P := E[z_{h+1}, \ldots, z_n]$ we have

$$\mathfrak{a}_r \cap P \;=\; \mathfrak{b} \cap P \;=\; z_{h+1}P + \cdots + z_kP$$

 Recall, that (1) A is an integral domain, (2) $V := \{ y_1, \ldots, y_n \}$ is a transcendence basis of $A : E$, (3) $U' := \{ z_{h+1}, \ldots, z_n \}$ is algebraically independent, (4) for $P = E[U']$ and $Q = E[U]$ with $U := \{ y_{h+1}, \ldots, y_n \} \subseteq V$ we have $P \subseteq Q$ and (5) $Q : P$ is algebraic, as it even is a finite ring-extension. That is all the requirements of the basis exchange theorem (8.46.(iv)) are met and hence $(V \setminus U) \cup U' = \{ y_1, \ldots, y_h, z_{h+1}, \ldots, z_n \}$ is a transcendence basis of $A : E$, too.

- Now denote $R' := R[y_1, \ldots, y_h, z_{h+1}, \ldots, z_n] = P[y_1, \ldots, y_h]$. This will take the role of P in the claim, so we need to show that $A : R'$ is a finite ring-extension. The idea is the same, as in claim 1 before: We already know, that $A : R$ is finite, so let us prove, that $R : R'$ is finite, too: Note that by construction we have $R = R'[y_{h+1}, \ldots, y_n]$. Also for $h + 1 \leq j \leq n$ we have $y_j \in Q$ and $Q : P$ is finite. Hence y_j is integral over P (8.30.(iii)) and as $P \subseteq R'$ also over R'. That is R is generated by finitely many integral elements (y_j where $h + 1 \leq j \leq n$) and hence finite (8.30.(ii)). Then $A : R'$ is finite, as $[A : R'] \leq [A : R] \cdot [R : R'] < \infty$ ((8.7.(iv))).

- As we have found our candidate $\{ y_1, \ldots, y_h, z_{h+1}, \ldots, z_n \}$ for an algebraically independent set and already have $A : R'$ finite, it remains to prove that the identities for $\mathfrak{a}_i \cap R'$ are satisfied, for any $i \in 1 \ldots r$. Let us first consider $i \in 1 \ldots r-1$, the case $i = r$ will be the next step. Then we have

to prove

$$\mathfrak{a}_i \cap R' \;=\; y_1 R' + \cdots + y_{k(i)} R'$$

Consider any $j \in 1 \ldots k(i)$, then $y_j \in y_j R \subseteq \mathfrak{a}_i \cap R$ by the induction hypothesis (see above). That is $y_j \in \mathfrak{a}_i$. Also $y_j \in R'$ as $j \leq k(i) \leq k(r-1) = h$ by construction. That is we have $y_j \in \mathfrak{a}_i \cap R'$ and as this is true for any $j \leq k(i)$ we conclude

$$\mathfrak{a}_i \cap R' \quad \supseteq \quad y_1 P' + \cdots + y_{k(i)} R'$$

Conversely consider any $f \in \mathfrak{a}_i \cap R'$. Let us consider f as an element of the polynomial ring $f \in R' = E[y_1, \ldots, y_{k(i)}][x_{k(i)+1}, \ldots, x_n]$ where $x_j = y_j$ for $k(i) < j \leq h$ and $x_j = z_j$ for $h < j \leq n$ respectively. Then we can split f into

$$f \;=\; \sum_{\alpha \in \mathbb{N}^{k(i)}} \sum_{\beta \in \mathbb{N}^{n-k(i)}} f[\alpha, \beta]\, y^\alpha x^\beta \;=\; \sum_{\alpha \in \mathbb{N}^{k(i)}} \left(\sum_{\beta \in \mathbb{N}^{n-k(i)}} f[\alpha, \beta]\, x^\beta \right) y^\alpha$$

Thereby the terms in brackets $f_\alpha := \sum_\beta f[\alpha, \beta] x^\beta$ are contained in $E[x_{k(i)+1}, \ldots, x_n] \subseteq R'$. That is for any $j \in 1 \ldots k(i)$ we have $\deg_j(f_\alpha) = 0$ (or even $f_\alpha = 0$). Let us now spit this sum into $\alpha = 0$ and those $\alpha \in \mathbb{N}^{k(i)}$ with $\alpha \neq 0$

$$f \;=\; f_0 + \sum_{\alpha \neq 0} f_\alpha\, y^\alpha$$

If $\alpha \neq 0$ there is some $j \in 1 \ldots k(i)$ such that $\alpha_j \geq 1$. Hence we have $y_j \mid y^\alpha$ for this j. And altogether we find that the latter part $g = f - f_0$ is contained in

$$g \;:=\; \sum_{\alpha \neq 0} f_\alpha\, y^\alpha \;\in\; y_1 R' + \cdots + y_{k(i)} R'$$

As also any $y_j \in \mathfrak{a}_i$ by the inclusion, we already proved, we find $g \in \mathfrak{a}_i$, as well. But $f \in \mathfrak{a}_i$ is true by assumption, so we have $f_0 = f - g \in \mathfrak{a}_i$. Also $f_0 \in R' \subseteq R$ such that $f_0 \in \mathfrak{a}_i \cap R = y_1 R + \cdots + y_{k(i)} R$. Thus we either have $f_0 = 0$ or $\deg_j(f_0) \geq 1$ for some $j \in 1 \ldots k(i)$. But by construction of f_0 as an element of $f_0 \in E[x_{k(i)+1}, \ldots, x_n]$ we have $\deg_j(f_0) = 0$ for any $j \in 1 \ldots k(i)$ such that $f_0 = 0$ is the only viable possibility. That is $f = g$ and hence

$$f \;=\; \sum_{\alpha \neq 0} f_\alpha y^\alpha \;\in\; y_1 R' + \cdots + y_{k(i)} R'$$

- It remains to prove the identity of $\mathfrak{a}_r \cap R'$. Due to the very technical construction in which the transcendence basis $\{ y_1, \ldots, y_h, z_{h+1}, \ldots, z_n \}$ of $A : E$ features elements of different names, we have to prove the identity

$$\mathfrak{a}_r \cap R' \;=\; y_1 R' + \cdots + y_h R' + z_{h+1} R' + \ldots z_k R'$$

That is we took $k(r) := k \geq h = k(r-1)$. For $j \in 1 \ldots h$ we have $y_j \in \mathfrak{a}_{r-1} \subseteq \mathfrak{a}_r$ and $y_j \in R'$, as well such that $y_j R' \subseteq \mathfrak{a}_r \cap R'$. And for any $j \in h+1 \ldots k$ we have $z_j \in z_j P \subseteq \mathfrak{a}_r \cap P \subseteq \mathfrak{a}_r$ such

that $z_j \in \mathfrak{a}_r$ and $z_j \in R'$ make $z_j R' \subseteq \mathfrak{a}_r \cap R'$. Therefore we have the inclusion

$$\mathfrak{a}_r \cap R' \quad \supseteq \quad y_1 R' + \cdots + y_h R' + z_{h+1} R' + \ldots z_k R'$$

Conversely regard any $f \in \mathfrak{a}_r \cap R'$ again. As $R' = E[z_{h+1}, \ldots, z_n][y_1, \ldots, y_h]$ we decompose f (as above) according to this structure of R'. That is we write f as

$$f \;=\; \sum_{\alpha \in \mathbb{N}^h} \sum_{\beta \in \mathbb{N}^{n-h}} f[\alpha, \beta]\, y^\alpha z^\beta \;=\; \sum_{\alpha \in \mathbb{N}^h} \left(\sum_{\beta \in \mathbb{N}^{n-h}} f[\alpha, \beta]\, z^\beta \right) y^\alpha$$

Hereby $f_\alpha := \sum_\beta f[\alpha, \beta]\, z^\beta \in P$ as $P = E[z_{h+1}, \ldots, z_n]$. Again we split f into the component f_0 for $\alpha = 0$ and the rest g which contains all summands with $\alpha \neq 0$

$$f \;=\; f_0 + \sum_{\alpha \neq 0} f_\alpha\, y^\alpha$$

If $\alpha \neq 0$ then for some $j \in 1 \ldots h$ we have $\alpha_j \geq 1$ and therefore $y_j \mid y^\alpha$. That is $f_\alpha y^\alpha$ is contained in $y_1 P + \cdots + y_h P$ and in particular in $y_1 R' + \ldots y_h R'$. It remains to deal with f_0: As $g := f - f_0 \in y_1 R' + \ldots y_h R' \subseteq \mathfrak{a}_r \cap R' \subseteq \mathfrak{a}_r$ has already been proved, we have both $g \in \mathfrak{a}_r$ and $f \in \mathfrak{a}_r$ such that $f_0 = f - g \in \mathfrak{a}_r$ too. As $f_0 \in P$ by construction, we have $f_0 \in \mathfrak{a}_r \cap P = z_{h+1} P + \cdots + z_k P$, in particular $f_0 \in z_{h+1} R' + \cdots + z_k R'$. Therefore we have also found the converse inclusion, as

$$f \;=\; f_0 + g \;\in\; z_{h+1} R' + \cdots + z_k R' + y_1 R' + \ldots y_h R'$$

- **Claim 3:** The Noetherian Normalisation Theorem itself. That is we drop the restriction of A being a polynomial ring $A = E[t_1, \ldots, t_n]$ and consider any finitely generated E-algebra $A \neq 0$.

- **Proof of 3:** By assumption A is finitely generated, say $A = E[x_1, \ldots, x_m]$ for some $x_i \in A$. Then clearly we have an epimorphism of E-algebras from the polynomial ring $E[t_1, \ldots, t_m]$ onto A, induced by evaluating $t_i \mapsto x_i$

$$\pi \,:\, E[t_1, \ldots, t_m] \;\twoheadrightarrow\; A \,:\, t_i \mapsto x_i$$

Let $\mathfrak{b}_0 := \mathrm{kn}(\pi)$ and for any $i \in 1 \ldots r$ also $\mathfrak{b}_i := \pi^{-1}(\mathfrak{a}_i)$. Then $\mathfrak{b}_0 \subseteq \mathfrak{b}_1 \subseteq \ldots \mathfrak{b}_r$ is an ascending chain of ideals in $B := E[t_1, \ldots, t_m]$. Not much of a surprise: We use claim 2 on B with this chain of ideals. That is there are algebraically independent elements $\{ q_1, \ldots, q_m \} \subseteq B$ and numbers $0 \leq l(0) \leq l(1) \leq \cdots \leq l(r) \leq m$ such that $B : Q$ is finite, where $Q := E[q_1, \ldots, q_m] \subseteq B$ and for any $i \in 0 \ldots r$ we get

$$\mathfrak{b}_i \cap Q \;=\; q_1 Q + \cdots + q_{l(i)} Q$$

Now let $n := m - l(0)$ and for any $i \in 1 \ldots r$ also $k(i) := l(i) - l(0)$. For any $j \in 1 \ldots n$ also take $p_j := \pi(q_{j+l(0)}) \in A$ and $P := E[p_1, \ldots, p_n] \subseteq A$.

- For $j \leq l(0)$ we have $q_i \in q_i Q \subseteq \mathfrak{b}_0 = \mathrm{kn}(\pi)$ and hence $\pi(q_j) = 0$. And for $j > l(0)$ we have $\pi(q_j) = p_{j-l(0)} \in P$. As all p_i are covered $[q_{1+l(0)} \mapsto p_1$ until $q_m \mapsto q_n]$ we find $\pi(Q) = P$. Recall that $B : Q$ is finite $\pi : B \twoheadrightarrow A$ is surjective and as we have just seen $\pi(Q) = P$. Then (8.28) tells

us, that $A : P$ is a finite ring-extension, too.

- We will now prove, that $\pi : E[q_{1+l(0)}, \ldots, q_n] \to E[p_1, \ldots, p_n]$ is an isomorphism: The surjectivity is clear, as $q_{j+l(0)} \mapsto p_j$ and the p_j generate P. For the injectivity we first note, that

$$\mathrm{kn}(\pi) \cap Q \;=\; \mathfrak{b}_0 \;=\; q_1 Q + \cdots + q_{l(0)} Q \;\subseteq\; E[q_1, \ldots, q_{l(0)}]$$

 Thus if $q \in E[q_{1+l(0)}, \ldots, q_n]$ with $\pi(q) = 0$ then we have $q \in E[q_1, \ldots, q_{l(0)}]$, as well. The only elements that are contained in both sets are scalars $q \in E$. But then $0 = \pi(q) = q\pi(1_B) = q1_A$, as π is an E-algebra homomorphism. But E is a field and $A \neq 0$, by assumption. Thus we have $q = 0$ and therefore π is injective, when restricted to $E[q_{1+l(0)}, \ldots, q_n]$. As the elements $\{ q_1, \ldots, q_m \}$ are algebraically independent we see, that $\{ p_1, \ldots, p_n \}$ are algebraically independent, too, as any (polynomial) relation between them could be pulled back to a (polynomial) relation of the $\left\{ q_{1+l(0)}, \ldots, q_n \right\}$. But as this set is algebraically independent, there is no such relation.

- It remains to verify the identity for the ideals $\mathfrak{a}_i \cap P$. Recall that $\mathfrak{b}_i = \pi^{-1}(\mathfrak{a}_i) = \{ b \in B \mid \pi(b) \in \mathfrak{a}_i \}$ and for any $i \in 1 \ldots r$ we have $\mathfrak{b}_i \cap Q = q_1 Q + \cdots + q_{l(i)} Q$. We now have to verity

$$\mathfrak{a}_i \cap P \;=\; p_1 P + \cdots + p_{k(i)} P$$

 We now claim $\pi(\mathfrak{b}_i \cap Q) \subseteq \mathfrak{a}_i \cap P$: That is we regard some $q \in \mathfrak{b}_i \cap Q$. As $q \in \mathfrak{b}_i = \pi^{-1}(\mathfrak{a}_i)$ we have $\pi(q) \in \mathfrak{a}_i$. Also $q \in Q$ turns into $\pi(q) \in \pi(Q) = P$. That is $\pi(q) \in \mathfrak{a}_i \cap P$ and so we are done. Conversely $\pi(\mathfrak{b}_i \cap Q) \supseteq \mathfrak{a}_i \cap P$ is true as well: We start with any $p \in \mathfrak{a}_i \cap P$. As $\pi(Q) = P$, there is some $q \in Q$ with $\pi(q) = p$. Also we get $q \in \pi^{-1}(\mathfrak{a}_i) = \mathfrak{b}_i$ by construction. Thus we have $q \in \mathfrak{p}_i \cap Q$ and therefore $p = \pi(q) \in \pi(\mathfrak{p}_i \cap Q)$. Altogether we have

$$\pi\big(\mathfrak{b}_i \cap Q\big) \;=\; \mathfrak{a}_i \cap P$$

 But we also have $\pi(q_j) = 0$ for $1 \leq j \leq l(0)$ and $\pi(q_j) = p_{j-l(0)}$ for $l(0) < j < m$. And as also $\pi(Q) = P$ we find the identity for $\mathfrak{a}_i \cap P$ by an easy computation

$$\mathfrak{a}_i \cap P \;=\; \pi\big(\mathfrak{b}_i \cap Q\big) \;=\; \pi\left(\sum_{j=1}^{l(i)} q_j Q\right) \;=\; \sum_{j=1}^{l(i)} \pi\big(q_j\big) P \;=\; \sum_{j=l(0)+1}^{l(i)} p_{j-l(0)} P \;=\; \sum_{j=1}^{l(i)-l(0)} p_j P$$

 Recall that $k(i) = l(i) - l(0)$ such that we truly have $\mathfrak{a}_i \cap P = p_1 P + \cdots + p_{k(i)} P$. This is property (3) of the claim. We already have (1), that $\{ p_1, \ldots, p_n \}$ is algebraically independent and (2) that $A : P$ is finite. We are done, at long last.

□

Proof of (8.55):

- All the proofs are astoundingly simple, all we have to do is reap the harvest from previous propositions: For (b) $\implies$ (c) for example it suffices to note, that any finite extension $K : F$ already is algebraic, according to (8.30.(iii)). For (c) $\implies$ (a) we pick up any $z \in K$, that is algebraic over F. As F is a field z is integral over F. Then $F[z] : F$ is finite, by (8.30.(i)) such that $F[z] = F1_K$, by assumption. But this means $\mathrm{alg}(K : F) \subseteq F1_K$ and the converse inclusion is clear.

- Let us continue with (c) $\implies$ (d): As $\deg(f) \geq 1$ we can invoke (8.10.(iv)) to bring up a field K, such that $K : F$ is finite and f splits over K. That is f is of the form

$$f(t) \;=\; a\prod_{i=1}^{n}(t - z_i)$$

for some $z_i \in K$, where the identity is in $K[t]$. Thereby we see $n = \deg(f)$ by comparing the degrees of these terms. As $K : F$ is finite, assumption (c) tells us that $z_i = x_i 1_K$ for some $x_i \in F$. As $\alpha : F \hookrightarrow K : a \mapsto a1_k$ is injective, this also implies the following identity in $F[t]$

$$f(t) \;=\; a\prod_{i=1}^{n}(t - x_i)$$

- The implication (d) $\implies$ (e) is clear, just choose $x = x_1$ as a root. For (e) $\implies$ (f) we choose any $x \in F$ such that $p(x) = 0$. From this we get $t - x \mid p$, according to (7.54.(iii)). But as p is irreducible and $t - x$ is not a unit in $E[t]$, this means $p = a(t - x)$ for some $E[t]^* = E^*$. In particular $\deg(p) = 1$. This enables us to also prove (f) $\implies$ (a): Choose any $z \in \mathrm{alg}(K : F)$, as z is algebraic and F is a field (hence an UFD, hence normal), z admits a minimal polynomial m_x, according to (8.37). But $p := m_x$ is prime and hence irreducible. Thus by assumption (f) we have $\deg(m_x) = 1$. This means $m_x = t - a$ for some $a \in F$. But as $0 = m_x(x) = x - a1_K$ this implies $x = a1_K \in F1_K$. As this is true for any z we get $\mathrm{alg}(K : F) \subseteq F1_K$ and the converse implication is clear, again.

□

Proof of (8.56):
If $\mathfrak{m} \trianglelefteq_{\mathrm{i}} F[t]$ is a maximal ideal, then $\mathfrak{m} = pF[t]$ for some $p \in F[t]$, as $F[t]$ is an euclidean domain and hence a PID. And as any maximal ideal is prime, p is prime and hence irreducible. Conversely, if $p \in F[t]$ is irreducible, then choose a maximal ideal $\mathfrak{m}$ such that $pF[t] \subseteq \mathfrak{m}$. Choose $m \in F[t]$ such that $\mathfrak{m} = mF[t]$, then $pF[t] \subseteq mF[t]$ implies $m \mid p$. That is $p = mf$ for some $f \in F[t]$. As p is irreducible, we have m or $f \in F[t]^*$. If we had $m \in F[t]^*$ then $\mathfrak{m}$ would be the whole ring $F[t]$, in contradiction to $\mathfrak{m}$ being maximal. Thus we have $f \in F[t]^*$ and thereby $pF[t] = mF[t] = \mathfrak{m}$. That is $pF[t]$ is a maximal ideal.
Generally $t - a$ is irreducible, for any $a \in F$, because of $\deg(t - a) = 1$. Thus by the above $(t - a)F[t]$ is a maximal ideal of $F[t]$. Conversely a maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} F[t]$ is of the form $pF[t]$ for some irreducible p. But if F is algebraically closed, then by (8.55.(f)) $\deg(p) = 1$. That is $p = ut - v$ for some $u, v \in F$ with $u \neq 0$. By taking $a := u^{-1}v$ we get $(t - a)F[t] = u(t - a)F[t] = (ut - v)F[t] = \mathfrak{m}$. And hence we also have the identity of the maximal spectrum of $F[t]$. □

Proof of (8.57):

(i) As $R[t \mid A]$ is a free R-module, having the basis $\{\, t^\alpha \mid \alpha \in A \,\}$ we have $\dim(R[t \mid A]) = |A|$ and thereby we have proved the claim in remark (3.67) already.

(ii) By definition $R[t_i \mid i \in I]$ is just the polynomial ring $R[t \mid A]$ for the commutative monoid $A = \mathbb{N}^{\oplus I}$. So let us take a closer look at the cardinality of A: If I is finite, say $\#I = n$, then $A = \mathbb{N}^n$ and thereby $|A| = |\mathbb{N}|$, because of (0.38.(iv).(c)) or alternatively, by (0.35.(ii)). If I is infinite, then never

the less any $\alpha \in A$ only has finitely many non-zero entries, that is $A = \mathcal{F}_0(I, \mathbb{N})$ in the notation of (3.67). And thereby A can be mapped injectively into the set $\Omega(I \times \mathbb{N})$ of finite subsets of $I \times \mathbb{N}$

$$A \hookrightarrow \Omega(I \times \mathbb{N}) : \alpha \mapsto \{ (i, \alpha_i) \mid i \in I, \alpha_i \neq 0 \}$$

Then we can use items (v).(d) and (v).(b) of proposition (0.38) again, this time, as I is infinite, we get $|A| \leq |\Omega(I \times \mathbb{N})| = |I \times \mathbb{N}|$. If I is infinite we also have $|\mathbb{N}| \leq |I|$, such that in any case

$$|A| \leq \max\{ |\mathbb{N}|, |I| \}$$

Conversely $I \hookrightarrow A : i \mapsto \delta_i$ clearly is injective, such that $|I| \leq |A|$. And if we fix any $i \in I$ then $\mathbb{N} \hookrightarrow A : n \mapsto n\delta_i$ is another injective map, that also guarantees $|\mathbb{N}| \leq |A|$. Altogether we get $|A| = \max\{ |\mathbb{N}|, |I| \}$ and the rest is (i): From this we know $|R[t_i \mid i \in I]| = \max\{ |A|, |R| \}$ and as we have just seen $|A| = \max\{ |\mathbb{N}|, |I| \}$ this turns into the claim $|R[t_i \mid i \in I]| = \max\{ |\mathbb{N}|, |I|, |R| \}$.

(iii) For any polynomial $f \in R[t]$ let $V_f := \{ x \in S \mid f(x) = 0 \} \subseteq S$. As $S : R$ is algebraic any $s \in S$ is contained in some V_f, that is we have

$$S = \bigcup_{f \in R[t]} V_f$$

And as S is an integral domain any V_f is finite. Also $R[t]$ is infinite, as we have an injection $\mathbb{N} \hookrightarrow R[t] : n \mapsto t^n$. But then we can use (0.38.(vii)) to see, that the cardinality of the union cannot exceed the cardinality of $R[t]$. And by (ii) we know

$$|S| = |\bigcup_{f \in R[t]} V_f| \leq |R[t]| = \max\{ |\mathbb{N}|, |R| \}$$

(iv) The prime field of E either is $P = \mathbb{Z}_p$ for $p = \text{CHAR}(E) \neq 0$ or $P = \mathbb{Q}$ in case $\text{CHAR}(E) = 0$, according to (2.107.(iv)). Thus in both cases P is countable, that is $|P| \leq |\mathbb{N}|$. Now choose a transcendence basis $U \subseteq F$ of $F : P$, that is (1) $F : P[U]$ is algebraic and (2) U is algebraically independent. Because of (2) we get an isomorphism of the following form from (8.46.(i))

$$P[t_u \mid u \in U] \xrightarrow{\sim} P[U] : t_u \mapsto u$$

In particular we get $|P[U]| = |P[t_u \mid u \in U]| = \max\{ |\mathbb{N}|, |P|, |U| \}$, where the latter identity is (ii). But we have already seen $|P| \leq |\mathbb{N}|$ so we can omit $|P|$ in this maximum and $|U|$ is the transcendence degree of $F : U$ by definition. Thus we are left with

$$|P[U]| = \max\{ |\mathbb{N}|, \text{trdeg}(F : P) \}$$

Yet a transcendence basis also satisfies (1) above, that is $F : P[U]$ is algebraic. And in (iii) we have seen that in this case $|F| = |P[U]|$. Combining this with the identity above we arrive at the claim $|F| = \max\{ |\mathbb{N}|, \text{trdeg}(F : P) \}$.

(v) If I is finite, then $R[t_i \mid i \in I]$ is finitely generated and as R is a notherian ring, the Hilbert Basis theorem (2.42) makes $R[t_i \mid i \in I]$ a noetherian ring again and thereby $\mathfrak{a}$ is finitely

generated. That is statement (1) of the claim. For statement (2) the set I is infinite. Let $\Omega(I) := \{\, \omega \subseteq I \mid \#\omega < \infty \,\}$ be the set of finite subsets of I. Then for any $\omega \in \Omega(I)$ the ring

$$R_\omega \;:=\; R[t_i \mid i \in \omega]$$

can be seen as a subring of $R[t_i \mid i \in I]$. By construction R_ω is finitely generated and hence by (1) $\mathfrak{a}_\omega := \mathfrak{a} \cap R_\omega$ is finitely generated. Let $A_\omega \subseteq R_\omega \subseteq R[t_i \mid i \in I]$ be a finite set, such that $\mathfrak{a}_\omega = \langle A_\omega \rangle_{\mathfrak{i}}$ and take

$$A \;:=\; \bigcup_{\omega \in \Omega(I)} A_\omega$$

By (7.23.(i)) any $f \in R[t_i \mid i \in I]$ is contained in some $f \in R_\omega$, for a sufficient $\omega \in \Omega(I)$. In particular any $f \in \mathfrak{a}$ is contained in some $f \in \mathfrak{a}_\omega = \mathfrak{a} \cap R_\omega$ for the same $\omega \in \Omega(I)$. And thereby

$$\mathfrak{a} \;=\; \bigcup_{\omega \in \Omega(I)} \mathfrak{a}_\omega \;\subseteq\; \sum_{\omega \in \Omega(I)} \mathfrak{a}_\omega \;\subseteq\; \mathfrak{a}$$

Generally the union generates the sum, but as the union is an ideal already, that contains any $\mathfrak{a}_\omega$, it also contains their sum and thereby the union and sum are identical. Now, as any $\mathfrak{a}_\omega$ is generated by A_ω, the union A of these sets generates all the ideals $\mathfrak{a}_\omega$ and thereby it generates $\mathfrak{a}$:

$$\langle A \rangle_{\mathfrak{i}} \;=\; \sum_{\omega \in \Omega(I)} \langle A_\omega \rangle_{\mathfrak{i}} \;=\; \sum_{\omega \in \Omega(I)} \mathfrak{a}_\omega \;=\; \mathfrak{a}$$

As I is infinite we have $|\Omega(I)| = |I|$, according to property (d) of (0.38.(v)). And as any A_ω is finite (0.38.(vii)) tells us, that the cardinality of A is bounded by the cardinality of the index set

$$|A| \;\leq\; |\Omega(I)| \;=\; |I|$$

□

Proof of (8.66):

- Let us first prove the implication (a) $\implies$ (b) for saturated CPI of R: Suppose $\mathcal{P} = (\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ is a maximal element of $\mathrm{CPI}^{\mathfrak{q}}_{\mathfrak{p}}(R)$ and consider some prime ideal $\mathfrak{p}$ such that $\mathfrak{p}_{k-1} \subseteq \mathfrak{p} \subseteq \mathfrak{p}_k$. If we had $\mathfrak{p}_{k-1} \neq \mathfrak{p}$ and $\mathfrak{p}_k \neq \mathfrak{p}$, then we could extend $\mathcal{P}$ to $\mathcal{P}' := (\mathfrak{p}_0, \ldots, \mathfrak{p}_{k-1}, \mathfrak{p}, \mathfrak{p}_k, \ldots, \mathfrak{p}_m)$. But then $\mathcal{P} < \mathcal{P}'$ would contradict the maximality of $\mathcal{P}$.

 Conversely suppose $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m) \leq (\mathfrak{q}_0, \ldots, \mathfrak{q}_n)$ for some CPI with $\mathfrak{q}_0 = \mathfrak{p}_0$ and $\mathfrak{q}_n = \mathfrak{p}_m$. If we had $m < n$, then we could take $k \in 1 \ldots n-1$ be the minimal number, such that $\mathfrak{p} := \mathfrak{q}_k$ does not belong to $\{\, \mathfrak{p}_0, \ldots, \mathfrak{p}_m \,\}$. As k is minimal, we still have $\mathfrak{p}_{k-1} = \mathfrak{p}_{k-1} \subset \mathfrak{p}$. By assumption $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m) \leq (\mathfrak{q}_0, \ldots, \mathfrak{q}_n)$ there is some $l \in k+1 \ldots n$ with $\mathfrak{p}_k = \mathfrak{q}_l$. And as $\mathfrak{p} = \mathfrak{q}_k \subset \mathfrak{q}_l = \mathfrak{p}_k$ we also have $\mathfrak{p} \subset \mathfrak{p}_k$. This contradicts (b), such that we have $m = n$ and thereby $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m) = (\mathfrak{q}_0, \ldots, \mathfrak{q}_n)$.

- Let us now prove the implication (a) $\implies$ (b) for maximal CPI of R, that is $\mathcal{P} = (\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ is a maximal element of $\mathrm{CPI}(R)$ and we have to prove the properties (1) to (3) of (b). If $\mathcal{P}$ was not saturated, then there was some CPI $\mathcal{P}'$ with $\mathcal{P} < \mathcal{P}'$ which is ruled out by (a). If $\mathfrak{p}_m$ wasn't maximal, then by (2.4.(ii)) there was some maximal ideal $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} R$ with $\mathfrak{p}_m \subseteq \mathfrak{p}$. But as $\mathfrak{p}_m$ isn't

maximal itself we have $\mathfrak{p}_m \neq \mathfrak{m}$. Also any maximal ideal is prime and hence $\mathcal{P}' := (\mathfrak{p}_0, \ldots, \mathfrak{p}_m, \mathfrak{m})$ would be a CPI of R, extending $\mathcal{P}$, contradicting the maximality of $\mathcal{P}$ again. Analogously, if $\mathfrak{p}_0$ wasn't minimal, then there was a prime ideal $\mathfrak{p} \subset \mathfrak{p}_0$ such that $\mathcal{P}' := (\mathfrak{p}, \mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ would be a CPI of R, extending $\mathcal{P}$. Thus (1) to (3) have to be satisfied.

Conversely suppose $\mathcal{P} = (\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ satisfies (1) to (3) of (b) and consider any $\mathcal{P}' = (\mathfrak{q}_0, \ldots, \mathfrak{q}_n)$ with $\mathcal{P} \leq \mathcal{P}'$. In particular there is some $i \in 0 \ldots n$ such that $\mathfrak{p}_0 = \mathfrak{q}_i$. Suppose we had $i > 0$, then $\mathfrak{q}_0 \subset \mathfrak{q}_i = \mathfrak{p}_0$ such that $\mathfrak{p}_0$ would not be minimal. Therefore we have $i = 0$ and that is $\mathfrak{q}_0 = \mathfrak{p}_0$. Likewise there is some $j \in 0 \ldots n$ with $\mathfrak{p}_m = \mathfrak{q}_j$. Suppose we had $j < n$, then $\mathfrak{p}_m = \mathfrak{q}_j \subset \mathfrak{q}_n \neq R$ which contradicts the maximality of $\mathfrak{p}_m$. Therefore we also have $\mathfrak{p}_m = \mathfrak{q}_n$. That is $\mathcal{P}'$ satisfies the properties required in (a) for the saturated chain $\mathcal{P}$ and therefore we can conclude $\mathcal{P} = \mathcal{P}'$ which is the maximality of $\mathcal{P}$ in $\mathrm{CPI}(R)$.

□

Proof of (8.75):

(i) Let R be holodimensional and $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ be a prime ideal, then we will prove the identity for the Krull-dimension of R in (i) first: As $\mathrm{kdim}(R) < \infty$ we can find a maximal CPI $\mathcal{P} = (\mathfrak{p}_0, \ldots, \mathfrak{p}_n)$ that extends $(\mathfrak{p}) \in \mathrm{CPI}(R)$. From $(\mathfrak{p}) \leq \mathcal{P}$ we find some $k \in 0 \ldots n$ such that $\mathfrak{p}_k = \mathfrak{p}$. But then we conclude:

As $(\mathfrak{p}_0, \ldots, \mathfrak{p}_k)$ is a CPI with $\mathfrak{p}_k = \mathfrak{p}$ we have $\mathrm{height}(\mathfrak{p}) \geq k$. And as $(\mathfrak{p}_k/\mathfrak{p}, \ldots, \mathfrak{p}_n/\mathfrak{p})$ is a CPI in $R/\mathfrak{p}$ we also have $\mathrm{kdim}(R/\mathfrak{p}) \geq n - k$. Together this is

$$\mathrm{kdim}(R) \;=\; n \;=\; (n-k)+k \;\leq\; \mathrm{kdim}\left(R \Big/ \mathfrak{p}\right) + \mathrm{height}(\mathfrak{p}) \;\leq\; \mathrm{kdim}(R)$$

where the latter estimate is (8.69.(x)). Together this implies the equality of the Krull-dimension of R and the Krull-dimension of $R/\mathfrak{p}$ plus the height of $\mathfrak{p}$.

- Let R be a holodimensional ring, then we will now prove that R also is equidimensional: Consider any maximal ideal $\mathfrak{m}$ of R, as R has finite Krull-dimension we have $\mathrm{height}(\mathfrak{m}) \leq \mathrm{kdim}(R) < \infty$. Hence we may pick up a CPI $\mathcal{P} = (\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ of R such that $\mathfrak{p}_m = \mathfrak{m}$ and $m = \mathrm{height}(\mathfrak{m})$. This CPI is maximal - if it could be extended, then the extended chain would be longer. And as $\mathfrak{p}_m = \mathfrak{m}$ is maximal this would increase the height of $\mathfrak{m}$, which is fixed at m.

 Yet as R is holodimensional, this means $\mathrm{height}(\mathfrak{m}) = \ell(\mathcal{P}) = \mathrm{kdim}(R)$. And as this is true for any maximal ideal $\mathfrak{m}$ of R, all maximal ideals of R share the same height, namely $\mathrm{kdim}(R)$.

- Let R be a holodimensional ring, then we will now prove that R also is catenary: Consider any two prime ideals $\mathfrak{p}$, $\mathfrak{q}$ of R such that $\mathfrak{p} \subset \mathfrak{q}$. As $\mathrm{kdim}(R) < \infty$ we can find a maximal CPI $\mathcal{P}$ in R such that $(\mathfrak{p}, \mathfrak{q}) \leq \mathcal{P}$. Say $\mathcal{P} = (\mathfrak{p}_0, \ldots, \mathfrak{p}_n)$ then there are some $0 \leq i < j \leq n$ such that $\mathfrak{p}_i = \mathfrak{p}$ and $\mathfrak{p}_j = \mathfrak{q}$. As $\mathcal{P}$ is maximal, the subchain $\mathcal{P}_0 := (\mathfrak{p}_i, \ldots, \mathfrak{p}_j) \leq \mathcal{P}$ is saturated. In particular property (1) of catenary rings is satisfied.

 And as R is holodimensional we also have $n = \ell(\mathcal{P}) = \mathrm{kdim}(R)$. For property (2) of catenary rings, we have to look at any other saturated CPI $\mathcal{Q} = (\mathfrak{q}_0, \ldots, \mathfrak{q}_m) \in \mathrm{CPI}^{\mathfrak{q}}_{\mathfrak{p}}(R)$. Then by construction

$$(\mathfrak{p}_0, \ldots, \mathfrak{p}_{i-1}, \mathfrak{q}_0, \ldots, \mathfrak{q}_m, \mathfrak{p}_{j+1}, \ldots, \mathfrak{p}_n)$$

also is a maximal CPI of R: As $\mathfrak{p}_i = \mathfrak{p} = \mathfrak{q}_0$ and $\mathfrak{p}_j = \mathfrak{p} = \mathfrak{q}_m$ the CPI $\mathcal{Q}$ can be inserted seamlessly. Still $\mathfrak{p}_0$ is a minimal prime and $\mathfrak{p}_n$ is a maximal ideal and we cannot insert any prime ideal in between, as all the chains $(\mathfrak{p}_0, \ldots, \mathfrak{p}_{i-1})$, $\mathcal{Q}$ and $(\mathfrak{p}_{j+1}, \ldots, \mathfrak{p}_n)$ are saturated. But as this CPI is maximal it is of length $\operatorname{kdim}(R)$ as well. And this implies $\ell(\mathcal{Q}) = \ell(\mathcal{P})$. As we have fixed $\mathcal{P}$ and this is true for any saturated $\mathcal{Q} \in \operatorname{CPI}_{\mathfrak{p}}^{\mathfrak{q}}(R)$, all these CPI must be of the same length.

(iii) Let us now prove (iii): First of all $\operatorname{kdim}(R/\mathfrak{p}) \leq \operatorname{kdim}(R) < \infty$ such that $R/\mathfrak{p}$ has finite Krull-dimension again. So consider any maximal CPI $\mathcal{U} = (\mathfrak{u}_0, \ldots, \mathfrak{u}_m)$ of $R/\mathfrak{p}$. As this is maximal $\mathfrak{u}_0$ is a minimal prime of $R/\mathfrak{p}$, but as $\mathfrak{p}$ is a prime ideal $R/\mathfrak{p}$ is an integral domain, so the one and only minimal prime of $R/\mathfrak{p}$ is the zero ideal $\mathfrak{u}_0 = 0$.

By the correspondence theorem of ideals, any $\mathfrak{u}_i$ is of the form $\mathfrak{u}_i = \mathfrak{q}_i/\mathfrak{p}$ for some $\mathfrak{q}_i \in \operatorname{Spec}(R)$ with $\mathfrak{p} \subseteq \mathfrak{q}_i$. That is we find a CPI $\mathcal{Q} = (\mathfrak{q}_0, \ldots, \mathfrak{q}_m)$ of R. And as $\mathfrak{q}_0/\mathfrak{p} = \mathfrak{u}_0 = 0$ we have $\mathfrak{q}_0 = \mathfrak{p}$. Now pick up a CPI $\mathcal{P} = (\mathfrak{p}_0, \ldots, \mathfrak{p}_k)$ of R such that $\mathfrak{p}_k = \mathfrak{p}$ and $k = \operatorname{height}(\mathfrak{p})$. As we have $\mathfrak{p}_k = \mathfrak{p} = \mathfrak{q}_0$ we can concatenate these CPI to a single chain

$$\mathcal{M} := (\mathfrak{p}_0, \ldots, \mathfrak{p}_k = \mathfrak{q}_0, \mathfrak{q}_1, \ldots, \mathfrak{q}_m)$$

Both $\mathcal{P}$ and $\mathcal{U}$ are maximal and hence saturated. This means $\mathcal{Q}$ is saturated again (by the correspondence of ideals). Also $\mathfrak{q}_m$ is a maximal ideal, as $\mathfrak{u}_m$ is, too. Altogether $\mathcal{M}$ is a maximal CPI of R and thereby, as R is holodimensional

$$\operatorname{kdim}(R) \;=\; \ell(\mathcal{M}) \;=\; k+m \;=\; \operatorname{height}(\mathfrak{p}) + \ell(\mathcal{U})$$

Therefore $\ell(\mathcal{U}) = \operatorname{kdim}(R) - \operatorname{height}(\mathfrak{p})$ is independent of the specific ideals that build up the maximal chain $\mathcal{U}$. As there is some CPI $\mathcal{V} \in \operatorname{CPI}(R/\mathfrak{p})$ with $\ell(\mathcal{V}) = \operatorname{kdim}(R/\mathfrak{p})$ and any such CPI is maximal we conclude $\ell(\mathcal{U}) = \ell(\mathcal{V}) = \operatorname{kdim}(R/\mathfrak{p})$ for any maximal CPI $\mathcal{U}$ of $R/\mathfrak{p}$. And this means $R/\mathfrak{p}$ is holodimensional, too.

(iv) We start with (a) $\Longrightarrow$ (b): As $\mathfrak{q} \trianglelefteq_{\mathrm{i}} R$ is of finite height, so is $\mathfrak{q}/\mathfrak{p} \trianglelefteq_{\mathrm{i}} R/\mathfrak{p}$, by the correspondence theorem of ideals (8.65.(i)). So let us take any CPI $\mathfrak{q}_0/\mathfrak{p} \subset \ldots \subset \mathfrak{q}_s/\mathfrak{p}$ with $\mathfrak{q}_s/\mathfrak{p} = \mathfrak{q}/\mathfrak{p}$ and $s = \operatorname{height}(\mathfrak{q}/\mathfrak{p})$. Note that this is $\mathfrak{q}_s = \mathfrak{q}$. Also $\mathfrak{p}_0/\mathfrak{p} = 0$: As $R/\mathfrak{p}$ is an integral domain 0 is a prime ideal and hence we could append $0 \subset \mathfrak{q}_0/\mathfrak{p} \subset \ldots \subset \mathfrak{q}_s/\mathfrak{p}$, which would be a CPI of length $s+1$, exceeding s. And this means $\mathfrak{q}_0 = \mathfrak{p}$, as well. Now suppose there was some $\mathfrak{q}' \in \operatorname{Spec}(R)$ such that $\mathfrak{q}_{k-1} \subset \mathfrak{q}' \subset \mathfrak{q}_k$ then we also had $\mathfrak{q}_{k-1}/\mathfrak{p} \subset \mathfrak{q}'/\mathfrak{p} \subset \mathfrak{q}_k/\mathfrak{p}$ such that we could find a CPI of length $s+1$ ending in $\mathfrak{q}/\mathfrak{p}$. As s is maximal with this property this means $\mathfrak{q}_{k-1} \subset_* \mathfrak{q}_k$ such that by assumption (a) we have $\operatorname{height}(\mathfrak{q}_k) = \operatorname{height}(\mathfrak{q}_{k-1}) + 1$. And from this we get

$$\operatorname{height}(\mathfrak{q}) - \operatorname{height}(\mathfrak{p}) \;=\; \sum_{k=1}^{s} \big(\operatorname{height}(\mathfrak{q}_k) - \operatorname{height}(\mathfrak{q}_{k-1})\big) \;=\; s \;=\; \operatorname{height}\left(\mathfrak{q} \Big/ \mathfrak{p}\right)$$

Conversely for (b) $\Longrightarrow$ (a): If $\mathfrak{p} \subset_* \mathfrak{q}$ then $(\mathfrak{p}, \mathfrak{q})$ is a CPI in R. Consider any CPI in $R/\mathfrak{p}$ such that $0 = \mathfrak{p}_0/\mathfrak{p} \subset \ldots \subset \mathfrak{p}_r/\mathfrak{p}$ such that $\mathfrak{p}_0 = \mathfrak{p}$ and $\mathfrak{p}_r = \mathfrak{q}$. Then we have $\mathfrak{p} = \mathfrak{p}_0 \subset \mathfrak{p}_1 \subseteq \mathfrak{p}_r = \mathfrak{q}$, by the correspondence theorem of ideals. But as $\mathfrak{q}$ is minimal over $\mathfrak{p}$ and $\mathfrak{p} \subset \mathfrak{p}_1$ this is $\mathfrak{p}_1 = \mathfrak{q}$, in other words $r = 1$. Therefore we have $\operatorname{height}(\mathfrak{q}/\mathfrak{p}) = 1$ and due to (b) this yields $\operatorname{height}(\mathfrak{q}) - \operatorname{height}(\mathfrak{p}) = 1$. But this already is (a).

It remains to prove that (a) and (b) imply R to be catenary. So fix any two nested primes $\mathfrak{p} \subseteq \mathfrak{q}$ of R. As $n := \text{height}(\mathfrak{q}) < \infty$ is finite the following set is bounded by n from above

$$\left\{ s \in \mathbb{N} \;\middle|\; (\mathfrak{q}_0, \ldots, \mathfrak{q}_s) \in \text{CPI}_{\mathfrak{p}}^{\mathfrak{q}} \right\}$$

In particular we can fix any CPI $\mathfrak{p} = \mathfrak{q}_0 \subset \ldots \subset \mathfrak{q}_s = \mathfrak{q}$ of maximal length s. And by the maximality of s, this CPI is saturated - if we could insert some $\mathfrak{p}' \in \text{Spec}(R)$ in between any $\mathfrak{q}_{k-1} \subset \mathfrak{q}_k$ we would get a CPI longer than s. Thus $\mathfrak{p}$ and $\mathfrak{q}$ can be connected by a saturated CPI.

Now consider any saturated CPI $\mathfrak{p} = \mathfrak{p}_0 \subset \ldots \subset \mathfrak{p}_r = \mathfrak{q}$. Being saturated means $\mathfrak{p}_{k-1} \subset_* \mathfrak{p}_k$ for any $k \in 1 \ldots r$. But by (a) this means $\text{height}(\mathfrak{p}_k) = \text{height}(\mathfrak{p}_{k-1}) + 1$. But as in (a) $\implies$ (b) before we hence get

$$r \;=\; \sum_{k=1}^{r} \big(\text{height}(\mathfrak{p}_k) - \text{height}(\mathfrak{p}_{k-1}) \big) \;=\; \text{height}(\mathfrak{q}) - \text{height}(\mathfrak{p})$$

That is the length of all saturated CPIs from $\mathfrak{p}$ to $\mathfrak{q}$ is fixed to be $\text{height}(\mathfrak{q}) - \text{height}(\mathfrak{p})$, which is invariant under the respective CPI chosen. And thereby R is catenary.

(v) The proof of (v) follows the same lines as the proof of (iii): First of all by (8.69.(ix)) we have $\text{kdim}(R_{\mathfrak{p}}) = \text{height}(\mathfrak{p}) \leq \text{kdim}(R) < \infty$ again. So consider any maximal CPI $\mathcal{U} = (\mathfrak{u}_0, \ldots, \mathfrak{u}_m)$ of $R_{\mathfrak{p}}$. As this is maximal $\mathfrak{u}_m$ is a maximal ideal, so we have $\mathfrak{u}_m = \mathfrak{p}R_{\mathfrak{p}}$, as this is the only maximal ideal available in $R_{\mathfrak{p}}$.

Now, by the correspondence theorem of ideals in localisations, any $\mathfrak{u}_i$ is if the form $\mathfrak{u}_i = \mathfrak{p}_i R_{\mathfrak{p}}$ for some prime ideal $\mathfrak{p}_i \trianglelefteq_{\mathfrak{i}} R$ with $\mathfrak{p}_i \subseteq \mathfrak{p} = \mathfrak{p}_m$, also refer to (8.65.(ii)) for this. Hence we have found a CPI $\mathcal{P} = (\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ of R of length m, with $\mathfrak{p}_m = \mathfrak{p}$.

Now pick up a CPI $\mathcal{V} = (\mathfrak{v}_0, \ldots, \mathfrak{v}_n)$ of $R/\mathfrak{p}$ such that $n = \text{kdim}(R/\mathfrak{p})$. As in the proof of (ii) above any $\mathfrak{v}_j$ is of the form $\mathfrak{v}_j = \mathfrak{q}_j/\mathfrak{p}$ for some prime ideal $\mathfrak{q}_j \trianglelefteq_{\mathfrak{i}} R$ and $\mathfrak{p}_0 = \mathfrak{p}$ as $\mathfrak{v}_0 = 0$. And as before $\mathcal{Q} = (\mathfrak{q}_0, \ldots, \mathfrak{q}_n)$ is a CPI of R of length n. As we have $\mathfrak{p}_m = \mathfrak{p} = \mathfrak{q}_0$ we can concatenate these CPI to a single chain, once again

$$\mathcal{M} \;:=\; (\mathfrak{p}_0, \ldots, \mathfrak{p}_m = \mathfrak{q}_0, \mathfrak{q}_1, \ldots, \mathfrak{q}_n)$$

Both $\mathcal{U}$ and $\mathcal{V}$ are maximal and hence saturated. This means both $\mathcal{P}$ and $\mathcal{Q}$ are saturated again (by the correspondence of ideals). Also $\mathfrak{q}_n$ is a maximal ideal, as $\mathfrak{v}_n$ is, too. And $\mathfrak{p}_0$ is a minimal prime, as $\mathcal{U}$ is maximal and hence $\mathfrak{u}_0$ is a minimal prime, too. Altogether $\mathcal{M}$ is a maximal CPI of R and thereby, as R is holodimensional

$$\text{kdim}(R) \;=\; \ell(\mathcal{M}) \;=\; m + n \;=\; \ell(\mathcal{U}) + \text{kdim}\left(R \Big/ \mathfrak{p} \right)$$

Therefore $\ell(\mathcal{U}) = \text{kdim}(R) - \text{kdim}(R/\mathfrak{p})$ is independent of the specific ideals that build up the maximal chain $\mathcal{U}$. As there is some CPI $\mathcal{V} \in \text{CPI}(R_{\mathfrak{p}})$ with $\ell(\mathcal{V}) = \text{kdim}(R_{\mathfrak{p}})$ and any such CPI is maximal we conclude $\ell(\mathcal{U}) = \ell(\mathcal{V}) = \text{kdim}(R_{\mathfrak{p}})$ for any maximal CPI $\mathcal{U}$ of $R_{\mathfrak{p}}$. And this means $R_{\mathfrak{p}}$ is holodimensional, too.

(ii) We are now ready to prove (ii): Consider a saturated CPI $\mathfrak{p}_0 \subset \ldots \subset \mathfrak{p}_r$ such that $\mathfrak{p}_0 = \mathfrak{p}$ and

$\mathfrak{p}_r = \mathfrak{q}$. By the correspondence theorem (8.65.(i)) we get a saturated CPI in $R/\mathfrak{p}$ by going to quotients $0 = \mathfrak{p}_0/\mathfrak{p} \subset \ldots \subset \mathfrak{p}_r/\mathfrak{p}$. As $R/\mathfrak{p}$ is holodimensional (in particular $\operatorname{kdim}(R/\mathfrak{p}) < \infty$) by assumption, we can append this to a maximal CPI of $R/\mathfrak{p}$

$$0 \;=\; \mathfrak{p}_0\Big/_{\mathfrak{p}} \;\subset\; \mathfrak{p}_0\Big/_{\mathfrak{p}} \;\subset\; \mathfrak{p}_s\Big/_{\mathfrak{p}}$$

where $s = \operatorname{kdim}(R/\mathfrak{p})$. As this chain is maximal $\mathfrak{p}_s \trianglelefteq_{\mathrm{i}} R$ is a maximal ideal. For any $k \in r \ldots s$ we have $\mathfrak{q} = \mathfrak{p}_r \subseteq \mathfrak{p}_k$ such that by (8.65.(i)) we obtain another CPI, in $R/\mathfrak{q}$ this time

$$0 \;=\; \mathfrak{p}_r\Big/_{\mathfrak{q}} \;\subset\; \ldots \;\subset\; \mathfrak{p}_s\Big/_{\mathfrak{q}}$$

This CPI is saturated, by correspondence, and as $\mathfrak{p}_s/\mathfrak{q}$ is a maximal ideal of $R/\mathfrak{q}$ and $\mathfrak{p}_r/\mathfrak{q} = 0$ this chain is maximal, too. As $R/\mathfrak{q}$ is holodimensional, this again means $\operatorname{kdim}(R/\mathfrak{q}) = s - r$, as this is the length of this chain. Thus we can express the length r of the chain in the beginning in terms

$$\operatorname{kdim}\left(R\Big/_{\mathfrak{p}}\right) - \operatorname{kdim}\left(R\Big/_{\mathfrak{q}}\right) \;=\; s - (s-r) \;=\; r$$

And if we use the dimension formula of (i) for $R/\mathfrak{p}$ and $R/\mathfrak{q}$, which are both holodimensional, we can also express this in terms of the height of these ideals

$$\begin{aligned}\operatorname{height}(\mathfrak{q}) - \operatorname{height}(\mathfrak{p}) &= \operatorname{kdim}(R) - \operatorname{kdim}\left(R\Big/_{\mathfrak{q}}\right) - \operatorname{kdim}(R) + \operatorname{kdim}\left(R\Big/_{\mathfrak{p}}\right)\\ &= \operatorname{kdim}\left(R\Big/_{\mathfrak{p}}\right) - \operatorname{kdim}\left(R\Big/_{\mathfrak{p}}\right) \;=\; r\end{aligned}$$

- By the above we know, that $\ell(\mathcal{P}) = \operatorname{height}(\mathfrak{q}) - \operatorname{height}(\mathfrak{p})$ for any saturated CPI $\mathcal{P}$ ranging from $\mathfrak{p}$ to $\mathfrak{q}$. To prove the final equality $\operatorname{height}(\mathfrak{q}/\mathfrak{p}) = \operatorname{height}(\mathfrak{q}) - \operatorname{height}(\mathfrak{p})$ we start with a CPI in $R/\mathfrak{p}$ that is of the form

$$\mathfrak{p}_0\Big/_{\mathfrak{p}} \;\subset\; \ldots \;\subset\; \mathfrak{p}_r\Big/_{\mathfrak{p}} \;=\; \mathfrak{q}\Big/_{\mathfrak{p}}$$

where $r = \operatorname{height}(\mathfrak{q}/\mathfrak{p})$. As r is maximal and $R/\mathfrak{p}$ is an integral domain, we have $\mathfrak{p}_0/\mathfrak{p} = 0$, which is $\mathfrak{p}_0 = \mathfrak{p}$. Also $\mathcal{P} = (\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$ is saturated: If we could insert some $\mathfrak{p}' \in \operatorname{Spec}(R)$ at any position $\mathfrak{p}_{i-1} \subset \mathfrak{p}' \subset \mathfrak{p}_i$ then $\mathfrak{p}_{i-1}/\mathfrak{p} \subset \mathfrak{p}'/\mathfrak{p} \subset \mathfrak{p}_i/\mathfrak{p}$ which would yield a longer chain, that does not exist. Now, as $\mathcal{P}$ is a saturated chain ranging from $\mathfrak{p}$ to $\mathfrak{q}$, we get

$$\operatorname{height}(\mathfrak{q}) - \operatorname{height}(\mathfrak{p}) \;=\; \ell(\mathcal{P}) \;=\; r \;=\; \operatorname{height}\left(\mathfrak{q}\Big/_{\mathfrak{p}}\right)$$

(vi) As R is equidimensional, we have $\operatorname{kdim}(R) < \infty$ and hence we can choose some CPI $\mathcal{Q} = (\mathfrak{q}_0, \ldots, \mathfrak{q}_n)$ of R with $n = \operatorname{kdim}(R)$. Thereby $\mathcal{Q}$ is maximal and hence $\mathfrak{n} := \mathfrak{q}_n$ is a maximal ideal. In particular $\operatorname{height}(\mathfrak{n}) = n$, as

$$n \;\leq\; \operatorname{height}(\mathfrak{n}) \;\leq\; \operatorname{kdim}(R) \;=\; n$$

Now consider any maximal CPI $\mathcal{P} = (\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ of R. We have to show $\ell(\mathcal{P}) = \operatorname{kdim}(R)$, that is $m = n$. As $\mathcal{P}$ is maximal $\mathfrak{p}_0$ is a minimal prime and $\mathfrak{m} := \mathfrak{p}_m$ is a maximal ideal. Also $\mathcal{P}$ is saturated. Yet R is an integral domain, so the only minimal prime ideal available is $\mathfrak{p}_0 = 0$.

Now pick up a CPI $\mathcal{H} = (\mathfrak{h}_0, \ldots, \mathfrak{h}_r)$ of R such that $\mathfrak{h}_r = \mathfrak{m}$ and $r = \operatorname{height}(\mathfrak{m})$. Again, as $\mathcal{H}$ is a

chain that builds up the height of $\mathfrak{m}$ it must be saturated and $\mathfrak{h}_0 = 0$, as R is an integral domain. That is we have found two CPI $\mathcal{H}$ and $\mathcal{P} \in \mathrm{CPI}_0^{\mathfrak{m}}(R)$ that both are saturated and hence we have $r = \ell(\mathcal{H}) = \ell(\mathcal{P}) = m$ by property (2) of catenary rings. Yet $\mathfrak{m}$ is a maximal ideal and R also is equidimensional, such that $r = \mathrm{height}(\mathfrak{m}) = \mathrm{height}(\mathfrak{n}) = n$. Altogether we have found

$$\ell(\mathcal{P}) \;=\; m \;=\; r \;=\; n \;=\; \mathrm{kdim}(R)$$

□

Proof of (8.76):

(i) Let $\mathfrak{q}_0 \subset \mathfrak{q}_1 \subset \ldots \subset \mathfrak{q}_r$ be a maximal CPI in A. By the Noetherian normalisation theorem (8.52) there are some $z_1, \ldots, z_n \in A$ and $0 \leq k(0) \leq k(1) \leq \cdots \leq k(r) \leq n$ such that $\{ z_1, \ldots, z_n \}$ is algebraically independent, $A : P$ is finite and for any $i \in 0 \ldots r$ we get

$$\mathfrak{q}_i \cap P \;=\; z_1 P + \cdots + z_{k(i)} P$$

where $P = E[z_1, \ldots, z_n] \subseteq A$ and $n = \mathrm{trdeg}(A : E)$. As the chain is maximal and A is an integral domain, we have $\mathfrak{q}_0 = 0$ and hence $k(0) = 0$. Also, as the $\mathfrak{q}_i$ form a CPI and $A : P$ is integral (even finite) so do the restricted ideals $\mathfrak{p}_i := \mathfrak{q}_i \cap P$, according to the lying-over theorem (8.32.(iii))

$$0 = \mathfrak{p}_0 \subset \mathfrak{p}_1 \subset \ldots \subset \mathfrak{p}_r$$

As $\mathfrak{p}_i = \mathfrak{q}_i \cap P = z_1 P + \cdots + z_{k(i)} P$ we see that $0 = k(0) < k(1) < \cdots < k(r)$ as well, as $k(i-1) = k(i)$ would imply $\mathfrak{p}_{i-1} = \mathfrak{p}_i$ and hence $\mathfrak{q}_{i-1} = \mathfrak{q}_i$. In particular we conclude $r \leq n$.

- Now fix any $i \in 1 \ldots r$ and let $k := k(i-1)$, $m := n - k$. We also abbreviate $Q_i := A/\mathfrak{q}_{i-1}$ and $u_j := z_{j+k} + \mathfrak{q}_{i-1} \in Q_i$ for any $j \in 1 \ldots m$. With these notations let us prove, that

$$E[u_1, \ldots, u_m] \;=\; \{ p + \mathfrak{q}_{i-1} \mid p \in P \}$$

For any $q \in E[u_1, \ldots, u_m]$ there is some polynomial $f \in E[t_1, \ldots, t_m]$ such that $q = f(u_1, \ldots, u_m) = f(z_{i+k}, \ldots, z_n) + \mathfrak{q}_{i-1}$. As $P = E[z_1, \ldots, z_n]$ it is clear, that $p := f(z_{i+k}, \ldots, z_n) \in P$ and thereby $q = p + \mathfrak{q}_{i-1}$ is contained in the right-hand set. Conversely we start with some $p \in P$, that is $p = f(z_1, \ldots, z_n)$ for some polynomial $f \in E[t_1, \ldots, t_n]$. Note that for any $j \in 1 \ldots k$ we have $z_j \in z_j P \subseteq \mathfrak{q}_{i-1} \cap P \subseteq \mathfrak{q}_{i-1}$. That is $z_j + \mathfrak{q}_{i-1} = 0 + \mathfrak{q}_{i-1}$. And for $j \in k+1 \ldots n$ we have $z_j + \mathfrak{q}_{i-1} = u_{j-k}$ by construction. Thus we find

$$p + \mathfrak{q}_{i-1} \;=\; f\big(z_1 + \mathfrak{q}_{i-1}, \ldots, z_n + \mathfrak{q}_{i-1}\big) \;=\; f(0, \ldots, 0, u_1, \ldots, u_m)$$

That is $p + \mathfrak{q}_{i-1} = f(0, \ldots, 0, u_1, \ldots, u_m) \in E[u_1, \ldots, u_m]$. This establishes the inclusion from right to left and thereby the equality of these sets.

- In the next step we prove, that $\{ u_1, \ldots, u_m \} \subseteq Q_i$ is algebraically independent. To do this consider any polynomial $f \in E[t_1, \ldots, t_m]$ such that

$$0 + \mathfrak{q}_{i-1} \;=\; f(u_1, \ldots, u_m) \;=\; f(z_{k+1}, \ldots, z_n) + \mathfrak{q}_{i-1}$$

That is $p := f(z_{k+1},\dots,z_n) \in \mathfrak{q}_{i-1}$. But as $p \in P$ is clear, as well, we find, that p is contained, in $p \in \mathfrak{q}_{i-1} \cap P = z_1P + \cdots + z_kP \subseteq E[z_1,\dots,z_k]$. From the construction of p it is also clear, that $p \in E[z_{k+1},\dots,z_n]$ and therefore

$$p \;\in\; E[z_1,\dots,z_k] \cap E[z_{k+1},\dots,z_n] \;=\; E$$

As the sets of variables are mutually exclusive [recall that $\{ z_1,\dots,z_n \}$ is algebraically independent] the only polynomials that are contained in both sets are constant $p \in E$. But we have $p \in \mathfrak{q}_{i-1}$ and $\mathfrak{q}_{i-1} \neq A$, as it was a prime ideal. This only leaves $p = 0$ and as $\{ z_{k+1},\dots,z_n \}$ is algebraically independent, this means $f = 0$. That is $\{ u_1,\dots,u_m \}$ is algebraically independent, too.

- Denote the canonical epimorphism by $\varrho : A \twoheadrightarrow Q_i : x \mapsto x + \mathfrak{q}_{i-1}$. Two steps before we have shown $\varrho(P) = E[u_1,\dots,u_m]$. But $A : P$ is integral (even finite), as we gained it by noetherian normalisation. Now, as ϱ is surjective, (8.28) tells us, that $Q_i : E[u_1,\dots,u_m]$ is integral, too.

- Let us abbreviate $P_i := E[u_1,\dots,u_m] \subseteq Q_i$. As the $\{ u_1,\dots,u_m \}$ are algebraically independent, P_i is isomorphic to a polynomial ring in m variables such that the ideals $\mathfrak{u}_j := u_1P_i + \cdots + u_jP_i$ are prime and form a CPI in P_i, too

$$0 \;\subset\; \mathfrak{u}_1 \;\subset\; \dots \;\subset\; \mathfrak{u}_m$$

By construction $\varrho : P \twoheadrightarrow P_i : p \mapsto p + \mathfrak{q}_{i-1}$ is an epimorphism of algebras, as $z_j \in P = E[z_1,\dots,z_n]$ is mapped to $\varrho(z_j) = 0$ for $j \in 1\dots k$ and $\varrho(z_j) = u_{j-k} \in E[u_1,\dots,u_m] = P_i$ for $j \in k+1\dots n$. That is the kernel of this ϱ is given to be $z_1P \dots z_kP = \mathfrak{q}_{i-1} \cap P$ and thereby

$$P \Big/ \mathfrak{q}_{i-1} \cap P \;\xrightarrow{\sim}\; P_i \;:\; z_j \mapsto u_{j-k}$$

Let us denote $l := k(i) - k = k(i) - k(i-1) \in 1\dots m$, then the ideal $\mathfrak{q}_i \cap P = z_1P + \cdots + z_{k(i)}P$ is mapped to $\mathfrak{u}_l = u_1P_i + \cdots + u_lP_i$ under ϱ. We now claim the identity

$$\mathfrak{q}_i \Big/ \mathfrak{q}_{i-1} \cap P_i \;=\; u_1P_i + \cdots + u_lP_i \;=\; \mathfrak{u}_l$$

Let us agree to denote this ideal by $\mathfrak{v}_l := \mathfrak{q}_i/\mathfrak{q}_{i-1}$. The inclusion from right to left is easy as we already know $\mathfrak{u}_l = \varrho(\mathfrak{q}_i \cap P) \subseteq \varrho(\mathfrak{q}_i) = \mathfrak{q}_i/\mathfrak{q}_{i-1} = \mathfrak{v}_l$. For the converse inclusion we consider any $v = q + \mathfrak{q}_{i-1} \in \mathfrak{v}_l \cap P_i$. That is $q \in \mathfrak{q}_i$ and $v \in E[u_1,\dots,u_m]$. That is $v = f(u_1,\dots,u_m)$ for some polynomial f in m variables. Let us write this out

$$v \;=\; f(u_1,\dots,u_m) \;=\; \sum_{\alpha\in\mathbb{N}^l} \sum_{\beta\in\mathbb{N}^{m-l}} f[\alpha,\beta]\,(u_1,\dots,u_l)^\alpha (u_{l+1},\dots,u_m)^\beta$$

and let us abbreviate $f_\alpha := \sum_\beta f[\alpha,\beta]\,(u_{l+1},\dots,u_m)^\beta$ that is $v = \sum_\alpha f_\alpha\,(u_1,\dots,u_l)^\alpha$. Then we split v up into a part $\alpha = 0$ and the rest $\alpha \neq 0$. That is we write v as

$$v \;=\; f_0 + \sum_{\alpha\neq 0} f_\alpha\,(u_1,\dots,u_l)^\alpha$$

If $\alpha \neq 0$ there is some $j \in 1\dots l$ with $\alpha_j \geq 1$ and therefore u^α contains u_j as a factor. Hence all the

$f_\alpha\,(u_1,\ldots,u_l)^\alpha$ are contained in $u_1P_i+\cdots+u_lP_i$ and we have already argued, that this in turn is contained in $\mathfrak{v}_l$. Thus we have $f_\alpha\,(u_1,\ldots,u_l)^\alpha\in\mathfrak{v}_l$ for any $\alpha\neq 0$ and therefore

$$\sum_{\beta\in\mathbb{N}^{m-l}} f[0,\beta]\,(u_{l+1},\ldots,u_m)^\beta \;=\; f_0 \;=\; v-\sum_{\alpha\neq 0} f_\alpha\,(u_1,\ldots,u_l)^\alpha \;\in\; \mathfrak{v}_l \;=\; \mathfrak{q}_i\Big/\mathfrak{q}_{i-1}$$

But as $f_0\in P_i$ there is a uniquely determined $g+\mathfrak{q}_{i-1}\cap P$ such that $\varrho(g)=f_0$, by the above isomorphism. This g obviously is

$$g \;:=\; \sum_{\beta\in\mathbb{N}^{m-l}} f[0,\beta]\,(z_{k(i)+1},\ldots,z_n)^\beta$$

If $g\neq 0$ then $g\notin z_1P+\cdots+z_{k(i)}P=\mathfrak{q}_i\cap P$ is clear. But as $g\in P$ is a given, we can conclude $g=0$ or $g\notin\mathfrak{q}_i$. But as $\mathfrak{q}_{i-1}\cap P\subseteq\mathfrak{q}_{i-1}$ we have $g+\mathfrak{q}_{i-1}=f_0\in\mathfrak{q}_i/\mathfrak{q}_{i-1}$ that is $g+\mathfrak{q}_{i-1}=q+\mathfrak{q}_{i-1}$ for some $q\in\mathfrak{q}_i$. As $\mathfrak{q}_{i-1}\subseteq\mathfrak{q}_i$ we could diffuse further and only regard $g+\mathfrak{q}_i=q+\mathfrak{q}_i=0+\mathfrak{q}_i$ such that $g\in\mathfrak{q}_i$ as well. This only leaves $g=0$ and hence $f_0=0$ such that

$$v \;=\; f(u_1,\ldots,u_m) \;=\; \sum_{\alpha\neq 0} f_\alpha\,(u_1,\ldots,u_l)^\alpha \;\in\; \mathfrak{u}_l$$

- Let us summarize: We have found a CPI $(0,\mathfrak{u}_1,\ldots,\mathfrak{u}_m)$ in $P_i=E[u_1,\ldots,u_m]$ and a prime ideal $\mathfrak{v}_l\trianglelefteq_{\mathfrak{i}} Q_i=A/\mathfrak{q}_{i-1}$ such that $\mathfrak{v}_l\cap P_i=\mathfrak{u}_l$. As P_i is isomorphic to a polynomial ring in m variables, it is a UFD and hence a normal domain. And as $A\neq 0$ (it is an integral domain) and E is a field, A is E-torsion-free. $Q_i\subseteq A$ inherits this property. Finally $Q_i:P_i$ is an integral extension such that we can use the going-down theorem (8.72.(iii)) to find a CPI in Q_i of the form $(\mathfrak{v}_0,\ldots,\mathfrak{v}_l)$, such that $\mathfrak{v}_j\cap P_i=\mathfrak{u}_j$ for any $j\in 0\ldots l$. By the correspondence theorem any $\mathfrak{v}_j\trianglelefteq_{\mathfrak{i}} A/\mathfrak{q}_{i-1}$ is of the form $\mathfrak{v}_j=\mathfrak{r}_j/\mathfrak{q}_{i-1}$ for some prime ideal $\mathfrak{r}_j\in A$ with $\mathfrak{q}_{i-1}\subseteq\mathfrak{r}_j$. That is we have

$$\mathfrak{q}_{i-1}\;\subseteq\;\mathfrak{r}_0\;\subset\;\mathfrak{r}_1\;\subset\;\ldots\;\subset\;\mathfrak{r}_l=\mathfrak{q}_i$$

 Hereby $\mathfrak{r}_l=\mathfrak{q}_i$ is due to the fact, that they correspond to the same ideal $\mathfrak{v}_l$ in Q_i, that is $\mathfrak{r}_l/\mathfrak{q}_{i-1}=\mathfrak{v}_l=\mathfrak{q}_l/\mathfrak{q}_{i-1}$. But the chain $(\mathfrak{q}_0,\ldots,\mathfrak{q}_r)$ was maximal, there are no prime ideals in between $\mathfrak{q}_{i-1}$ and $\mathfrak{q}_i$. That is this chain has to be $\mathfrak{q}_{i-1}=\mathfrak{r}_0\subset\mathfrak{r}_1=\mathfrak{q}_i$ and in particular $1=l=k(i)-k(i-1)$. That is $k(0)=0$ and $k(i)=k(i-1)+1$ for any $i\in 1\ldots r$. This makes $k(i)=i$ for any $i\in 1\ldots r$.

- The assumption that $(\mathfrak{q}_0,\ldots,\mathfrak{q}_r)$ is maximal also makes $\mathfrak{q}_r$ a maximal ideal. Hence $\mathfrak{q}_r\cap P$ is a maximal ideal, too, according to (8.32.(ii)). As $P=E[z_1,\ldots,z_n]$ is isomorphic to a polynomial ring in n variables, the only maximal ideal among the $z_1P+\cdots+z_kP$ is those with $k=n$. That is we have $k(r)=n$ and as we have argued above, this is $r=k(r)=n$. Thus any maximal CPI in A has length $r=n=\operatorname{trdeg}(A:E)$.

(ii) E is a field and hence noetherian. As A is finiely generated, by assumption, we recall the Hilbert basis theorem (2.42) to find that A is a noetherian ring. And any such only has finitely many prime ideals, according to (2.45.(iv)). Now use the Noetherian normalisation theorem [without a chain of ideals] (8.52) to find an an algebraically independent set $\{z_1,\ldots,z_n\}\subseteq A$ and let $P:=E[z_1,\ldots,z_n]$. As the z_i are algebraically independent, P is isomorphic to a polynomial ring $E[t_1,\ldots,t_n]$ in n variables. Thus by (8.77.(i)) we have $\operatorname{kdim}(P)=n$. But as $A:P$ is finite, it also

is integral and thereby we find by (8.73.(i))

$$\mathrm{kdim}(A) \;=\; \mathrm{kdim}(P) \;=\; n \;<\; \infty$$

As A is finite-dimensional, we may choose a CPI $(\mathfrak{q}_0,\ldots,\mathfrak{q}_n)$ of length n in A. Then the chain of quotient ideals $(\mathfrak{q}_0/\mathfrak{q}_0,\ldots,\mathfrak{q}_n/\mathfrak{q}_0)$ is a CPI in $A/\mathfrak{q}_0$ of length n again. In particular the Krull-dimension of $A/\mathfrak{q}_0$ can not be lower than n. Now use (8.69.(x)) to find the following chain of inequalities

$$n \;\leq\; \mathrm{kdim}\left(A\Big/\mathfrak{q}_0\right) \;\leq\; \mathrm{kdim}\left(A\Big/\mathfrak{q}_0\right) + \mathrm{height}(\mathfrak{q}_0) \;\leq\; \mathrm{kdim}(A) \;=\; n$$

Then we have $\mathrm{kdim}(A/\mathfrak{q}_0) = n = \mathrm{kdim}(A)$ and $\mathrm{height}(\mathfrak{q}_0) = 0$. The latter means that $\mathfrak{q}_0$ is a minimal prime ideal of A, due to (8.69.(iii)) and hence we have

$$\mathrm{kdim}(A) \;\leq\; \max\left\{\, \mathrm{kdim}\left(A\Big/\mathfrak{n}\right) \;\Big|\; \mathfrak{n} \in \mathrm{Smin}(A) \,\right\}$$

But for any prime ideal $\mathfrak{q} \trianglelefteq_{\mathrm{i}} A$ we have $\mathrm{kdim}(A/\mathfrak{q}) \leq \mathrm{kdim}(A)$ by the same reasoning - (8.69.(x)) and $\mathrm{height}(\mathfrak{q}) \geq 0$. Thus the converse inequality is a given and hence we have equality.

(iii) $A/\mathfrak{p}$ is an algebra over $E/(\mathfrak{p}\cap E)$ canonically. But as E is a field and $\mathfrak{p}\cap E \trianglelefteq_{\mathrm{i}} E$ is a proper ideal, this means $\mathfrak{p}\cap E = 0$ and hence $E/(\mathfrak{p}\cap E) = E$ canonically. Thus $A/\mathfrak{p}$ is an E-algebra, too. Also, as A is finitely generated, say $A = E[x_1,\ldots,x_n]$, so is $A/\mathfrak{p} = E[x_1+\mathfrak{p},\ldots,x_n+\mathfrak{p}]$. Thus $A/\mathfrak{p}$ is a finitely generated E-algebra and integral domain, as $\mathfrak{p}$ is prime.

Thus by (i) $A/\mathfrak{p}$ is holodimensional of dimension $\mathrm{kdim}(A/\mathfrak{p}) = \mathrm{trdeg}(A/\mathfrak{p})$. If now $\mathfrak{p} \subseteq \mathfrak{q}$ are nested primes in A, then choose a maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} A$ such that $\mathfrak{q} \trianglelefteq_{\mathrm{i}} \mathfrak{m}$. Then $(\mathfrak{p},\mathfrak{q},\mathfrak{m})$ is a CPI in A - if $\mathfrak{p}=\mathfrak{q}$ or $\mathfrak{q}=\mathfrak{m}$ just omit one of the duplicates. By the correspondence theorem

$$0 \;=\; \mathfrak{p}\Big/\mathfrak{p} \;\subseteq\; \mathfrak{q}\Big/\mathfrak{p} \;\subseteq\; \mathfrak{m}\Big/\mathfrak{p}$$

is a CPI in $A/\mathfrak{p}$ (except for duplicates). As $\mathrm{kdim}(A/\mathfrak{p}) \leq \mathrm{kdim}(A) < \infty$ we can append this chain to a maximal CPI in $A/\mathfrak{p}$. Let $(\mathfrak{u}_0,\ldots,\mathfrak{u}_r,\ldots,\mathfrak{u}_m)$ be that CPI, where $\mathfrak{u}_0 = \mathfrak{p}/\mathfrak{p}$, $\mathfrak{u}_r = \mathfrak{q}/\mathfrak{p}$ and $\mathfrak{u}_m = \mathfrak{m}/\mathfrak{p}$. In particular $(\mathfrak{u}_0,\ldots,\mathfrak{u}_r)$ is saturated and thereby uniquely determined to be

$$r \;=\; \mathrm{kdim}\left(A\Big/\mathfrak{p}\right) - \mathrm{kdim}\left(A\Big/\mathfrak{q}\right)$$

by (8.75.(ii)). Conversely, if $(\mathfrak{q}_0,\ldots,\mathfrak{q}_s)$ another saturated CPI of A with $\mathfrak{q}_0=\mathfrak{p}$ and $\mathfrak{q}_s=\mathfrak{q}$, then (8.75.(ii)) also tells us $s=r$. That is there is a CPI connecting $\mathfrak{p}$ and $\mathfrak{q}$ and the length of any such sturated chain, is uniquely determined. In other words A is catenary.

(iv) The first part $\mathrm{kdim}(A) = n$ has already been proved in (ii). We go a little further: As $\{\, z_1,\ldots,z_n \,\}$ is algebraically independent $P = E[z_1,\ldots,z_n]$ is isomorphic to a polynomial ring in n variables over E. But as such it even is an UFD - by the lemma of Gauss (7.29.(iv)) - and hence a normal domain - due to (2.65). We will require this for the proof of $\mathrm{height}(\mathfrak{a}_i) = k(i)$ for any $i \in 1\ldots r$:

For any $k \in 0\ldots n$ let us denote $\mathfrak{p}_k := z_1P + \cdots + z_kP \trianglelefteq_{\mathrm{i}} P$. That is $\mathfrak{p}_k$ is the ideal generated by $\{\, z_1,\ldots,z_k \,\}$. And therefore we have $\mathrm{height}(\mathfrak{p}_k) = k$ by (8.77.(ii)). Yet as $A:P$ is finite, it also

is integral and P is a normal domain, as we have argued above. And as A is an integral domain it also is torsion-free, as a P-module. Therefore we can invoke (8.73.(iv)) to find the desired identity

$$\text{height}\big(\mathfrak{a}_i\big) \;=\; \text{height}\big(\mathfrak{a}_i \cap P\big) \;=\; \text{height}\big(\mathfrak{p}_{k(i)}\big) \;=\; k(i)$$

□

Proof of (8.78):

(i) As A is an E-algebra, so is $A_\mathfrak{p}$ under $a(f/u) = (af)/u$. And therefore the quotient $A_\mathfrak{p}/\mathfrak{p}A_\mathfrak{p}$ is an E-algebra, too. Also note that due to (2.138) we have the following isomorphy

$$E_\mathfrak{p} \;=\; A_\mathfrak{p}\Big/_{\mathfrak{p}A_\mathfrak{p}} \;\xrightarrow{\sim}\; \text{QUOT}\left(A\Big/_\mathfrak{p}\right) \;:\; \frac{f}{u} + \mathfrak{p}A_\mathfrak{p} \mapsto \frac{f+\mathfrak{p}}{u+\mathfrak{p}}$$

And as $\mathfrak{p}$ is a prime ideal $A/\mathfrak{p}$ is an integral domain, such that $\text{kdim}(A/\mathfrak{p}) = \text{trdeg}(A/\mathfrak{p} : E)$ because of (8.76.(i)). But the transcendence degree remains unchanged, when going to quotient fields, due to (8.49.(ii)). Then we finally use the isomorphisms of $E_\mathfrak{p}$ and $E = \text{QUOT}(E)$ to find the following identity, in the end:

$$\text{kdim}\left(A\Big/_\mathfrak{p}\right) \;=\; \text{trdeg}\left(A\Big/_\mathfrak{p} : E\right) \;=\; \text{trdeg}\left(\text{QUOT}\left(A\Big/_\mathfrak{p}\right) : \text{QUOT}(E)\right) \;=\; \text{trdeg}(E_\mathfrak{p} : E)$$

(ii) Consider a minimal prime ideal $\mathfrak{p}_* \in \text{Smin}(A)$ such that $\mathfrak{p}_* \subseteq \mathfrak{p}$ and append $(\mathfrak{p}_*, \mathfrak{p})$ to a maximal CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$ of A. As $\mathfrak{p}_*$ is a minimal prime ideal, we have $\mathfrak{p}_0 = \mathfrak{p}_*$. Then by (8.76.(iii)) we find

$$r \;=\; \text{kdim}\left(A\Big/_{\mathfrak{p}_*}\right) - \text{kdim}\left(A\Big/_{\mathfrak{p}_r}\right)$$

Also $\mathfrak{p}_r$ is a maximal ideal, as the CPI, was maximal, thus $A/\mathfrak{p}_r$ is a field. In particular the Krull-dimension of $A/\mathfrak{p}_r$ is 0 and hence the above equality turns into

$$\text{kdim}\left(A\Big/_{\mathfrak{p}_*}\right) \;=\; r \;\leq\; \sup\left\{ \ell(\mathcal{P}) \;\middle|\; \begin{array}{l} \mathcal{P} \in \text{CPI}(A) \\ \text{with } \mathfrak{p} \in \mathcal{P} \end{array} \right\}$$

As this is true for any minimal prime ideal $\mathfrak{p}_*$ contained in $\mathfrak{p}$ this already means that the maximal Krull dimension of $A/\mathfrak{p}_*$ cannot exceed the supremum of the length of chains containing $\mathfrak{p}$

$$\max\left\{ \text{kdim}\left(A\Big/_{\mathfrak{p}_*}\right) \;\middle|\; \begin{array}{l} \mathfrak{p}_* \in \text{Smin}(A) \\ \text{with } \mathfrak{p}_* \subseteq \mathfrak{p} \end{array} \right\} \;\leq\; \sup\left\{ \ell(\mathcal{P}) \;\middle|\; \begin{array}{l} \mathcal{P} \in \text{CPI}(A) \\ \text{with } \mathfrak{p} \in \mathcal{P} \end{array} \right\}$$

Conversely let $\mathcal{P} = (\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$ be a CPI of A containing $\mathfrak{p} \in \mathcal{P}$. As we need to control the length of $\mathcal{P}$ anyway, we may assume $\mathcal{P}$ to be maximal already. Thus $\mathfrak{p}_0 \in \text{Smin}(A)$ is a minimal ideal and $\mathfrak{p} \in \mathcal{P}$ this yields $\mathfrak{p}_0 \subseteq \mathfrak{p}$. By going to quotients $/\mathfrak{p}_0$ we turn to

$$0 \;=\; \mathfrak{p}_0\Big/_{\mathfrak{p}_0} \;\subset\; \mathfrak{p}_1\Big/_{\mathfrak{p}_0} \;\subset\; \ldots \;\subset\; \mathfrak{p}_r\Big/_{\mathfrak{p}_0}$$

which is a (maximal) CPI in $A/\mathfrak{p}_0$ of length r. In particular its length r cannot exceed $\text{kdim}(A/\mathfrak{p}_0)$

and therefore we also have the converse inequality and therefore

$$\max\left\{ \operatorname{kdim}\left(A\Big/\mathfrak{p}_*\right) \;\middle|\; \begin{array}{l}\mathfrak{p}_* \in \operatorname{Smin}(A)\\ \text{with } \mathfrak{p}_* \subseteq \mathfrak{p}\end{array} \right\} \;=\; \sup\left\{ \ell(\mathcal{P}) \;\middle|\; \begin{array}{l}\mathcal{P} \in \operatorname{CPI}(A)\\ \text{with } \mathfrak{p} \in \mathcal{P}\end{array} \right\}$$

- It remains to prove, that this also equals $\operatorname{kdim}(A/\mathfrak{p}) + \operatorname{height}(\mathfrak{p})$: Thus consider any CPI $\mathcal{P} = (\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$ of A such that $\mathfrak{p} \in \mathcal{P}$ and $\mathcal{P}$ is of maximal length, with this property. Say $\mathfrak{p} = \mathfrak{p}_k$ for some $k \in 0 \ldots n$. In particular $\mathfrak{p}_r$ is a maximal ideal, else we could append a maximal ideal containing $\mathfrak{p}_r$ to obtain a CPI of length $r+1$, also containing $\mathfrak{p}$. This is impossible, as we chose r to be maximal. Then $A/\mathfrak{p}_r$ is a field and hence $\operatorname{kdim}(A/\mathfrak{p}_r) = 0$ again, such that by (8.76.(iii))

$$\operatorname{kdim}\left(A\Big/\mathfrak{p}\right) \;=\; \operatorname{kdim}\left(A\Big/\mathfrak{p}_k\right) - \operatorname{kdim}\left(A\Big/\mathfrak{p}_r\right) \;=\; r-k$$

 That is $\operatorname{kdim}(A/\mathfrak{p}) + k = r$. As $(\mathfrak{p}_0, \ldots, \mathfrak{p}_k)$ is a CPI ending in $\mathfrak{p} = \mathfrak{p}_k$ we have $k \leq \operatorname{height}(\mathfrak{p})$. Suppose we had $k < \operatorname{height}(\mathfrak{p})$, that is there was SOME CPI $(\mathfrak{q}_0, \ldots, \mathfrak{q}_m)$ such that $\mathfrak{q}_m = \mathfrak{p}$ and $m > k$. But this would mean that $(\mathfrak{q}_0, \ldots, \mathfrak{q}_m, \mathfrak{p}_{k+1}, \ldots, \mathfrak{p}_r)$ would be a CPI of length $r + m - k > r$ containing $\mathfrak{p}$, contradicting the maximality of r, again. Thus we have $k = \operatorname{height}(\mathfrak{p})$ and hence $r = \operatorname{kdim}(A/\mathfrak{p}) + \operatorname{height}(\mathfrak{p})$. And as r was the supremum, the third equality is established.

(iii) Let us first check (1), that $\{\, \overline{z}_{k+1}, \ldots, \overline{z}_n \,\}$ are algebraically independent. That is we regard any polynomial $f \in E[t_{k+1}, \ldots, t_n]$ such that $f(\overline{z}_{k+1}, \ldots, \overline{z}_n) = 0 + \mathfrak{p}$. As $x \mapsto \overline{x}$ is a homomorphism of E-algebras, this means $f(z_{k+1}, \ldots, z_n) + \mathfrak{p} = 0 + \mathfrak{p}$ and hence $f(z_{k+1}, \ldots, z_n) \in \mathfrak{p}$. As also $f(z_{k+1}, \ldots, z_n) \in E[z_1, \ldots, z_n] = P$ we then get

$$f(z_{k+1}, \ldots, z_n) \;\in\; \mathfrak{p} \cap P \;=\; z_1 P + \cdots + z_k P$$

 That is $f(z_{k+1}, \ldots, z_n) \in E[z_{k+1}, \ldots, z_n] \cap E[z_1, \ldots, z_k] = E$. As f cannot be constant $f \in E^*$ there only remains $f = 0$, which is the algebraic independence of $\{\, \overline{z}_{k+1}, \ldots, \overline{z}_n \,\}$.

- Let us prove (4) next: Note that the canonical epimorphism $\varrho : A \twoheadrightarrow A/\mathfrak{p} : x \mapsto x + \mathfrak{p}$ maps $\varrho(z_j) = 0 + \mathfrak{p}$ for $j \in 1 \ldots k$, as $z_j \in \mathfrak{p} \cap P \subseteq \mathfrak{p}$ and $\varrho(z_j) = \overline{z}_j$ for $j \in k+1 \ldots n$, by construction. Thus, for any element $f(z_1, \ldots, z_n) \in P$ we find

$$f(z_1, \ldots, z_n) + \mathfrak{p} \;=\; f\big(0, \ldots, 0, \overline{z}_{k+1}, \ldots, \overline{z}_n\big)$$

 In particular $\varrho(P) = E[\overline{z}_{k+1}, \ldots, \overline{z}_n]$. Let us take a look at the kernel of ϱ in P: From the above identity it is clear, that $f(z_1, \ldots, z_n) + \mathfrak{p} = 0$ iff $f(z_1, \ldots, z_n) \in z_1 P + \cdots + z_k P = \mathfrak{p} \cap P$. That is the restriction of ϱ to P induces the desired isomorphism, by the first isomorphism theorem

$$P\Big/\mathfrak{p} \cap P \;\xrightarrow{\sim}\; E[\overline{z}_{k+1}, \ldots, \overline{z}_n] \;:\; f(z_1, \ldots, z_n) + \mathfrak{p} \cap P \mapsto f(z_1, \ldots, z_n) + \mathfrak{p}$$

- For property (2) we note, that $A : P$ is finite and by (4) we know $\varrho(P) = E[\overline{z}_{k+1}, \ldots, \overline{z}_n] = \overline{P}$. Therefore we can conclude that $A/\mathfrak{p} : \overline{P}$ is finite, by (8.28). And now, that $A/\mathfrak{p} : \overline{P}$ is finite, it also is integral. Thus we have $\operatorname{kdim}(A/\mathfrak{p}) = \operatorname{kdim}(\overline{P})$, according to (8.73.(i)). But as $\{\, \overline{z}_{k+1}, \ldots, \overline{z}_n \,\}$ is algebraically independent $\overline{P}$ is isomorphic to a polynomial ring in $n-k$ variables over the field E and hence $\operatorname{kdim}(A/\mathfrak{p}) = \operatorname{kdim}(\overline{P}) = n - k$.

- It remains to prove (5): As for any $j \in 1 \ldots k$ we have $z_j \in \mathfrak{p} \cap P \subseteq \mathfrak{a}_1 \cap P = z_1 P + \cdots + z_{k(1)} P$ we conclude $j \leq k(i)$, as the $z_1 P + \cdots + z_i P$ form a CPI in P. Therefore $k \leq k(1)$. And for $j \in k+1 \ldots k(i)$ we have $z_j \in z_j P \subseteq \mathfrak{a}_i \cap P$ such that $\overline{z}_j = z_j + \mathfrak{p} = \varrho(z_j) \in (\mathfrak{a}_i/\mathfrak{p}) \cap \varrho(P)$ where $\varrho(P) = \overline{P}$, as we have seen in (4). Thus we have found the inclusion

$$\overline{z}_{k+1}\overline{P} + \cdots + \overline{z}_{k(i)}\overline{P} \quad \subseteq \quad \mathfrak{a}_i \Big/ \mathfrak{p} \cap \overline{P}$$

In the converse direction we start with some some $\overline{x} = x + \mathfrak{p} \in \mathfrak{a}_i/\mathfrak{p} \cap \overline{P}$. That is $x \in \mathfrak{a}_i$ and $x + \mathfrak{p} = \varrho(x) \in \overline{P} = \varrho(P)$. The latter is $x \in P$ and thereby $x \in \mathfrak{a}_i \cap P = z_1 P + \cdots + z_{k(i)} P$ by assumption. But then $\varrho(x) \in \sum_j \varrho(z_j)\overline{P}$ and we have already seen $\varrho(z_j) = 0$ for $j \in 1 \ldots k$. Thus it only remains $x + \mathfrak{p} = \varrho(x) \in \sum_j \varrho(z_j)\overline{P}$ where the sum runs from $j = k+1$ to $j = n$. Thus we also have the converse inclusion.

□

Proof of (8.79):

(i) From the definition it is clear, that $\operatorname{trdeg}(A : E) \leq \operatorname{tfree}(A : E)$, as any transcendence basis $U \subseteq A$ already has to be algebraically independent. Now let $U \subseteq A$ be be any algebraically independent set. As A is an integral domain, we find a transcendence basis $V \subseteq A$ with $U \subseteq V$, according to (8.47.(i)). In particular $\#U \leq \#V = \operatorname{trdeg}(A : E)$ and thereby $\operatorname{tfree}(A : E) \leq \operatorname{trdeg}(A : E)$, too.

(ii) As $\mathfrak{q} \trianglelefteq_{\mathfrak{i}} A$ is prime, $A/\mathfrak{q}$ is an integral domain. Hence we may choose a transcendence basis of $A/\mathfrak{q} : E$, say $\{ u_i + \mathfrak{q} \mid i \in I \} \subseteq a/\mathfrak{q}$. Then we let $U := \{ u_i \mid i \in I \}$ and claim, that U is algebraically independent. Consider any $u_1, \ldots, u_n \in U$ and some polynomial $f \in E[t_1, \ldots, t_n]$ such that $f(u_1, \ldots, u_n)$, then we also get

$$f(u_1 + \mathfrak{q}, \ldots, u_n + \mathfrak{q}) \;=\; f(u_1, \ldots, u_n) + \mathfrak{q} \;=\; 0 + \mathfrak{q}$$

But as the $u_i + \mathfrak{q}$ are algebraically independent, we conclude $f = 0$ from this equality. And thereby $\{ u_1, \ldots, u_n \}$ is algebraically independent. As this is true for any finite subset, U itself is algebraically independent. And thereby $\operatorname{tfree}(A/\mathfrak{q} : E) = \operatorname{trdeg}(A/\mathfrak{q} : E) = \#I \leq \operatorname{tfree}(A : E)$.

(iii) This proof will take several steps: First of all, let A be a finite-dimensional integral domain. Then we pick up a CPI $\mathfrak{q}_0 \subset \ldots \subset \mathfrak{q}_r$ in A of length $r = \operatorname{kdim}(A)$. As the inclusions are strict, we can pick some elements $x_i \in A$ such that

$$x_i \quad \in \quad \mathfrak{q}_i \setminus \mathfrak{q}_{i-1}$$

for any $i \in 1 \ldots r$. Now let $P := E[x_1, \ldots, x_r] \subseteq A$. As A is an integral domain, so is P. And by construction P is finitely generated. Thus we get from (8.76.(i)) and (i) we get

$$\operatorname{kdim}(P) \;=\; \operatorname{trdeg}(P : E) \;=\; \operatorname{tfree}(P : E)$$

Now let $\mathfrak{p}_i := \mathfrak{q}_i \cap P$, then it is clear that these ideals form an ascending chain $\mathfrak{p}_0 \subseteq \ldots \subseteq \mathfrak{p}_r$. But as $x_i \in \mathfrak{q}_i \cap P = \mathfrak{p}_i$ though $x_i \notin \mathfrak{q}_{i-1}$ we find that these inclusions are strict $\mathfrak{p}_0 \subset \ldots \subset \mathfrak{p}_r$

even. In particular the Krull-dimension of P is r at least

$$r \;\leq\; \mathrm{kdim}(P) \;=\; \mathrm{trdeg}(P:E)$$

As $E[t_1,\ldots,t_r] \twoheadrightarrow P$ we even get $\mathrm{kdim}(P) = r$, but we actually do not need this here. Recall that we took $r = \mathrm{kdim}(A)$. And as all E, P and A are integral domains we have (8.49.(iii)) which yields the desired inequality

$$\mathrm{kdim}(A) \;=\; r \;=\; \mathrm{trdeg}(P:E) \;\leq\; \mathrm{trdeg}(A:P) + \mathrm{trdeg}(P:E) \;=\; \mathrm{trdeg}(A:E)$$

- If A is an integral domain with $\mathrm{kdim}(A) = \infty$, then there are CPI of unbound length r in A. And by the construction above, this can be turned into $r \leq \mathrm{trdeg}(A:E)$. Thus $\mathrm{trdeg}(A:E)$ is unbound, too and hence $\mathrm{trdeg}(A:E) = \infty = \mathrm{kdim}(A)$.

- Now consider a finite-dimensional E-algebra A, that may contain zero-divisors. Again let $\mathfrak{q}_0 \subset \ldots \subset \mathfrak{q}_r$ be a CPI in A with $r = \mathrm{kdim}(A)$. By the correspondence theorem (8.65.(i)) we get the CPI $0 = \mathfrak{q}_0/\mathfrak{q}_0 \subset \ldots \subset \mathfrak{q}_r/\mathfrak{q}_0$ in $A/\mathfrak{q}_0$ and thereby $\mathrm{kdim}(A\mathfrak{q}_0) \geq r$. But also $\mathrm{kdim}(A/\mathfrak{q}_0) \leq \mathrm{kdim}(A) = r$ by (8.69.(x)). Together this is $\mathrm{kdim}(A/\mathfrak{q}_0) = r = \mathrm{kdim}(A)$. But $A/\mathfrak{q}_0$ is an integral domain, too, such by the step above and (ii) we can conclude

$$\mathrm{kdim}(A) \;=\; r \;=\; \mathrm{kdim}\left(A\Big/\mathfrak{q}_0\right) \;\leq\; \mathrm{tfree}\left(A\Big/\mathfrak{q}_0 : E\right) \;\leq\; \mathrm{tfree}(A:E)$$

- Let finally A be an E-algebra of $\mathrm{kdim}(A) = \infty$, that may contain zero-divisors. then there are CPI of unbound length r in A. And by the construction above, this can be turned into $r \leq \mathrm{tfree}(A:E)$. Thus $\mathrm{tfree}(A:E)$ is unbound, too and hence $\mathrm{tfree}(A:E) = \infty = \mathrm{kdim}(A)$.

(iv) By (iii) we know $\mathrm{kdim}(P) \leq \mathrm{tfree}(P:E)$ and as $P \subseteq A$ any algebraically independent $U \subseteq P$ also is an algebraically subset $U \subseteq A$. Thus we have $\mathrm{tfree}(P:E) \leq \mathrm{tfree}(A:E)$. But as A is an integral domain we have $\mathrm{free}(A:E) = \mathrm{trdeg}(A:E)$ and as A also is finitely generated by (8.76.(i)) $\mathrm{trdeg}(A:E) = \mathrm{kdim}(A)$. Altogether that is

$$\mathrm{kdim}(P) \;\leq\; \mathrm{tfree}(P:E) \;\leq\; \mathrm{tfree}(A:E) \;=\; \mathrm{trdeg}(A:E) \;=\; \mathrm{kdim}(A)$$

□

Proof of (8.80):

(i) **Claim:** Let R be a noetherian, local integral domain with maximal ideal $\mathfrak{p}$. Also let $a \in R$ be an element with $a \neq 0$ and $\mathfrak{p}$ also is a minimal prime ideal over aR. Then $\mathrm{height}(\mathfrak{p}) = 1$, that is: If $\mathfrak{p}_0 \in \mathrm{Spec}(R)$ is another prime ideal satisfying $0 \subseteq \mathfrak{p}_1 \subset \mathfrak{p}$, then we already have $\mathfrak{p}_1 = 0$.

- **Proof:** By assumption $\mathfrak{p}$ is the one and only maximal ideal of R and hence $\mathrm{JAC}(R) = \mathfrak{p}$. Also $\mathfrak{p}$ is a minimal prime ideal over $\mathfrak{a} := aR \trianglelefteq_{\mathrm{i}} R$. Suppose we had $a \in \mathfrak{p}_1$ then $\mathfrak{a} \subseteq \mathfrak{p}_1 \subset \mathfrak{p}$. As $\mathfrak{p}$ is minimal over $\mathfrak{a}$ we would get $\mathfrak{p}_1 = \mathfrak{p}$, which is untrue. Therefore we find $a \notin \mathfrak{p}_1$.

 Now take to the quotient ring $R/\mathfrak{a}$. We will argue, that $R/\mathfrak{a}$ has one and one prime ideal only $\mathrm{Spec}(R/\mathfrak{a}) = \{\,\mathfrak{p}/\mathfrak{a}\,\}$: Consider any prime ideal $\mathfrak{u}$ of $R/\mathfrak{a}$. Then $\mathfrak{u}$ is of the form $\mathfrak{u} = \mathfrak{p}'/\mathfrak{a}$ for

some $\mathfrak{p}' \in \mathrm{Spec}(R)$ with $\mathfrak{a} \subseteq \mathfrak{p}'$. But as $\mathfrak{p}' \neq R$ is a proper ideal, it is contained in a maximal ideal, by (2.4.(ii)). But the only maximal ideal available in R is $\mathfrak{p}$ such that we get $\mathfrak{a} \subseteq \mathfrak{p}' \subseteq \mathfrak{p}$. As $\mathfrak{p}$ is minimal over $\mathfrak{a}$ we conclude $\mathfrak{p}' = \mathfrak{p}$ again. In particular

$$\mathrm{kdim}\left(R \Big/ \mathfrak{a}\right) \;=\; 0$$

as we don't even have a second prime ideal to build a chain with. But as quotients of a noetherian ring R are noetherian again, so is $R/\mathfrak{a}$. But zero-dimensional noetherian rings are artinian, by (2.37.(e)). We now make use of the *symbolic powers* $\mathfrak{p}_1^{(n)}$ of $\mathfrak{p}_1$. As $R/\mathfrak{a}$ is artinian the following descending chain of ideals in R

$$\mathfrak{p}_1^{(0)} + \mathfrak{a} \;\supseteq\; \mathfrak{p}_1^{(1)} + \mathfrak{a} \;\supseteq\; \mathfrak{p}_1^{(2)} + \mathfrak{a} \;\supseteq\; \mathfrak{p}_1^{(3)} + \mathfrak{a} \;\supseteq\; \ldots$$

has to stabilize, as it corresponds to a chain of ideals in $R/\mathfrak{a}$. That is there is some $n \in \mathbb{N}$ such that $\mathfrak{p}_1^{(n+1)} + \mathfrak{a} = \mathfrak{p}_1^{(n)} + \mathfrak{a}$. In particular $\mathfrak{p}_1^{(n)} \subseteq \mathfrak{p}_1^{(n+1)} + \mathfrak{a} = \mathfrak{p}_1^{(n+1)} + aR$. In the next step we will prove that for this n we get the identity

$$\mathfrak{p}_1^{(n)} \;=\; \mathfrak{p}_1^{(n+1)} + \mathfrak{p}\,\mathfrak{p}_1^{(n)}$$

- As both $\mathfrak{p}_1^{(n+1)} \subseteq \mathfrak{p}_1^{(n)}$ and $\mathfrak{p}\,\mathfrak{p}_1^{(n)} \subseteq \mathfrak{p}_1^{(n)}$ the inclusion from right to left is clear. For the converse inclusion we start with any $p \in \mathfrak{p}_1^{(n)}$. As we already have $\mathfrak{p}_1^{(n)} \subseteq \mathfrak{p}_1^{(n+1)} + aR$ there are some elements $q \in \mathfrak{p}_1^{(n+1)}$ and $r \in R$ such that $p = q + ar$. In particular $q \in \mathfrak{p}_1^{(n+1)} \subseteq \mathfrak{p}_1^{(n)}$ such that $ar = p - q \in \mathfrak{p}_1^{(n)}$. But by (2.92.(iii)) $\mathfrak{p}_1^{(n)}$ is a $\mathfrak{p}_1$ primary ideal. And as $ar \in \mathfrak{p}_1^{(n)}$ but $a \notin \mathfrak{p}_1 = \sqrt{\mathfrak{p}_1^{(n)}}$ we hence get $r \in \mathfrak{p}_1^{(n)}$. That is we have $p = q + ar \in \mathfrak{p}_1^{(n+1)} + \mathfrak{p}\,\mathfrak{p}_1^{(n)}$ since $a \in \mathfrak{p}$. And this is the inclusion from left to right.
- Consider $M := \mathfrak{p}_1^{(n)}$ as an R-module and $P := \mathfrak{p}_1^{(n+1)}$ a sub-module of M. As R is noetherian, M is finitely generated and we have just proved $M = P + \mathfrak{p}M$. Recall $\mathfrak{p} = \mathrm{JAC}(R)$, then the lemma of Nakayama (3.44.(iii)) tells us $P = M$, that is $\mathfrak{p}_1^{(n+1)} = \mathfrak{p}_1^{(n)}$. Then we can use (2.92.(iv)) to compute

$$\mathfrak{p}_1^n\, R_{\mathfrak{p}_1} \;=\; \mathfrak{p}_1^{(n)}\, R_{\mathfrak{p}_1} \;=\; \mathfrak{p}_1^{(n+1)}\, R_{\mathfrak{p}_1} \;=\; \mathfrak{p}_1^{n+1}\, R_{\mathfrak{p}_1}$$

 But by (8.21.(ii)) we also have $\mathfrak{p}_1^{n+1}\, R_{\mathfrak{p}_1} = \big(\mathfrak{p}_1\mathfrak{p}_1^n\big) R_{\mathfrak{p}_1} = \big(\mathfrak{p}_1\, R_{\mathfrak{p}_1}\big)\big(\mathfrak{p}_1^n\, R_{\mathfrak{p}_1}\big)$. Note that $R_{\mathfrak{p}_1}$ is a local ring with maximal ideal $\mathfrak{j} := \mathfrak{p}_1\, R_{\mathfrak{p}_1}$ - that is this ideal also is the Jacobson-radical of $R_{\mathfrak{p}_1}$. So if we consider the ideal $M := \mathfrak{p}_1^n\, R_{\mathfrak{p}_1}$ as an R-module again, we have $M = \mathfrak{p}_1^{n+1}\, R_{\mathfrak{p}_1} = \mathfrak{j}M$, such that another dose of the lemma of Nakayama (3.44.(ii)) leaves us with $\mathfrak{p}_1^n\, R_{\mathfrak{p}_1} = M = 0$.
- Now suppose we had $\mathfrak{p}_1 \neq 0$, that is there is some $p \in \mathfrak{p}_1$ with $p \neq 0$. Then we had $p^n \in \mathfrak{p}_1^n$ and as R is an integral domain, also $p^n \neq 0$. Therefore $p^n/1 \in \mathfrak{p}_1^n\, R_{\mathfrak{p}_1}$ also is $p^n/1 \neq 0/1$ non-zero, as $up^n = 0$ would mean $0 = u \in R \setminus \mathfrak{p}_1$. But this contradicts $\mathfrak{p}_1^n\, R_{\mathfrak{p}_1} = 0$, such we have to settle with $\mathfrak{p}_1 = 0$ and this has been claimed, above.
- **Proof** of (i) in general: We have to show $\mathrm{height}(\mathfrak{p}) \leq 1$, so consider a CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$ of R with $\mathfrak{p}_r = \mathfrak{p}$. If $a \in \mathfrak{p}_0$ there is not much to do: As $aR \subseteq \mathfrak{p}_0 \subseteq \mathfrak{p}$ and $\mathfrak{p}$ is minimal over aR we have $\mathfrak{p}_0 = \mathfrak{p}$ and thereby $r = 0$. Such a chain is of length 0. In case $a \notin \mathfrak{p}_0$ we continue: Consider the setup $\mathfrak{p}_0 \subseteq \mathfrak{p}_1 \subset \mathfrak{p}$, then we will prove $\mathfrak{p}_0 = \mathfrak{p}_1$. From this we conclude that the above CPI

can be $(\mathfrak{p}_0, \mathfrak{p}_1)$ with $\mathfrak{p}_1 = \mathfrak{p}$ at most and hence $r \leq 1$ in this case. In both cases we then have height$(\mathfrak{p}) \leq 1$, which is the claim.

As $a \in \mathfrak{p}_0$ is done with, we regard $a \notin \mathfrak{p}_0$. In this case we take to the quotient ring $Q := R/\mathfrak{p}_0$ which is an integral domain and clearly is noetherian again - if $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ is generated by $\mathfrak{a} = \langle a_1, \ldots, a_n \rangle_{\mathfrak{i}}$ and $\mathfrak{p} \subseteq \mathfrak{a}$, then $\mathfrak{a}/\mathfrak{p}$ is generated by $\langle a_1 + \mathfrak{p}, \ldots, a_n + \mathfrak{p} \rangle_{\mathfrak{i}}$. The chain $\mathfrak{p}_0 \subseteq \mathfrak{p}_1 \subset \mathfrak{p}$ then turns into the following chain in Q

$$0 \;=\; \mathfrak{p}_0 \Big/ \mathfrak{p}_0 \;\subseteq\; \mathfrak{p}_1 \Big/ \mathfrak{p}_0 \;\subset\; \mathfrak{p} \Big/ \mathfrak{p}_0$$

Let us abbreviate $\overline{\mathfrak{p}} := \mathfrak{p}/\mathfrak{p}_0$. As $a \notin \mathfrak{p}_0$ we have $0 \neq a + \mathfrak{p}_0 \in \overline{\mathfrak{p}}$ such that $\overline{\mathfrak{p}} \neq 0$ is non-zero. Now we continue to $Q_{\overline{\mathfrak{p}}}$ which is a local ring by (2.138) and a noetherian integral domain by (2.131). And the above chain turns into a chain of prime ideals in $Q_{\overline{\mathfrak{p}}}$

$$0 \;=\; \mathfrak{p}_0 \Big/ \mathfrak{p}_0 Q_{\overline{\mathfrak{p}}} \;\subseteq\; \mathfrak{p}_1 \Big/ \mathfrak{p}_0 Q_{\overline{\mathfrak{p}}} \;\subset\; \mathfrak{p} \Big/ \mathfrak{p}_0 Q_{\overline{\mathfrak{p}}}$$

Again, as $\overline{a} := a + \mathfrak{p} \neq 0 + \mathfrak{p}$ we get $\overline{a}/\overline{1} \neq \overline{0}/\overline{1}$. Suppose there was a prime ideal in between $\overline{a}/\overline{1}\, Q_{\overline{\mathfrak{p}}}$ and $\overline{\mathfrak{p}}\, Q_{\overline{\mathfrak{p}}}$. Then by (8.65.(iii)) this prime ideal would correspond to a prime ideal $\mathfrak{p}'$ in R, strictly underneath $\mathfrak{p}$. This ideal would be of the form $\overline{\mathfrak{p}}'\, Q_{\overline{\mathfrak{p}}}$ for some $\mathfrak{p}' \in \operatorname{Spec}(R)$. And as $\overline{a}/\overline{1} \in \overline{\mathfrak{p}}'\, Q_{\overline{\mathfrak{p}}}$ we had $\overline{a} \in \overline{\mathfrak{p}}'$ and thereby $a \in \mathfrak{p}'$. That is we had the chain $aR \subseteq \mathfrak{p}' \subset \mathfrak{p}$, but as $\mathfrak{p}$ is a minimal prime ideal over aR, there is no such $\mathfrak{p}'$ and hence $\overline{\mathfrak{p}}\, Q_{\overline{\mathfrak{p}}}$ is a minimal prime ideal over $\overline{a}/\overline{1}\, Q_{\overline{\mathfrak{p}}}$.

Now $Q_{\overline{\mathfrak{p}}}$ and $\overline{\mathfrak{p}}\, Q_{\overline{\mathfrak{p}}}$ satisfy the properties required in the claim above. Looking at the chain of prime ideals in $Q_{\overline{\mathfrak{p}}}$ above, we conclude that $\mathfrak{p}_1/\mathfrak{p}_0\, Q_{\overline{\mathfrak{p}}} = 0$. But this means $\mathfrak{p}_1/\mathfrak{p}_0 = 0$ by the correspondence theorem (2.129) which is the claim we needed: We have arrived, at $\mathfrak{p}_0 = \mathfrak{p}_1$ from which we conclude $r \leq 1$.

(iv) Let us conduct this proof by induction on r: For $r = 1$ there is nothing to prove, the claim equals the assumption. So let us consider the case $r = 2$: If $a \in \mathfrak{p}_1$ already, then we are done. Else take to the quotient ring $Q := R/\mathfrak{p}_0$ and regard the chain

$$0 \;=\; \mathfrak{p}_0 \Big/ \mathfrak{p}_0 \;\subset\; \mathfrak{p}_1 \Big/ \mathfrak{p}_0 \;=\; \mathfrak{p}_2 \Big/ \mathfrak{p}_0$$

We have $(a + \mathfrak{p}_0)Q \subseteq \mathfrak{p}_2/\mathfrak{p}_0$ by assumption and hence there is a prime ideal, minimal over $(a + \mathfrak{p}_0)Q$ contained in $\mathfrak{p}_2/\mathfrak{p}_0$, according to (2.18.(iv)). This ideal is of the form $\widetilde{\mathfrak{p}}_1/\mathfrak{p}_0$ for some prime ideal $\widetilde{\mathfrak{p}}_1$ of R with $\mathfrak{p}_0 \subseteq \widetilde{\mathfrak{p}}_1$. As $\widetilde{\mathfrak{p}}_1/\mathfrak{p}_0 \subseteq \mathfrak{p}_2/\mathfrak{p}_0$ we get $\widetilde{\mathfrak{p}}_1 \subseteq \mathfrak{p}_2$ so by now we have

$$\mathfrak{p}_0 \;\subseteq\; \widetilde{\mathfrak{p}}_1 \;\subseteq\; \mathfrak{p}_2$$

Clearly $a \in \widetilde{\mathfrak{p}}_1$ as $a + \mathfrak{p}_0 \in \widetilde{\mathfrak{p}}_1/\mathfrak{p}_0$. And as $a + \mathfrak{p}_0 \neq 0 + \mathfrak{p}_0$ we have $a \in \widetilde{\mathfrak{p}}_1 \setminus \mathfrak{p}_0$ such that $\mathfrak{p}_0 \subset \widetilde{\mathfrak{p}}_1$. And as $\widetilde{\mathfrak{p}}_1/\mathfrak{p}_0$ is minimal over $(a + \mathfrak{p}_0)Q$ we have height$(\widetilde{\mathfrak{p}}_1/\mathfrak{p}_0) \leq 1$, as we have just proved in (i). But height$(\mathfrak{p}_2/\mathfrak{p}_0) \geq 2$, as we startet with a chain of length 2, Thus we also have $\widetilde{\mathfrak{p}}_1 \neq \mathfrak{p}_2$ which amounts to $\widetilde{\mathfrak{p}}_1 \subset \mathfrak{p}_2$. Thus we have found our CPI and rest the case $r = 2$

$$\mathfrak{p}_0 \;\subset\; \widetilde{\mathfrak{p}}_1 \;\subset\; \mathfrak{p}_2$$

For a general $r \geq 3$ we are given a CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$ of R with $a \in \mathfrak{p}_r$. Thus we can use the induction hypothesis on the truncated chain $(\mathfrak{p}_1, \ldots, \mathfrak{p}_r)$ and find $\widetilde{\mathfrak{p}}_k$ where $k \in 2 \ldots r-1$ such that $a \in \widetilde{\mathfrak{p}}_2$. But then we can also look at $(\mathfrak{p}_0, \mathfrak{p}_1, \widetilde{\mathfrak{p}}_2)$. By the case $r = 2$ there is another prime ideal $\widetilde{\mathfrak{p}}_1$ with $a \in \widetilde{\mathfrak{p}}_2$. And thus we have found the chain $(\mathfrak{p}_0, \widetilde{\mathfrak{p}}_1, \ldots, \widetilde{\mathfrak{p}}_{r-1}, \mathfrak{p}_r)$ we required.

(ii) We are now ready to prove (b) $\implies$ (a) in (ii), which we do by induction on n. The case $n = 1$ is (i) precisely, so we have to perform the induction step for $n \geq 2$: Let $(\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$ be a CPI of R with $\mathfrak{p}_r = \mathfrak{p}$. By assumption $\mathfrak{p}$ is minimal over $\mathfrak{a} = \langle a_1, \ldots, a_n \rangle_{\mathfrak{i}}$. As $a_1 \in \mathfrak{p}$ we may use (iii) to find another CPI $(\mathfrak{p}_0, \widetilde{\mathfrak{p}}_1, \ldots, \widetilde{\mathfrak{p}}_{r-1}, \mathfrak{p}_r)$ of the same length, with $a_1 \in \widetilde{\mathfrak{p}}_1$. Thus, without loss of generality, we may take to this chain and suppose $a_1 \in \mathfrak{p}_1$ already. Now let $\mathfrak{a}_1 := a_1 R$ and for any $k \in 2 \ldots n$ we write $\overline{a}_k := a_k + \mathfrak{a}_1 \in R/\mathfrak{a}_1$. By the correspondence theorem of ideals (1.71) we then find a CPI in $R/\mathfrak{a}_1$ given by

$$\mathfrak{p}_1 \big/ \mathfrak{a}_1 \;\subset\; \ldots \;\subset\; \mathfrak{p}_r \big/ \mathfrak{a}_1 \;=\; \mathfrak{p} \big/ \mathfrak{a}_1$$

As this chain is of length $r-1$ we conclude $r - 1 \leq \operatorname{height}(\mathfrak{p}/\mathfrak{a}_1)$. Let us abbreviate $\overline{\mathfrak{a}} := \mathfrak{a}/\mathfrak{a}_1$ and likewise with any over ideal $\mathfrak{p}_k$. Then we claim, that $\overline{\mathfrak{p}} = \mathfrak{p}/\mathfrak{a}_1$ is minimal over $\overline{\mathfrak{a}}$: Suppose there was some prime ideal in between $\overline{\mathfrak{a}} \subseteq \overline{\mathfrak{p}}' \subseteq \overline{\mathfrak{p}}$ then (by the correspondence theorem of ideals again) $\overline{\mathfrak{p}}'$ would be of the form $\overline{\mathfrak{p}}' = \mathfrak{p}'/\mathfrak{a}_1$ for some $\mathfrak{p}' \in \operatorname{Spec}(R)$ with $\mathfrak{a}_1 \subseteq \mathfrak{p}'$. In particular $a_1 \in \mathfrak{p}'$. And as $\overline{a}_k \in \overline{\mathfrak{a}} \subseteq \overline{\mathfrak{p}}'$ we also get $a_k \in \mathfrak{p}'$ for any $k \in 2 \ldots n$. Together this is $a_k \in \mathfrak{p}'$ for any $k \in 1 \ldots n$ and hence $\mathfrak{a} \subseteq \mathfrak{p}'$. As also $\mathfrak{p}' \subseteq \mathfrak{p}$ by assumption, but $\mathfrak{p}$ is minimal over $\mathfrak{a}$, we conclude $\mathfrak{p}' = \mathfrak{p}$ and hence $\overline{\mathfrak{p}}' = \overline{\mathfrak{p}}$. That is $\overline{\mathfrak{p}}$ truly is minimal over $\overline{\mathfrak{a}}$.

But $R/\mathfrak{a}_1$ is a noetherian ring again and $\overline{\mathfrak{a}} = \langle \overline{a}_2, \ldots, \overline{a}_n \rangle_{\mathfrak{i}}$ is generated by $n-1$ elements (clearly $\overline{a}_1 = 0$ does not contribute). Hence we may use the induction hypothesis for $\overline{\mathfrak{p}}$, which yields the estimate $\operatorname{height}(\overline{\mathfrak{p}}) \leq n-1$. Let us combine the inequalities we found

$$r - 1 \;\leq\; \operatorname{height}(\overline{\mathfrak{p}}) \;\leq\; n - 1$$

That is $r \leq n$. And as we started with an arbitrary CPI ending in $\mathfrak{p}$ there are no CPIs in R of length greater n, that end in $\mathfrak{p}$. And this means $\operatorname{height}(\mathfrak{p}) \leq n$ as claimed.

(iii) Pick up a prime ideal $\mathfrak{p} \in \operatorname{Spec}(R)$ that is minimal over $\mathfrak{a}$, which is possible, according to (2.18). As $\mathfrak{a} \subseteq \mathfrak{p}$, we have $\operatorname{height}(\mathfrak{a}) \leq \operatorname{height}(\mathfrak{p})$. Now pick up some $a_k \in R$ such that $\mathfrak{a} = \langle a_1, \ldots, a_n \rangle_{\mathfrak{i}}$ where $n = \operatorname{rank}(\mathfrak{a})$. Then $\mathfrak{p}$ is a prime ideal, that is minimal over $\langle a_1, \ldots, a_n \rangle_{\mathfrak{i}}$ and thereby $\operatorname{height}(\mathfrak{p}) \leq n$ by the (b) $\implies$ (a) part, of (ii). Together this is

$$\operatorname{height}(\mathfrak{a}) \;\leq\; \operatorname{height}(\mathfrak{p}) \;\leq\; n \;=\; \operatorname{rank}(\mathfrak{a})$$

(iv) **Case 1:** For $n = m$ we only have to consider any prime ideal $\mathfrak{p}_m$ minimal over $\mathfrak{a}_m = \mathfrak{a} = \langle a_1, \ldots, a_m \rangle_{\mathfrak{i}}$. By the (b) $\implies$ (a) part in (ii) we also know $\operatorname{height}(\mathfrak{p}_m) \leq m$. But as $\mathfrak{a} \subseteq \mathfrak{p}_m$ we also have $m = \operatorname{height}(\mathfrak{a}) \leq \operatorname{height}(\mathfrak{p}_m)$. Together this is $\operatorname{height}(\mathfrak{p}_m) = m$ for any prime ideal $\mathfrak{p}_m$ of R, that is minimal over $\mathfrak{a}$.

Case 2: For $n = m + 1$ we argue in the following way: Recall that $\mathbb{V}(\mathfrak{a})_*$ denotes the set of prime

ideals, minimal over $\mathfrak{a}$ and *suppose* we had

$$\mathfrak{b} \;\subseteq\; \bigcup \mathbb{V}(\mathfrak{a})_*$$

As R is a noetherian ring, $\mathbb{V}(\mathfrak{a})_*$ is a finite set, according to (2.45.(iv)). So $\mathfrak{b}$ is contained in a finite union of prime ideals and hence by prime avoidance (2.14.(iii)) it is contained $\mathfrak{b} \subseteq \mathfrak{p}$ in one of those $\mathfrak{p} \in \mathbb{V}(\mathfrak{a})_*$. That is $\mathfrak{p}$ would be a prime ideal, that also is minimal over $\mathfrak{a}$. As $\mathfrak{a} = \langle a_1, \ldots, a_m \rangle_{\mathfrak{i}}$ the (b) $\implies$ (a) part of (ii) yields $\operatorname{height}(\mathfrak{p}) \leq m$. But as $\mathfrak{b} \subseteq \mathfrak{p}$ we have

$$m \;<\; n \;\leq\; \operatorname{height}(\mathfrak{b}) \;\leq\; \operatorname{height}(\mathfrak{p}) \;\leq\; m$$

This contradiction shows $\mathfrak{b} \not\subseteq \mathfrak{p}$ for any prime ideal, minimal over $\mathfrak{a}$ and hence (due to prime avoidance) the above inclusion of $\mathfrak{b}$ is *untrue*. That is there is some $a_n \in R$ such that

$$a_n \;\in\; \mathfrak{b} \setminus \bigcup \mathbb{V}(\mathfrak{a})_*$$

It remains to prove, that any prime ideal $\mathfrak{p}_n$ minimal over $\mathfrak{a}_n$ has $\operatorname{height}(\mathfrak{p}_n) = 0$. Note that $\mathfrak{a}_n = a_1R + \cdots + a_nR = \mathfrak{a} + a_nR$ and therefore $\operatorname{height}(\mathfrak{p}_n) \leq n$ by the (b) $\implies$ (a) part of (ii). Conversely, as we have $\mathfrak{a} \subseteq \mathfrak{a}_n \subseteq \mathfrak{p}_n$ there is some prime ideal $\mathfrak{p}'$ of R, that is minimal over $\mathfrak{a}$, by (2.18.(iv)). By construction this means $a_n \notin \mathfrak{p}'$. But as $a_n \in \mathfrak{a}_n \subseteq \mathfrak{p}_n$ we have $a_n \in \mathfrak{p}_n \setminus \mathfrak{p}'$. In particular we have a strict inclusion $\mathfrak{p}' \subset \mathfrak{p}_n$ and thereby $\operatorname{height}(\mathfrak{p}') < \operatorname{height}(\mathfrak{p}_n)$ by (vi). But by case 1 we know $\operatorname{height}(\mathfrak{p}') = m$ such that we conclude $\operatorname{height}(\mathfrak{p}_n) = m+1 = n$ from

$$m \;=\; \operatorname{height}(\mathfrak{p}') \;<\; \operatorname{height}(\mathfrak{p}_n) \;\leq\; n \;=\; m+1$$

Case 3: For $n \geq m+2$ we use induction on $n-m$. We have dealt with $n-m=0$ in case 1 and case 2 was the foundation of the induction, as $n-m=1$. Then we continue and have $\operatorname{height}(\mathfrak{p}_{n-1}) = n-1$ for any prime ideal $\mathfrak{p}_{n-1}$ that is minimal over $\mathfrak{a}_{n-1}$. In particular $\operatorname{height}(\mathfrak{a}_{n-1}) = n-1$ by (8.69.(viii)). Then by case 2 again we conclude, that there is some $a_n \in \mathfrak{b}$ such that $\operatorname{height}(\mathfrak{p}_n) = n$ for any prime ideal $\mathfrak{p}_n$ that is minimal over $\mathfrak{a}_n$. And this had to be proved.

(ii) Now we are ready for (a) $\implies$ (b): Let $r := \operatorname{height}(\mathfrak{p}) \leq n$ and use (iv) with the following parameters: $m = 0$, $n = r$, $\mathfrak{a} = 0$ and $\mathfrak{b} = \mathfrak{p}$. Then there are some $a_1, \ldots, a_r \in \mathfrak{p}$, such that for any prime ideal $\mathfrak{p}'$ of R, that is minimal over $\mathfrak{a}_r = \langle a_1, \ldots, a_r \rangle_{\mathfrak{i}}$ we have $\operatorname{height}(\mathfrak{p}') = r$. By construction we have $\mathfrak{a}_r \subseteq \mathfrak{p}$, now suppose $\mathfrak{p}$ was not minimal over $\mathfrak{a}_r$. Then there would be some prime ideal $\mathfrak{p}'$ with $\mathfrak{a}_r \subseteq \mathfrak{p}' \subseteq \mathfrak{p}$, that is minimal over $\mathfrak{a}_r$. In particular $\operatorname{height}(\mathfrak{p}') = r$. Once again (vi) would turn $\mathfrak{p}' \subseteq \mathfrak{p}$ into $r = \operatorname{height}(\mathfrak{p}') < \operatorname{height}(\mathfrak{p}) = r$, from which we conclude $\mathfrak{p}' = \mathfrak{p}$. That is $\mathfrak{p}$ is minimal over $\mathfrak{a}_r$ such that we have found the elements $a_1, \ldots, a_r$. If the n in (ii) exceeds r, just fill up $a_{r+1} = \cdots = a_n = 0 \in \mathfrak{p}$, then $\langle a_1, \ldots, a_n \rangle_{\mathfrak{i}} = \mathfrak{a}_r$ is unchanged and hence $\mathfrak{p}$ is minimal over $\langle a_1, \ldots, a_n \rangle_{\mathfrak{i}}$ too.

(vi) Clearly we use induction on r: For $r = 0$ we have $\mathfrak{a}_0 = 0$ such that $\operatorname{height}(\mathfrak{a}_0) = 0$ is granted. Also, as we started with a CPI $\mathfrak{p}_0$ is a minimal ideal and hence $\mathfrak{p}_0$ is minimal over $\mathfrak{a}_0$.

For the induction step, we use (v) with the following parameters: $m = r-1$, $n = r$, $\mathfrak{a} := \mathfrak{a}_{r-1}$ and $\mathfrak{b} := \mathfrak{p}_r$. Then by (v) there is some $a_r \in \mathfrak{p}_r$ such that for any prime ideal $\mathfrak{p}'$ minimal over $\mathfrak{a}_r$ he

have height$(\mathfrak{p}') = r$. In particular we already have height$(\mathfrak{a}_r) = r$. And as $\mathfrak{a}_{r-1} \subseteq \mathfrak{p}_{r-1} \subseteq \mathfrak{p}_r$ and $a_r \in \mathfrak{p}_r$ we have $\mathfrak{a}_r \subseteq \mathfrak{p}_r$ by construction. It remains to prove, that $\mathfrak{p}_r$ is minimal over $\mathfrak{a}_r$. So suppose it was not, then there was some $\mathfrak{p}'$ with $\mathfrak{a}_r \subseteq \mathfrak{p}' \subset \mathfrak{p}_r$. In particular height$(\mathfrak{p}') <$ height$(\mathfrak{p}_r)$. As $\mathfrak{a}_r \subseteq \mathfrak{p}'$ we have $r =$ height$(\mathfrak{a}_r) \leq$ height$(\mathfrak{p}') <$ height$(\mathfrak{p}_r) = r$. From this contradiction, we find that there is no such $\mathfrak{p}'$ and hence $\mathfrak{p}_r$ is minimal over $\mathfrak{a}_r$, as claimed.

(vii) Suppose we had height$(\mathfrak{p}) = 0$, then $\mathfrak{p}$ would be a minimal prime and as such $\mathfrak{p} \subseteq \text{ZD}(R)$, by (2.19.(ii)). But as $a \in \text{NZD}(R)$ and $a \in \mathfrak{p}$ this is untrue, such that height$(\mathfrak{p}) \geq 1$. Also, as R is a noetherian ring, $\mathfrak{p}$ is of finite height, by (ii), such that (8.69.(xii)) already tells us height$(\mathfrak{p}/aR) <$ height$(\mathfrak{p})$. In other words that is the inequality

$$\text{height}\left(\mathfrak{p}\,\middle/_{aR}\right) \;\leq\; \text{height}(\mathfrak{p}) - 1$$

Also, as $\mathfrak{p}$ is of finite height, we may pick up a CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$ in R such that $\mathfrak{p}_r = \mathfrak{p}$ and $r =$ height$(\mathfrak{p})$. And as we also have (iv) there is another CPI $(\mathfrak{p}_0, \widetilde{\mathfrak{p}}_1, \ldots, \widetilde{\mathfrak{p}}_{r-1}, \mathfrak{p}_r)$ such that $a \in \widetilde{\mathfrak{p}}_1$. Then we find a CPI in R/aR of length $r-1$

$$\widetilde{\mathfrak{p}}_1\,\big/_{aR} \;\subset\; \ldots \;\subset\; \widetilde{\mathfrak{p}}_{r-1}\,\big/_{aR} \;\subset\; \mathfrak{p}\,\big/_{aR}$$

ending in $\mathfrak{p}/aR$. In particular height$(\mathfrak{p}/aR) \geq r - 1 =$ height$(\mathfrak{p}) - 1$. Thus we have found the converse inequality, too and hence the equality of the two terms.

□

Proof of (8.82):

(2) As xz and $yz \in zR$ we have $\mathfrak{a} \subseteq zR$. And as $\mathfrak{a} \subseteq zR \subset yR + zR \subset xR + yR + zR$ is a CPI in R the correspondence theorem tells us, that $\overline{z}A \subset \overline{y}A + \overline{z} \subset \overline{x}A + \overline{y}A + \overline{z}A$ is a CPI of A. In particular we have kdim$(A) \geq 2$. Conversely suppose we had kdim$(A) \geq 3$, then there was some CPI $(\mathfrak{q}_0, \ldots, \mathfrak{q}_3)$ of length 3 inside A and therefore height$(\mathfrak{q}_3) \geq 3$. But by the correspondence theorem $\mathfrak{q}_3$ is of the form $\mathfrak{q}_3 = \mathfrak{p}_3/\mathfrak{a}$ for some $\mathfrak{p}_3 \in \text{Spec}(R)$. In particular we have height$(\mathfrak{p}_3) \leq 3$ and as $xz \in \mathfrak{a}$ is a non-zero-divisor we have $3 \leq$ height$(\mathfrak{q}_3) \leq$ height$(\mathfrak{p}_3) - 1 \leq 2$. From this contradiction we get kdim$(A) \leq 2$ and hence kdim$(A) = 2$.

(1) For (1) suppose $\mathfrak{a} \subseteq \mathfrak{p} \subseteq zR$, then $xz \in \mathfrak{p}$ such that $x \in \mathfrak{p}$ or $z \in \mathfrak{p}$. As $x \in zR$ is untrue, we find $z \in \mathfrak{p}$ and thereby $zR \subseteq \mathfrak{p}$ which turns into $\mathfrak{p} = zR$. Thus zR is a minimal prime over $\mathfrak{a}$. Likewise $\mathfrak{a} \subseteq \mathfrak{p} \subseteq xR + yR$ yields xz and $yz \in \mathfrak{p}$ such that $\{x, y\} \subseteq \mathfrak{p}$ or $z \in \mathfrak{p}$. Again $z \in xR + yR$ is untrue such that we have $xR + yR \subseteq \mathfrak{p}$ from which we have $\mathfrak{p} = xR + yR$. Thus $xR + yR$ also is a prime ideal, minimal over $\mathfrak{a}$.

(3) It remains to prove (3): To do this consider any $f \in R = E[x, y, z]$. We split this polynomial into three separate parts

$$\begin{aligned} f &= \sum_{i=0}^{\infty}\sum_{j=0}^{\infty}\sum_{k=0}^{\infty} f[i,j,k]x^i y^j z^k \\ &= \sum_{i=0}^{\infty}\sum_{j=0}^{\infty} f[i,j,0]x^i y^j + \sum_{k=1}^{\infty} f[i,j,k]x^i y^j z^k \end{aligned}$$

$$= \sum_{i=0}^{\infty}\sum_{j=0}^{\infty} f[i,j,0]x^iy^j + \sum_{k=1}^{\infty}\left(f[0,0,k]z^k + \sum_{(i,j)\neq(0,0)} f[i,j,k]x^iy^jz^k \right)$$

Hereby $f(\overline{x},\overline{y},\overline{z}) = f + \mathfrak{a}$ and for any $(i,j) \neq 0$ and $k \geq 1$ we have $x^iy^jz^k + \mathfrak{a} = 0 + \mathfrak{a}$, as both xz and $yz \in \mathfrak{a}$. Thus the residue class of f only retains the terms

$$f(\overline{x},\overline{y},\overline{z}) \;=\; \sum_{i=0}^{\infty}\sum_{j=0}^{\infty} f[i,j,0]\overline{x}^i\overline{y}^j + \sum_{k=1}^{\infty} f[0,0,k]\overline{z}^k$$

Note that this is a basis representation of $\overline{f}$ in the remaining basis of A. In particular if $g \in E[t_1,t_2]$ then $g(\overline{x},\overline{y}) = 0$ implies $g[i,j] = 0$ for and i, $j \in \mathbb{N}$ and therefore $g = 0$. Thus $\overline{x}$ and $\overline{y}$ are algebraically independent. Yet $\overline{z}$ is algebraic over $P := E[\overline{x},\overline{y}]$, as it satisfies the polynomial $\overline{x}t \in P[t]$. As P is an integral domain $P[\overline{z}] : P$ is an algebraic extension, but $P[\overline{z}] = A$ is clear.

(4) By (1) $\overline{\mathfrak{q}} = \langle x,y\rangle_{\mathfrak{i}}/\mathfrak{a} = \overline{x}A + \overline{y}A$ is minimal over $\mathfrak{a}$ such that $\mathrm{height}(\overline{\mathfrak{q}}) = 0$. And in (2) we have found a CPI of length 2 ending in $\overline{\mathfrak{m}} = \langle x,y,z\rangle_{\mathfrak{i}}/\mathfrak{a} = \overline{x}A + \overline{y}A + \overline{x}A$, such that $2 \leq \mathrm{height}(\overline{\mathfrak{m}}) \leq \mathrm{kdim}(A) = 2$. Now for $\overline{\mathfrak{m}}/\overline{\mathfrak{q}}$: If there was some prime ideal in between, by the correspondence theorem, this could have to be of the form $\mathfrak{p}'/\mathfrak{a}$ for some $xR + yR \subset \mathfrak{p}' \subset xR + yR + zR$. But in $R = E[x,y,z]$ it is known from (8.77.(ii)) that $\mathrm{height}(xR + yR + zR) = \mathrm{height}(xR + yR) + 1$. Thus there is no room for such a $\mathfrak{p}'$ and therefore $\mathrm{height}(\overline{\mathfrak{m}}/\overline{\mathfrak{q}}) = 1$, too.

□

Proof of (8.83): (■)

Nota The proof of this example is a little sketchy and we will not prove all the statements of the claim - only enough to complete the counter-example. We feel, that this suffices, as this is an example, not a theorem. It warrants the black-box brand however.

Let us abbreviate $A := E[x,y,z]$. As $E[t]$ is an integral domain, so is the image $\mathrm{im}(\pi) \;\leq_{\mathrm{r}}\; E[t]$ and this implies, that $\mathfrak{p} = \mathrm{kn}(\pi)$ is a prime ideal. Also $\pi(f)(0) = f(0,0,0)$ such that $f \in \mathfrak{p}$ [and hence $\pi(f) = 0$] implies $f \in \mathfrak{m}$. Therefore $\mathfrak{p} \subseteq \mathfrak{m}$, but as $x \in \mathfrak{m}$ yet $x \notin \mathfrak{p}$ we have $\mathfrak{p} \subset \mathfrak{m}$. As E is a field, we have $\mathrm{kdim}(A) = 3$, according to (8.77.(i)) or (8.85.(v)). And as $\mathfrak{p} \subset \mathfrak{m}$ we conclude $\mathrm{height}(\mathfrak{p}) \leq 2$. In fact $\mathrm{height}(\mathfrak{p}) = 2$, but we do not prove this here (■) . Time to introduce the next abbreviation: For $\alpha = (\alpha_1,\alpha_2,\alpha_3) \in \mathbb{N}^3$ let us denote $\omega(\alpha) := 3\alpha_1 + 4\alpha_2 + 5\alpha_3$. Then for any $f \in A$ it is clear, that

$$\pi(f) \;=\; f(t^3,t^4,t^5) \;=\; \sum_{\alpha\in\mathbb{N}^3} f[\alpha]\, t^{\omega(\alpha)} \;=\; \sum_{k=0}^{\infty}\left(\sum_{\omega(\alpha)=k} f[\alpha] \right) t^k$$

Let $A_k := \pi^{-1}(Et^k) = \mathrm{Lh}\{\, x^{\alpha_1}y^{\alpha_2}z^{\alpha_3} \mid \omega(\alpha) = k \,\}$ be A_k is the k-homogeneous component of A under the grading $\deg_\omega$. Consider any $f \in A$ and let $f = \sum_k f_k$ where $f_k \in A_k$. This is the decomposition of f into ω-homogeneous components. Then we can write the identity above, in the following form

$$\pi(f) \;=\; \sum_{k=0}^{\infty}\left(\sum_{\omega(\alpha)=k} f[\alpha] \right) t^k \;=\; \sum_{k=0}^{\infty} f_k(1,1,1)\, t^k$$

Thus we have $f \in \mathfrak{p}$ if and only if $\sum_{\omega(\alpha)=k} f[\alpha] = 0$ for any $k \in \mathbb{N}$. In other words, that is $f \in \mathfrak{p}$ is equivalent to $f_k(1,1,1) = 0$ for any $k \in \mathbb{N}$. In particular, if for some $k \in \mathbb{N}$ there is only one $\alpha \in \mathbb{N}^3$

satisfying $\omega(\alpha) = k$, then $f \in \mathfrak{p}$ implies $f[\alpha] = 0$. Let us compile a table of all the monomials in A of ω-degree up to 10:

monomials	ω
$\mathbf{1}$	0
x	3
y	4
z	5
x^2	6
xy	7
xz, y^2	8
yz, x^3	9
x^2y, z^2	10

By checking a list of all $\alpha \in \mathbb{N}^3$ of absolute value $|\alpha| \leq 3$ we see that any other monomial has an ω-degree exceeding 10. And from our table we find, that $\mathfrak{p}$ does not contain any element $f \in A$ of $\deg_\omega(f) \leq 7$. It does contain $f_1 = xz - y^2$, $f_2 = yz - x^3$ and $x^2y - z^2$ however. Note that these are homogeneous polynomials $f_1 \in A_8$, $f_2 \in A_9$ and $f_3 \in A_{10}$. In particular we have $\langle f_1, f_2, f_3 \rangle_i \subseteq \mathfrak{p}$. In fact these ideals even are equal, but we do not prove this here (■) . We settle with pointing out, that

$$\begin{aligned} x^4 - y^3 &= y(xz - y^2) - x(yz - x^3) \\ x^5 - z^3 &= z(x^2 - z^2) - x^2(yz - x^3) \\ y^5 - z^4 &= (x^2y + z^2)(x^2y - z^2) - y^2(x^4 - y^3) \end{aligned}$$

Let us now assume, that $\mathfrak{p}$ was generated by 2 elements $\{ p_1, p_2 \} \subseteq A$. That if we regard $\mathfrak{p}$ as an A-module we have a surjective homomorphism of A-modules

$$A^2 \twoheadrightarrow \mathfrak{p} \,:\, (f_1, f_2) \mapsto f_1 p_1 + f_2 p_2$$

So what happens if we tensor this homomorphism with $A/\mathfrak{m}$ from the right? By (3.146.(ii)) we have an isomorpism of A-modules of the form

$$\mathfrak{p} \otimes {}^{A}\!\Big/_{\mathfrak{m}} \xrightarrow{\sim} {}^{\mathfrak{p}}\!\Big/_{\mathfrak{m}\mathfrak{p}} \,:\, p \otimes (a + \mathfrak{m}) \mapsto ap + \mathfrak{m}\mathfrak{p}$$

Note that $E \xrightarrow{\sim} A/\mathfrak{m} : a \mapsto a + \mathfrak{m}$ is a canonical isomorphism, by construction of $\mathfrak{m}$. Also A^2 is a free A-module, having the basis elements $(1,0)$ and $(0,1)$. Therefore by (3.146.(v)) we find another isomorphism of A-modules, this time

$$E^2 \xrightarrow{\sim} \left({}^{A}\!\Big/_{\mathfrak{m}}\right)^2 \xrightarrow{\sim} A^2 \otimes {}^{A}\!\Big/_{\mathfrak{m}} \,:\, (a,b) \mapsto \begin{pmatrix}1\\0\end{pmatrix} \otimes (a + \mathfrak{m}) + \begin{pmatrix}0\\1\end{pmatrix} \otimes (b + \mathfrak{m})$$

Note that the image of (a,b) under this isomorphism can be written in the form $(a,b) \otimes (1 + \mathfrak{m})$. This is the form we in the next step. As tensoring is right-exact (3.156) it preserves the surjectivity of the homomorphism above, that is we get a surjective homomorphism of the following form

$$A^2 \otimes {}^{A}\!\Big/_{\mathfrak{m}} \twoheadrightarrow \mathfrak{p} \otimes {}^{A}\!\Big/_{\mathfrak{m}} \,:\, (f_1, f_2) \otimes (a + \mathfrak{m}) \mapsto (f_1 p_1 + f_2 p_2) \otimes (a + \mathfrak{m})$$

Note that $(a,b)\otimes(1+\mathfrak{m})$ is mapped to $(ap_1+bp_2)\otimes(1+\mathfrak{m})$ under this epimorphism. Let us now insert both of the isomorphisms we have found above, then this epimorphism turns into the following epimorphism (of A-modules still).

$$E^2 \twoheadrightarrow \mathfrak{p}\Big/_{\mathfrak{m}\mathfrak{p}} : (a,b) \mapsto ap_1+bp_2+\mathfrak{m}\mathfrak{p}$$

That is we would have $\mathfrak{p}=Ep_1+Ep_2+\mathfrak{m}\mathfrak{p}$. But $\mathfrak{m}\mathfrak{p}$ contains elements of ω-degree no less than 11 (at least 3 from x and 8 from any element of $\mathfrak{p}$. Thus for any $f\in\mathfrak{p}$ the coefficients of f and ap_1+bp_2 of ω-degree up to 10 have to agree. In particular this is true for f_1, f_2 and f_3 as these are of ω-degree up to 10. Let $\overline{p}_i$ be the first 10 ω-coefficients of p_i, then we have argued, that

$$\{\, f_1,f_2,f_3 \,\} \quad\subseteq\quad \mathrm{Lh}_E\{\, \overline{p}_1,\overline{p}_2 \,\}$$

But $\{\, f_1,f_2,f_3 \,\}$ is E-linearly independent, so this set cannot be contained in a space of dimension 2 (or less). And this means that $\mathfrak{p}$ cannot have less than 3 generators. □

Nota This example is given as *exercise* 1.11 in the very first chapter in Hartshorne (GTM 52). And note that we did not even give a full prove here. We leave it to the reader to decide whether Hartshorne (a) saw an easy way to do it, that we don't (b) was careless not to check, whether it can be done easily or (c) just didn't mind to demotivate his readers. It is precisely the existence of such exercises that drove this book's author to write this text, as he frowns upon people of the (b) and (c)-kinds.

Proof of (8.85):

(i) The implication (a) $\implies$ (b) is easy: For $\mathfrak{u}=\mathfrak{p}[t]$ we may take $\mathfrak{v}:=\mathfrak{p}[t]+tR[t]$ which is given to be $\mathfrak{v}=\{\, p+tf \mid p\in\mathfrak{p}, f\in R[t]\,\}$. Then $\mathfrak{v}\cap R=\mathfrak{p}=\mathfrak{u}\cap R$ is clear by construction. Also we have $t\in\mathfrak{v}$ but $t\notin\mathfrak{u}=\mathfrak{p}[t]$, as this would mean $1\in\mathfrak{p}$. And finally we know that $R[t]/\mathfrak{v}$ and $R/\mathfrak{p}$ are isomorphic, according to (3.43.(iv)). As $R/\mathfrak{p}$ is an integral domain ($\mathfrak{p}$ is prime), so is $R[t]/\mathfrak{v}$ and this means that $\mathfrak{v}$ is a prime ideal again. Altogether, we have (b).

Conversely for (b) $\implies$ (a) we first note that $\mathfrak{p}[t]=\mathfrak{p}R[t]=(\mathfrak{u}\cap R)R[t]\subseteq\mathfrak{u}$ is generally true, according to (8.15). We now assume the inclusion was strict $\mathfrak{p}[t]\subset\mathfrak{u}$ and deduce a contradiction - then we have proved $\mathfrak{p}[t]=\mathfrak{u}$. So let us assume $\mathfrak{p}[t]\subset\mathfrak{u}\subset\mathfrak{v}$ was a CPI in $R[t]$, then we obtain another CPI in $R[t]/\mathfrak{p}[t]$ by virtue of

$$0 \;=\; \mathfrak{p}[t]\Big/_{\mathfrak{p}[t]} \;\subset\; \mathfrak{u}\Big/_{\mathfrak{p}[t]} \;\subset\; \mathfrak{v}\Big/_{\mathfrak{p}[t]}$$

Let us abbreviate $\overline{R}:=R/\mathfrak{p}$. For any $a\in R$ let us also abbreviate $\overline{a}:=a+\mathfrak{p}\in\overline{R}$ and for any polynomial $f\in R[t]$ denote $\overline{f}:=\sum_k(f[k]+\mathfrak{p})t^k\in\overline{R}[t]$. Note that there is a canonical isomorphism $R[t]/\mathfrak{p}[t]\xrightarrow{\sim}\overline{R}[t]$, given by $f+\mathfrak{p}[t]\mapsto\overline{f}$, due to (3.43.(iii)). We identify these rings under this isomorphism, that is we use it, without explicitly mentioning it. Now let $\overline{U}:=\overline{R}\setminus\{\overline{0}\}$, that is $\overline{E}:=\mathrm{quot}(\overline{R})=\overline{U}^{-1}\overline{R}$. Under this idenfication the ring extension $\overline{R}[t]:\overline{R}$ turns into a ring-extension $R[t]/\mathfrak{p}[t]:\overline{R}$ under the structural homomorphism $\overline{a}\mapsto a\mathbf{1}+\mathfrak{p}[t]$ and we can consider $\overline{U}\subseteq\overline{R}\subseteq\overline{R}[t]$ as a subset of $R[t]/\mathfrak{p}[t]$ in the form of $\overline{U}=\{\, a\mathbf{1}+\mathfrak{p}[t]\mid a\in R\setminus\mathfrak{p}\,\}$. Then it is

easy to see, that

$$\left(\mathfrak{u}\Big/_{\mathfrak{p}[t]}\right)\cap\overline{R} \;=\; \{\,\overline{a}\mid a\mathbf{1}\in\mathfrak{u}\,\} \;=\; \{\,\overline{a}\mid a\in\mathfrak{u}\cap R\,\} \;=\; {}^{\mathfrak{u}\cap R}\Big/_{\mathfrak{p}} \;=\; \{\,\overline{0}\,\}$$

As $0\in\mathfrak{p}$ we have $0\notin R\setminus\mathfrak{p}$ and thereby $\overline{0}\notin\overline{U}$. That is $\mathfrak{u}/\mathfrak{p}[t]\cap\overline{U}=\emptyset$. Likewise $\mathfrak{v}/\mathfrak{p}[t]=(\mathfrak{v}\cap R)/\mathfrak{p}=\{\overline{0}\}$ by assumption (b) on $\mathfrak{v}$ and hence $\mathfrak{v}/\mathfrak{p}[t]\cap\overline{U}=\emptyset$, as well. By (2.129) we find another CPI in $\overline{U}^{-1}(R[t]\mathfrak{p}[t])$, that is given to be

$$\overline{U}^{-1}\left(\mathfrak{p}[t]\Big/_{\mathfrak{p}[t]}\right) \;\subset\; \overline{U}^{-1}\left(\mathfrak{u}\Big/_{\mathfrak{p}[t]}\right) \;\subset\; \overline{U}^{-1}\left(\mathfrak{v}\Big/_{\mathfrak{p}[t]}\right)$$

However, as $R[t]/\mathfrak{p}[t]\;\xrightarrow{\sim}\;\overline{R}[t]$ is an isomorphism we also get an isomorphism of the rings localized in $\overline{U}$, that is $\overline{U}^{-1}(R[t]/\mathfrak{p}[t])\;\xrightarrow{\sim}\;\overline{U}^{-1}(\overline{R}[t])$ under $(f+\mathfrak{p}[t])/\overline{u}\mapsto\overline{f}/\overline{u}$. And as the localisation commutes with polynomial rings (2.132.(i)), we can continue the isomorphies

$$\overline{U}^{-1}\left(R[t]\Big/_{\mathfrak{p}[t]}\right) \;\cong_{\mathrm{r}}\; \overline{U}^{-1}(\overline{R}[t]) \;\cong_{\mathrm{r}}\; (\overline{U}^{-1}\overline{R})[t] \;=\; \overline{E}[t]$$

Yet $\overline{E}$ is a field and hence $\overline{E}[t]$ is a PID, but not a field. That is we have $\operatorname{kdim}(\overline{E}[t])=1$ and therefore there can not be any CPI of length 2 or more. Thus the above chain cannot exist and this is the contradiction, we needed for $\mathfrak{p}[t]=\mathfrak{u}$.

(ii) Let us start with (b) $\implies$ (a), that is we consider any prime ideal $\mathfrak{p}'\in\operatorname{Spec}(R)$ such that $\mathfrak{a}\subseteq\mathfrak{p}'\subseteq\mathfrak{p}$. In particular we have $\mathfrak{a}[t]\subseteq\mathfrak{p}'[t]\subseteq\mathfrak{p}[t]$, but as $\mathfrak{p}[t]$ is minimal over $\mathfrak{a}[t]$ this implies $\mathfrak{p}'[t]=\mathfrak{p}[t]$. And from this again we get $\mathfrak{p}'=\mathfrak{p}'[t]\cap R=\mathfrak{p}[t]\cap R=\mathfrak{p}$. That is $\mathfrak{p}'=\mathfrak{p}$ which is the minimality of $\mathfrak{p}$ over $\mathfrak{a}$.

Conversely, for (a) $\implies$ (a), we start with a prime ideal $\mathfrak{u}'\in\operatorname{Spec}(R[t])$ such that $\mathfrak{a}[t]\subseteq\mathfrak{u}'\subseteq\mathfrak{p}[t]$ and let $\mathfrak{p}':=\mathfrak{u}'\cap R$. We then get $\mathfrak{a}=\mathfrak{a}[t]\cap R\subseteq\mathfrak{u}'\cap R=\mathfrak{p}'$ and $\mathfrak{p}'=\mathfrak{u}'\cap R\subseteq\mathfrak{p}[t]\cap R=\mathfrak{p}$, that is $\mathfrak{a}\subseteq\mathfrak{p}'\subseteq\mathfrak{p}$. By minimality of $\mathfrak{p}$ over $\mathfrak{a}$ we conclude $\mathfrak{p}'=\mathfrak{p}$, in other words $\mathfrak{u}'\cap R=\mathfrak{p}[t]\cap R$. If $\mathfrak{u}'=\mathfrak{p}[t]$ then we have the minimality of $\mathfrak{p}[t]$ over $\mathfrak{a}[t]$ as desired. Suppose we had $\mathfrak{u}'\subset\mathfrak{p}[t]$ then by (i) we would get $\mathfrak{u}'=\mathfrak{p}'[t]=\mathfrak{p}[t]$ again, a contradiction. So must have had $\mathfrak{u}'=\mathfrak{p}[t]$ from the start, which is the minimality of $\mathfrak{p}[t]$ over $\mathfrak{a}[t]$.

(iii) Let $n:=\operatorname{height}(\mathfrak{p})$, in particular we find a CPI $(\mathfrak{p}_0,\ldots,\mathfrak{p}_n)$ is a CPI in R, with $\mathfrak{p}_n=\mathfrak{p}$. Then this turns into a CPI $(\mathfrak{p}_0,[t]\ldots,\mathfrak{p}_n[t])$ in $R[t]$. And from this chain we see $\operatorname{height}(\mathfrak{p})=n\leq\operatorname{height}(\mathfrak{p}[t])$.

Conversely, as $\operatorname{height}(\mathfrak{p})=n$ Krull's height theorem (8.80.(ii)) tells us that $\mathfrak{p}$ is minimal over an ideal $\mathfrak{a}$ generated by n elements $\mathfrak{a}=a_1R+\cdots+a_nR$. Then it is clear, that $\mathfrak{a}[t]=a_1R[t]+\cdots+a_nR[t]$ by (3.40.(ii)). Now by (ii) $\mathfrak{p}[t]$ is minimal over $\mathfrak{a}[t]$. And therefore by Krull's height theorem again, we get $\operatorname{height}(\mathfrak{p}[t])\leq n=\operatorname{height}(\mathfrak{p})$.

(iv) Let us first prove that $\operatorname{kdim}(R)+1\leq\operatorname{kdim}(R[t])$: If $n=\operatorname{kdim}(R)$, then is suffices to construct a CPI of length $n+1$ in $R[t]$ and this can be done, easily: Let $(\mathfrak{p}_0,\ldots,\mathfrak{p}_n)$ be a CPI in R. Then $(\mathfrak{p}_0[t],\ldots,\mathfrak{p}_n[t])$ is a CPI in $R[t]$. Now define

$$\mathfrak{u}_{n+1} \;:=\; \mathfrak{p}_n[t]+tR[t] \;=\; \{\,p+tf\mid p\in\mathfrak{p}_n,f\in R[t]\,\}$$

As we have argued before, in the first part of (i), $\mathfrak{u}_{n+1}$ is a prime ideal of $R[t]$ and $\mathfrak{p}_n[t]\subset\mathfrak{u}_{n+1}$.

Thus $(\mathfrak{p}_0[t], \ldots, \mathfrak{p}_n[t], \mathfrak{u}_{n+1})$ is a CPI of length $n+1$ in $R[t]$ - just what we needed.

Now for the upper bound: Let $(\mathfrak{u}_0, \ldots, \mathfrak{u}_r)$ be any CPI in $R[t]$ and let $\mathfrak{p}_i := \mathfrak{u}_i \cap R \in \operatorname{Spec}(R)$ for any $i \in 0 \ldots r$. Then we clearly have a chain $\mathfrak{p}_0 \subseteq \ldots \subseteq \mathfrak{p}_r$ of prime ideals in R, but the inclusions need not be strict - at this time. So suppose we had $\mathfrak{p}_0 = \mathfrak{p}_1 = \mathfrak{p}_2$, then we can apply (i) to $\mathfrak{u}_0 \subset \mathfrak{u}_1$ as $\mathfrak{u}_0 \cap R = \mathfrak{u}_1 \cap R$ to find $\mathfrak{u}_0 = \mathfrak{p}_0[t]$. Likewise (i) yielded $\mathfrak{u}_1 = \mathfrak{p}_1[t]$ from $\mathfrak{u}_1 \subset \mathfrak{u}_2$ as $\mathfrak{u}_1 \cap R = \mathfrak{u}_2 \cap R$, too. But then we had

$$\mathfrak{u}_0 \;=\; \mathfrak{p}_0[t] \;=\; \mathfrak{p}_1[t] \;=\; \mathfrak{u}_1$$

which is untrue, as we started with a CPI and hence $\mathfrak{u}_0 \subset \mathfrak{u}_1$. In complete analogy this is true for any three consecutive prime ideals $\mathfrak{p}_i \subseteq \mathfrak{p}_{i+1} \subseteq \mathfrak{p}_{i+2}$. That is there may *never* be three consecutive ideals $\mathfrak{p}_i = \mathfrak{p}_{i+1} = \mathfrak{p}_{i+2}$. In other words: At least every other inclusion has to be strict.

Let us regard the case $n = 0$ exemplarily: Assume there was some CPI in $R[t]$ with $r \geq 2$. In particular $\mathfrak{u}_0 \subset \mathfrak{u}_1 \subset \mathfrak{u}_r$. Then we had $\mathfrak{p}_0 \subseteq \mathfrak{p}_1 \subseteq \mathfrak{p}_2$. As these cannot be identical we either have $\mathfrak{p}_0 \subset \mathfrak{p}_1$ or $\mathfrak{p}_1 \subset \mathfrak{p}_2$ (or both). But this would mean a CPI of length 1 in R, which does not exist, as $\operatorname{kdim}(R) = n = 0$. Thus we have $r \leq 1$ and thereby $\operatorname{kdim}(R[t]) = r \leq 1 = 2n+1$.

Generally let i be the number of equalities in the chain $\mathfrak{p}_0 \subseteq \ldots \subseteq \mathfrak{p}_r$. Likewise let j be the number of strict inclusions $\subset$ in this chain, that is $i + j = r$. As at least every other inclusion has to be strict, we have $i \leq (r+1)/2$ and therefore

$$j \;=\; r - i \;\geq\; r - \frac{r+1}{2} \quad\Longrightarrow\quad 2j \;\leq\; 2r - (r+1) \quad\Longrightarrow\quad 2j+1 \;\geq\; r$$

We may take $r = \operatorname{kdim}(R[t])$ by choosing a CPI of maximal length. The length j of the CPI in R is bounded by $j \leq \operatorname{kdim}(R) = n$, however. Then we have found $r \leq 2j+1 \leq 2n+1$, as well.

(v) It suffices to verify this for the polynomial ring $R[t]$ is one variable, the general statement follows immediately, by induction on the number ov varibles.

Let $n := \operatorname{kdim}(R)$, we already know $n+1 \leq \operatorname{kdim}(R[t])$ from (iv) above. It only remains to prove the converse estimate: So pick up a CPI $(\mathfrak{u}_0, \ldots, \mathfrak{u}_r)$ in $R[t]$ with $r = \operatorname{kdim}(R[t])$ and let $\mathfrak{p}_i := \mathfrak{u}_i \cap R$ for any $i \in 1 \ldots r$. Then it is clear that $\mathfrak{p}_0 \subseteq \ldots \subseteq \mathfrak{p}_r$ is a chain of prime ideals, that is not strictly ascending. In fact if we had $\mathfrak{p}_0 \subset \ldots \subset \mathfrak{p}_r$, then we had $n+1 \leq \operatorname{kdim}(R[t]) = r \leq \operatorname{kdim}(R) = n$. Thus there has to be some $k \in 0 \ldots r-1$ such that $\mathfrak{p}_k = \mathfrak{p}_{k+1}$ such that we may take

$$m \;:=\; \max\{\, k \in 0 \ldots r-1 \mid \mathfrak{p}_k = \mathfrak{p}_{k+1} \,\}$$

In particular we have $\mathfrak{p}_m = \mathfrak{p}_{m+1}$, whereas $\mathfrak{u}_m \subset \mathfrak{u}_{m+1}$. Thus we get $\mathfrak{u}_m = \mathfrak{p}_m[t]$ from (i). But then (iii) tells us

$$m \;\leq\; \operatorname{height}(\mathfrak{u}_m) \;=\; \operatorname{height}(\mathfrak{p}_m)$$

That is there is a CPI $(\mathfrak{q}_0, \ldots, \mathfrak{q}_m)$ in R with $\mathfrak{q}_m = \mathfrak{p}_m$. And as m is maximal, we also have $\mathfrak{p}_m = \mathfrak{p}_{m+1} \subset \mathfrak{p}_{m+2} \subset \ldots \subset \mathfrak{p}_r$. Note that $\mathfrak{q}_m = \mathfrak{p}_m = \mathfrak{p}_{m+1} \subset \mathfrak{p}_{m+2}$, such that altogether we can compose the CPI $(\mathfrak{q}_0, \ldots, \mathfrak{q}_m, \mathfrak{p}_{m+2}, \ldots, \mathfrak{p}_r)$ which is of length $r-1$ in R. That is we have $n = \operatorname{kdim}(R) \geq r-1$ and from this we find the claim $\operatorname{kdim}(R[t]) = r \leq n+1$.

□

Proof of (8.84):

- Let $\{ \mathfrak{p}'_i \mid i \in I \}$ be the set of prime ideals $\mathfrak{p}' \in \operatorname{Spec}(R)$ in between $\mathfrak{p} \subset \mathfrak{p}' \subset \mathfrak{q}$. We have to prove, that either $I = \emptyset$ or I is infinite. We will prove this by contradiction, that is we assume $I = 1 \dots n$ for some $1 \leq n \in \mathbb{N}$ and disprove this assumption.

- Let us first consider the case $\mathfrak{p} = 0$ (in particular R is an integral domain). We first prove that $\mathfrak{q}$ is not contained in the union of the $\mathfrak{p}'_i$. Suppose it was

$$\mathfrak{q} \subseteq \bigcup_{i=1}^{n} \mathfrak{p}'_i$$

 then by prime avoidance (2.14.(iii)) we had $\mathfrak{q} \subseteq \mathfrak{p}'_k$ for some $k \in 1 \dots n$ and thereby $\mathfrak{q} = \mathfrak{p}'_k$. But this contradicts $\mathfrak{p}'_k \subset \mathfrak{q}$. Thus there has to be some $u \in \mathfrak{q}$ that is not contained in any of the $\mathfrak{p}'_i$. We can use this to prove that $\mathfrak{q}$ is a minimal prime ideal over uR: Suppose $uR \subseteq \mathfrak{p}' \subseteq \mathfrak{q}$ for some prime ideal $\mathfrak{p}'$. As $u \notin \mathfrak{p}'_i$ for any $i \in 1 \dots n$, $\mathfrak{p}'$ can not be any of these ideals. But these are all ideals strictly in between 0 and $\mathfrak{q}$. As $\mathfrak{p}'$ is not one of those it must be $\mathfrak{p}' = \mathfrak{q}$. And this is the minimality of $\mathfrak{q} \in \mathbb{V}(uR)_*$. Now by (8.80.(i)) we conclude $\operatorname{height}(\mathfrak{q}) \leq 1$. But as $0 \subset \mathfrak{p}'_1 \subset \mathfrak{q}$ we have $\operatorname{height}(\mathfrak{q}) \geq 2$. This contradiction can only be remedied by $I = \emptyset$ (then there is no $\mathfrak{p}'_1$) or infinite I (then we cannot employ prime avoidance).

- Now for general $\mathfrak{p}$: Consider the quotient ring $R/\mathfrak{p}$. Then the prime ideals strictly in between $0 = \mathfrak{p}/\mathfrak{p}$ and $\mathfrak{q}/\mathfrak{p}$ are $\mathfrak{p}'_i/\mathfrak{p}$, by the correspondence theorem of ideals. And by the above, there either are none or infinitely many.

- Let us now prove, that $\operatorname{kdim}(R) \leq 1$ whenever $\operatorname{Spec}(R)$ is finite: Suppose we had $\operatorname{kdim}(R) \geq 2$, then there would be some prime ideals $\mathfrak{p}_0 \subset \mathfrak{p}_1 \subset \mathfrak{p}_2$. In particular

$$\mathfrak{p}_1 \in \{ \mathfrak{p}' \in \operatorname{Spec}(R) \mid \mathfrak{p}_0 \subset \mathfrak{p}' \subset \mathfrak{p}_2 \}$$

 That is the set on the right hand side is non-empty. By the above this would mean it is infinite. But this contradicts $\operatorname{Spec}(R)$ being finite and this contradiction only leaves $\operatorname{kdim}(R) \leq 1$. Hereby $\operatorname{kdim}(R) = 0$ means R is a field, as in this case 0 is a maximal ideal.

□

Proof of (2.164):

- Let us first prove (a) $\implies$ (b): That is we know R_u is a field and want to prove $E = R[1/u]$ for exactly that $u \neq 0$. That is we consider any $a/b \in E$ and need to show that $a/b = f(1/u)$ for some polynomial $f \in R[t]$. As $b \in R$ we can consider $b/1 \in R_u$. As $b \neq 0$ we have $b/1 \neq 0/1$ and as R_u is a field, this means $b/1 \in (R_u)^*$. That is we find some $b' \in R$ and $m \in \mathbb{N}$, such that $b/1 \cdot b'/u^m = 1/1$ and this is $bb' = u^m$. From this we get $abb' = au^m$ which is $a/b = ab'/u^m \in E$. In particular we have $a/b \in R[1/u]$ and as this is true for any $a/b \in E$ we conclude $E \subseteq R[1/u] \subseteq E$ and hence the equality.

- Conversely the implicatio (b) $\implies$ (a) follows easily: By the universal property (2.120) the homomorphism $\kappa : R \to E : a \mapsto a/1$ induces $\overline{\kappa} : R_u \to E : a/u^k \mapsto (a/1) \cdot (u^k/1)^{-1} = a/u^k$. This

clearly is injective, $a/u^j = b/u^k$ has the same meaning in R_u and E and it is surjective by assumption $E = R[1/u]$: If $f \in R[t]$ let $d := \deg(f)$, then $f(1/u) = \sum_k f[k]1/u^k = (\sum_k f[k]u^{d-k})/u^d \in R_u$. Thus $\overline{\kappa}$ is an isomorphism of rings and in particular R_u is a field.

- The implication (b) $\implies$ (c) is trivial: $1/u \in E$ is an element of E, so if $E = R[1/u]$, then E even is generated by a single element. Now to (c) $\implies$ (b): By assumption we have $E = R[x_1, \ldots, x_n]$ for some $x_i \in E$. Say $x_i = a_i/b_i$ for some a_i, $b_i \in R$ with $b_i \neq 0$. Then we take $u := b_1 \ldots b_n$, which is non-zero, as none of the b_i is. For this u we claim $E = R[1/u]$. Regard any $a/b \in E$, by assumption we have $a/b = f(x_1, \ldots, x_n)$ for some polynomial $f \in R[t_1, \ldots, t_n]$. Now let $m := \max\{\, \alpha_k \mid k \in 1 \ldots n, f[\alpha] \neq 0 \,\}$. Then we compute

$$\frac{a}{b} \;=\; f\left(\frac{a_1}{b_1}, \ldots, \frac{a_n}{b_n}\right) \;=\; \sum_{\alpha \in \mathbb{N}^n} f[\alpha]\, \frac{a^\alpha}{b^\alpha} \;=\; \frac{1}{u^{nm}} \sum_{\alpha \in \mathbb{N}^n} f[\alpha]\, a^\alpha \prod_{i=1}^{n} b_i^{m-\alpha_i}$$

 And as the sum right of $1/u^{nm}$ is an element of R, the latter expression is an element of $R[1/u]$ considered as a subset of E. Thus we have $E \subseteq R[1/u] \subseteq E$ again and thereby (b).

□

Proof of (2.167):

(i) As $S \subseteq E$ and E is a field, S is an integral domain. Consider any $f/g \in \mathrm{QUOT}(S)$, that is $f = a/b$ and $g = c/d$ for some a, b, c and $d \in R$ with b, c, $d \neq 0$. Then $f/g = ad/bc \in E$ again, such that $\mathrm{QUOT}(S) = E$ again (to be precise they are canonically isomorphic, but the difference is purely set-theoretic). By assumption $E = R[1/u]$ for some $u \neq 0$. But then $\mathrm{QUOT}(S) = E = R[1/u] \subseteq S[1/u] \subseteq \mathrm{QUOT}(S)$ implies $\mathrm{QUOT}(S) = S[1/u]$ again, such that S is a Goldman domain, as well.

(ii) Let $U := \{\, u^n \mid n \in \mathbb{N} \,\}$. As $u \notin \mathrm{NIL}(R)$ we have $0 \notin U$ and thereby $R_u = U^{-1}R \neq 0$ is not the zero-ring. By (2.18.(v)) we may choose a maximal element of $\{\, \mathfrak{b} \trianglelefteq_{\mathrm{i}} R \mid \mathfrak{b} \subseteq R \setminus U \,\}$. Let $\mathfrak{g}$ be such a maximal element, which is a prime ideal. By the correspondence theorem (2.129) $\mathfrak{g}$ corresponds to a maximal ideal $\mathfrak{g}_u = U^{-1}\mathfrak{g}$ of R_u. Now by (2.132.(ii)) we have the isomorphism

$$\Big(R \Big/ \mathfrak{g}\Big)_{u+\mathfrak{g}} \;\xrightarrow{\sim}\; R_u \Big/ \mathfrak{g}_u \;:\; \frac{a+\mathfrak{g}}{(u+\mathfrak{g})^n} \;\mapsto\; \frac{a}{u^n} + \mathfrak{g}_u$$

 As $\mathfrak{g}_u$ is a maximal ideal of R_u, the quotient $R_u/\mathfrak{g}_u$ is a field, and hence $(R/\mathfrak{g})_{u+\mathfrak{g}}$ is a field, as well. But this is one of the defining properties of a Goldman domain.

(iii) Suppose the polynomial ring $R[t]$ *was* a Goldman domain. As $R[t] \subseteq E[t] \subseteq E(t) = \mathrm{QUOT}(R[t])$ we find that $E[t]$ is an itermediate ring of $E(t) : R[t]$. But by (i) this implies, that $E[t]$ is a Goldman domain, as well. Then $E[t]$ would be a noetherian Goldman domain and therefore had finitely many prime ideals only, by (2.169). But as E is a field, $E[t]$ even has infinitely many maximal ideals, by (2.80) - a contradiction. Thus we have to drop the assumption of $R[t]$ being a Goldman domain.

 Now for the second part: Let $S : R$ be a ring extension and $x \in S$ such that $R[x]$ is a Goldman domain. Then we regard the evaluation epimorphism $\varepsilon : R[t] \twoheadrightarrow R[x] : f \mapsto f(x)$. If this was injective, then it would even be an isomorphism $\varepsilon : R[t] \xrightarrow{\sim} R[x]$. But as $R[x]$ was assumed to be a Goldman domain and $R[t]$ can't be. Thus there can be no isomorphism between $R[t]$ and $R[x]$ and this means ε is not injective. That is there is some $f \in \mathrm{kn}(\varepsilon)$ with $f \neq 0$, in other words f

is an algebraic relation $f(x) = 0$. And as x is algebraic over R, we have $x \in \mathrm{alg}(S : R)$. But by (8.41) the algebraic closure is an R-sub-algebra of S and thereby $R[x] \subseteq \mathrm{alg}(S : R)$. Thus any $y \in R[x]$ is algebraic over R.

(iv) As the equivalence of (a) and (b) has been proved in (2.164.(i)), we start with (b) $\implies$ (c): That is we consider any non-zero prime ideal $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ and need to show $u \in \mathfrak{p}$. Suppose we had $u \notin \mathfrak{p}$, then $\mathfrak{p}$ would correspond to a prime ideal of R_u. But as R_u is a field, the only (prime) ideal of R_u is 0 and this corresponds to $0 \trianglelefteq_{\mathfrak{i}} R$, not to $\mathfrak{p}$. Thus $u \in \mathfrak{p}$. Now to (c) $\implies$ (d): Suppose there was some non-zero ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ such that $u \notin \sqrt{\mathfrak{a}}$. That is $u^n \notin \mathfrak{a}$ for any $n \in \mathbb{N}$ and thereby $\mathfrak{a} \subseteq R \setminus U$ where $U := \{\, u^n \mid n \in \mathbb{N} \,\}$. Thus by (2.18.(v)) there was a maximal element $\mathfrak{p}$ of $\{\, \mathfrak{b} \trianglelefteq_{\mathfrak{i}} R \mid \mathfrak{a} \subseteq \mathfrak{b} \subseteq R \setminus U \,\}$ and this is a prime ideal. Thereby $\mathfrak{p} \neq 0$, as $0 \neq \mathfrak{a} \subseteq \mathfrak{p}$. Thus we have $u \in \mathfrak{p}$ by (c) in contradiction to $\mathfrak{p} \subseteq R \setminus U$. Let us return (d) $\implies$ (a): Consider any $a/b \in E$, as $b \neq 0$ we have $bR \neq 0$ and by (d) therefore $u \in \sqrt{bR}$. That is $u^n \in bR$ for some $n \in \mathbb{N}$, which means $u^n = br$ for some $r \in R$. As $u \neq 0$ we also have $r \neq 0$ and thereby $a/b = ar/br = ar/u^n \in R[1/n]$. As this is true for any $a/b \in E$ we get $E \subseteq R[1/u] \subseteq E$.

(v) If $\mathfrak{g}$ is a Goldman ideal with $\mathfrak{a}$, then $\sqrt{\mathfrak{a}} \subseteq \mathfrak{g}$, as $\mathfrak{g}$ is a prime ideal. From this we get the inclusion from left to right. Conversely suppose there was some u contained in the intersection of the Goldman ideals $\mathfrak{g}$, but not in $\sqrt{\mathfrak{a}}$. That is $u^n \notin \mathfrak{a}$ for any $n \in \mathbb{N}$ and therefore $u + \mathfrak{a} \notin \mathrm{NIL}(R/\mathfrak{a})$. Thus by (ii) there is a Goldman ideal $\overline{\mathfrak{g}}$ of $\overline{R} := R/\mathfrak{a}$ with $\overline{u} := u + \mathfrak{a} \notin \overline{\mathfrak{g}}$ such that $(\overline{R}/\overline{\mathfrak{g}})_{\overline{u}+\overline{\mathfrak{g}}}$ is a field. By the correspondence theorem $\overline{\mathfrak{g}}$ is of the form $\overline{\mathfrak{g}} = \mathfrak{g}/\mathfrak{a}$ for some prime ideal $\mathfrak{g} \trianglelefteq_{\mathfrak{i}} R$, with $\mathfrak{a} \subseteq \mathfrak{g}$. We also have $u \notin \mathfrak{g}$, as $u + \mathfrak{a} \notin \mathfrak{g}/\mathfrak{a}$. Now, by the third isomorphism theorem, we have an isomorphism of the form

$$R \Big/ \mathfrak{g} \xrightarrow{\sim} \overline{R} \Big/ \overline{\mathfrak{g}} \;:\; b + \mathfrak{g} \mapsto (b + \mathfrak{a}) + \overline{\mathfrak{g}}$$

And by (2.119) this induces the following isomorphism of

$$\left(R \Big/ \mathfrak{g}\right)_{u+\mathfrak{g}} \xrightarrow{\sim} \left(\overline{R} \Big/ \overline{\mathfrak{g}}\right)_{\overline{u}+\overline{\mathfrak{g}}} \;:\; \frac{b + \mathfrak{g}}{(u + \mathfrak{g})^n} \mapsto \frac{(b + \mathfrak{a}) + \overline{\mathfrak{g}}}{(\overline{u} + \overline{\mathfrak{g}})^n}$$

By the Goldman ideal $\overline{\mathfrak{g}}$ the ring on the image-side of this isomorphism is a field and hence the ring on the pre-image side is, as well. But this means $R/\mathfrak{g}$ is a Goldman domain and hence $\mathfrak{g}$ is a Goldman ideal of R.

(vi) Let $E := \mathrm{QUOT}(R)$ and $F := \mathrm{QUOT}(S)$ be the respective quotient fields of R and S. If R is a Goldman domain, then there is some $u \in R$ with $u \neq 0$ such that $E = R[1/u]$. We can regard $S[1/u] : R[1/u]$ as a ring extension again, under the scalar multiplication

$$\frac{a}{u^m}\frac{s}{u^n} \;:=\; \frac{as}{u^m u^n}$$

where $a \in R$, $s \in S$ and $m, n \in \mathbb{N}$. Consider any $s/u^n \in S[1/u]$, as $S : R$ is algebraic there is a polynomial $f \in R[t]$ such that $f(s) = 0$. Now take to the polynomial

$$g(t) \;:=\; \sum_{k=0}^{\infty} f[k] u^{kn} t^k \;\in\; R[t]$$

then it is clear that $g(s/u^n) = f(s)/1 = 0$. As this is true for any $s/u^n \in S[1/u]$ we see, that $S[1/u] : R[1/u]$ is algebraic. Yet $R[1/u] = E$ is a field and hence $S[1/u] : E$ is integral, where E is a field. Then by (8.30.(viii)) we conclude that $S[1/u]$ is a field as well and thereby $F = S[1/u]$. But this means S is a Goldman domain, too.

Conversely if S is a Goldman domain, then $F = S[1/v]$ for some $v \in S$ with $v \neq 0$. As F trivially is algebraic over S and S is algebraic over R, by assumption (8.41.(iv)) tells us, that $F : R$ is algebraic, too. As S also if finitely generated, there are some $x_1, \ldots, x_n \in S$, such that $S = R[x_1, \ldots, x_n]$. Then $F = S[1/v] = R[x_1, \ldots, x_n, 1/v]$. As F is algebraic over R there are polynomials $f_i \in R[t]$ such that $f_i(x_i) = 0$ for any $i \in 1 \ldots n$. Likewise there is some $g \in R[t]$ with $g(1/v) = 0$. Let $a_i \in R$ be the leading coefficient of f_i and $b \in R$ be the leading coefficient of g. Then let

$$R_1 \;:=\; R\left[\frac{1}{a_1}, \ldots, \frac{1}{a_n}, \frac{1}{b}\right] \;\subseteq\; E$$

Then $(1/a_i)f_i \in R_1[t]$ is a monic polynomial over R_1 that satisfies $(1/a_i)f_i(x_i) = 0$. Likewise $(1/b)g \in R_1[t]$ satisfies $g(1/v) = 0$. That is F is generated by elements that are integral over R_1 and hence $F : R_1$ is integral. As $R_1 \subseteq E$ and E is a field F is torsion free, as an R_1-module. Thus by (8.30.(viii)) R_1 is a field. Now $R \subseteq R_1 \subseteq E = \mathrm{quot}(R)$ implies $R_1 = E$. That is E is finitely generated, as an R-algebra and hence R is a Goldman domain.

□

Proof of (2.169):

- First assume that R is a (not necessarily noetherian) integral domain such that $\mathrm{Spec}(R)$ is finite. Let $\mathfrak{p}_i$ (where $i \in 1 \ldots n$) be the collection of non-zero prime ideals of R. For any $i \in 1 \ldots n$ we may choose some $u_i \in \mathfrak{p}_i$ with u_i. Then $u := u_1 \ldots u_n \neq 0$, as well, as R is an integral domain. And thereby we have

$$u \;\in\; \bigcap \{\, \mathfrak{p}_1, \ldots, \mathfrak{p}_n \,\} \;=\; \bigcap \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{p} \neq 0 \,\}$$

 Thus by (2.167.(iii)) we find that R_u is a field and thereby R is a Goldman domain, by definition.

- Conversely suppose R is a noetherian Goldberg domain, then we are going to prove that $\mathrm{Spec}(R)$ is finite. Well, if R is a field, then $\mathrm{Spec}(R) = \{0\}$ and this is a finite set. So we only need to deal with the case where R is not a field. If $E := \mathrm{quot}(R)$, then by assumption we have $E = R[1/u]$ for some $u \neq 0$. By (2.167.(iii)) this means, that $u \in \mathfrak{p}$ for any $\mathfrak{p} \in \mathrm{Spec}(R)$ with $\mathfrak{p} \neq 0$. Let $\mathfrak{a} := uR$ be the ideal generated by u. If we had $\mathfrak{a} = R$, then $1 = uv$ for some $v \in R$ and hence $u \in R^*$. Thus we had $E = R[1/u] = R$, which is R is a field. This has already been dealt with. So we continue with $\mathfrak{a} \neq R$. By (2.45.(iv)) there are finitely many prime ideals, minimal over $\mathfrak{a}$

$$\mathbb{V}(\mathfrak{a})_* \;=\; \{\, \mathfrak{p}_1, \ldots, \mathfrak{p}_m \,\}$$

 So by Krull's principal ideal theorem (8.80.(i)) we get $\mathrm{height}(\mathfrak{p}_i) \leq 1$ for any $i \in 1 \ldots m$. And as $0 \neq u_i \in \mathfrak{p}_i$ we have $0 \subset \mathfrak{p}_i$ such that even $\mathrm{height}(\mathfrak{p}_i) = 1$.

- We continue: Suppose there was some prime ideal $\mathfrak{q} \in \mathrm{Spec}(R)$ such that $\mathfrak{q} \neq 0$ and $\mathfrak{q} \notin \mathbb{V}(\mathfrak{a})_*$. In particular $u \in \mathfrak{q}$ and thereby $\mathfrak{a} \subseteq \mathfrak{q}$. Then due to (2.18.(iv)) there was a prime ideal minimal

over $\mathfrak{a}$, contained in $\mathfrak{q}$. By construction these ideals are the $\mathfrak{p}_i$ such that $0 \subset \mathfrak{a} \subseteq \mathfrak{p}_k \subset \mathfrak{q}$ for some $k \in 1 \ldots m$. The inclusion $\mathfrak{p}_k \subset \mathfrak{q}$ is strict, as $\mathfrak{q}$ is not one of the $\mathfrak{p}_i$. In particular we had $\operatorname{height}(\mathfrak{q}) \geq 2$. Taking $\mathfrak{b} := \mathfrak{q}$ and $n := \operatorname{height}(\mathfrak{b})$ there would be some $a_2, \ldots, a_n \in \mathfrak{q}$ such that $\operatorname{height}(\mathfrak{p}_2) = 2$ for some prime ideal $\mathfrak{p}_2 \trianglelefteq_{\mathfrak{i}} R$ minimal over $uR + a_2R$, according to (8.80.(v)). That is there is some ideal of height 2 containing $\mathfrak{a}$. Let us take this ideal for $\mathfrak{q}$, that is we may assume $\operatorname{height}(\mathfrak{q}) = 2$. Recall that by (8.84) the following set

$$\{\, \mathfrak{p}' \in \operatorname{Spec}(R) \mid 0 \subset \mathfrak{p}' \subset \mathfrak{q} \,\}$$

either is empty or infinite. As $\mathfrak{p}_k$ is contained in this set it is not empty and thereby infinite. In particular there is some $\mathfrak{p}'$ with $0 \subset \mathfrak{p}' \subset \mathfrak{q}$ that is none of the $\mathfrak{p}_i$, the prime ideals minimal over $\mathfrak{a}$. As $\mathfrak{p}' \neq 0$ we have $u \in \mathfrak{p}'$ and therefore $\mathfrak{a} \subseteq \mathfrak{p}'$ again. As before for $\mathfrak{q}$ we use (2.18.(iv)) to find a minimal prime ideal $\mathfrak{p}_j$ in between $\mathfrak{a} \subseteq \mathfrak{p}_j \subset \mathfrak{p}'$. Now we got

$$0 \subset \mathfrak{a} \subseteq \mathfrak{p}_j \subset \mathfrak{p}' \subset \mathfrak{q}$$

Thus we even have $\operatorname{height}(\mathfrak{q}) \geq 3$ in contradiction to $\operatorname{height}(\mathfrak{q}) = 2$. This contradiction can only be remedied if we could not have chosen $\mathfrak{q}$ in the first place. That is 0 and the $\mathfrak{p}_i$ where $i \in 1 \ldots m$ are the only prime ideals of R and this is a finite set.

- We have seen that $\operatorname{height}(\mathfrak{p}_i) = 1$ for any $i \in 1 \ldots n$. And as this are all the prime ideals (apart from 0), that R possesses, we conclude $\operatorname{kdim}(R) = 1$ - or R is a field already, in which case we get $\operatorname{kdim}(R) = 0$, as this was our first case.

- Let us begin with the equivalences of 1-dimensional noetherian integral domains: We have already seen (b) $\iff$ (d) above. But this time we also have $\operatorname{Spec}(R) = \operatorname{Smax}(R) \cup \{0\}$, as $\operatorname{kdim}(R) = 1$. Thus the Jacobson radical of R is just

$$\textsc{jac}(R) \;=\; \bigcap \operatorname{Smax}(R) \;=\; \bigcap \{\, \mathfrak{p} \in \operatorname{Spec}(R) \mid \mathfrak{p} \neq 0 \,\}$$

Using (2.171.(i)) with this property we find that R is a Goldman domain, if and and only $\textsc{jac}(R) \neq 0$. Thus we also have (a) $\iff$ (d). Let us now prove (c) $\implies$ (d): Suppose R *was* a Goldman domain, as R also is a Hilbert domain, by assumption, R would be a field, because of (2.171.(ii)). But a field has $\operatorname{kdim}(R) = 0$ which is not the case, thus R cannot be a Goldman domain. Conversely for (d) $\implies$ (c): As R is not goldman, $R/0 = R$ is not a Goldman domain and this means $0 \trianglelefteq_{\mathfrak{i}} R$ is not a Goldman ideal. Any other prime ideal of R already is a maximal ideal, as $\operatorname{kdim}(R) = 1$. In particular any Goldman ideal of R is maximal and this means that R is a Hilbert domain.

□

Proof of (2.170):
The correct order of proofs is the following: Statements (i) and (ii) here are independent, but (iii) relies on (2.171) statements (i) to (iii). Thus these proofs have to be dealt with, first. Then again (2.171.(iv)) relies on (iii) here, so it is the capstone. We chose to present the statements ordered by themes, and apologize for the awkward order this inflicts on the proofs.

(i) Consider a Goldman ideal $\overline{\mathfrak{g}} \trianglelefteq_{\mathfrak{i}} \overline{R} := R/\mathfrak{a}$. Then by the correspondence theorem in quotient rings

$\overline{\mathfrak{g}}$ is of the form $\overline{\mathfrak{g}} = \mathfrak{g}/\mathfrak{a}$ for some ideal $\mathfrak{g} \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{a} \subseteq \mathfrak{g}$. As $\overline{\mathfrak{g}}$ is prime, so is $\mathfrak{g}$. The third isomorphism theorem yields

$$\overline{R}\Big/_{\overline{\mathfrak{g}}} \;=\; R/\mathfrak{a}\Big/_{\mathfrak{g}/\mathfrak{a}} \;\cong_{\mathrm{r}}\; R\Big/_{\mathfrak{g}}$$

As $\overline{\mathfrak{g}}$ is a Goldmann ideal, the quotient ring $\overline{R}/\overline{\mathfrak{g}}$ is a Goldman domain and by the above isomorphy this makes $R/\mathfrak{g}$ a Goldman domain. That is $\mathfrak{g}$ is a Goldman ideal, again. As R is a Hilbert ring, $\mathfrak{g}$ is maximal and by correspondence again this means $\overline{\mathfrak{g}}$ is maximal. As $\overline{\mathfrak{g}}$ was an arbitrary Goldman ideal of $R/\mathfrak{a}$ this makes $R/\mathfrak{a}$ a Hilbert ring.

(ii) If $\varphi : S \twoheadrightarrow R$ is an epimorphism of rings, then φ induces an isomorphism $\overline{\varphi} : S/\mathrm{kn}(\varphi) \xrightarrow{\sim} R$ of rings. But we assumed S to be a Hilbert ring and $\mathrm{kn}(\varphi) \trianglelefteq_{\mathrm{i}} R$ is an ideal. Thus $S/\mathrm{kn}(\varphi)$ is a Hilbert ring, by (i), too. And by the isomorphism $\overline{\varphi}$ we conclude, that R is a Hilbert ring, as well.

(iii) We will prove (1) in several steps: **Step 1:** Let $A = R[t]$ be the polynomial ring in one variable over R. We know R is a Hilbert ring and want to prove, that A is a Hilbert ring, too. So pick up any Goldman ideal $\mathfrak{h} \trianglelefteq_{\mathrm{i}} A$ and need to show that $\mathfrak{h}$ is maximal. **Step 1.1:** $\mathfrak{g} := \mathfrak{h} \cap R = 0$: As $\mathfrak{h}$ is a prime ideal, so is $\mathfrak{g}$. So in this case we already know that R is an integral domain. Suppose we had $\mathfrak{h} = 0$, then $R[t]/\mathfrak{h} = R[t]$ but by (2.167.(iii)) $R[t]$ is not a Goldman domain, whereas $R[t]/\mathfrak{h}$ is. Take $u := t + \mathfrak{h} \in R[t]/\mathfrak{h}$, then for any $f \in R[t]$ we get $f(u) = f(t) + \mathfrak{h} = f + \mathfrak{h}$ and therefore $R[u] = R[t]/\mathfrak{h}$. Also, as $\mathfrak{h} \neq 0$, there is some $h \in \mathfrak{h}$ such that $h \neq 0$. So for this h we get $h(u) = h + \mathfrak{h} = 0$, such that u is algebraic over R. Altogether $R[u]$ is algebraic and finitely generated over R and a Goldman domain. By (2.167.(vi)) this implies, that R is a Goldman domain. Yet R also is a Hilbert ring by assumption and using (2.171.(ii)) this implies R to be a field. That is u is integral over R and therefore $R[u] : R$ is an integral extension such that $R[u]$ is an integral domain and R is a field. Then (8.30.(viii)) tells us that $R[u] = R[t]/\mathfrak{h}$ is a field. This finally makes $\mathfrak{h}$ a maximal ideal, which had to be shown. **Step 1.2:** general $\mathfrak{g} := \mathfrak{h} \cap R$: Of course we have to reduce this to the case $\mathfrak{g} = 0$. By (i) we know that $\overline{R} := R/\mathfrak{g}$ is a Hilbert ring again. Now we regard everything inside the polynomial ring $\overline{R}[t]$ using the isomorphism in (3.43.(ii))

$$R\Big/_{\mathfrak{g}} \;\hookrightarrow\; R[t]\Big/_{\mathfrak{g}[t]} \;\cong_{\mathrm{r}}\; \Big(R\Big/_{\mathfrak{g}}\Big)[t]$$

As $\mathfrak{g}[t] = (\mathfrak{h} \cap R)R[t] \subseteq \mathfrak{h}$ we can regard the ideal $\overline{\mathfrak{h}} := \mathfrak{h}/\mathfrak{g}[t]$. And $\mathfrak{g}[t]$ corresponds to the zero-ideal of $\overline{R}[t]$. Also $\overline{R}[t]/\overline{\mathfrak{h}}$ is isomorphic to $R[t]/\mathfrak{h}$ due to the third isomorphism theorem. As $\mathfrak{h}$ is a Goldman ideal, $R[t]/\mathfrak{h}$ is a Goldman domain and hence $\overline{R}[t]/\overline{\mathfrak{h}}$ is a Goldman domain. So by step 1.1 above we conclude that $\overline{\mathfrak{h}}$ is a maximal ideal, but by correspondence, this means $\mathfrak{h}$ is a maximal ideal. As this is true for a general Goldman ideal $\mathfrak{h}$, we conclude that $R[t]$ is a Hilbert ring again. **Step 2:** By induction on n it is clear, that for any $n \in \mathbb{N}$ the polynomial ring $R[t_1, \ldots, t_n]$ is a Hilbert ring again. **Step 3:** If A is finitely generated, say $A = R[x_1, \ldots, x_n]$ for some $x_i \in A$, then we get an epimorphism of R-algebras $R[t_1, \ldots, t_n] \twoheadrightarrow A$ by $f \mapsto f(x_1, \ldots, x_n)$. As R is a Hilbert ring, so is $R[t_1, \ldots, t_n]$ by step 2. But by (ii) the image of a Hilbert ring is a Hilbert ring again, and A is such an image.

(iii) So let us prove properties (2) and (3) next: **Step 1:** $A = R[t_1, \ldots, t_n]$: Let us prove these properties by induction on n. In case $n = 0$ we have $A = R$ and hence $\mathfrak{m} = \mathfrak{n} \cap R = \mathfrak{n}$ is a maximal ideal

and thereby $[R/\mathfrak{n} : R/\mathfrak{m}] = 1$. Now for the induction step we have $B := R[t_1, \ldots, t_{n+1}]$ and let $A := R[t_1, \ldots, t_n]$ and $t := t_{n+1}$ such that $B = A[t]$. Consider any maximal ideal $\mathfrak{n} \trianglelefteq_{\mathrm{i}} B$ and let $\mathfrak{m} := \mathfrak{n} \cap A$. As $\mathfrak{n}$ is maximal (2.171.(iii)) tells us, that $\mathfrak{m}$ is a Goldman ideal. But R is a Hilbert ring, so A is a Hilbert ring, too. Therefore $\mathfrak{m}$ is a maximal ideal again. Thus by (2.168.(i)) $\mathfrak{n}$ is of the form $\mathfrak{n} = \mathfrak{m}[t] + fB$ for some monic polynomial $f \in A[t]$ such that $f + \mathfrak{m}[t]$ is a prime element of $B/\mathfrak{m}[t]$. Let us expand $B/\mathfrak{n}$ using the third isomorphism theorem

$$B\Big/_{\mathfrak{n}} \;=\; B\Big/_{\mathfrak{m}[t]+fB} \;\xrightarrow{\sim}\; A[t]/\mathfrak{m}[t]\Big/_{(\mathfrak{m}[t]+fB)/\mathfrak{m}[t]} \;:\; g+\mathfrak{n} \;\mapsto\; \big(g+\mathfrak{m}[t]\big)+\mathfrak{n}\Big/_{\mathfrak{m}[t]}$$

Then we can use the isomorphism $A[t]/\mathfrak{m}[t] \xrightarrow{\sim} (A/\mathfrak{m})[t]$ given by $g + \mathfrak{m}[t] \mapsto \overline{g} := \sum_k (g[k] + \mathfrak{m})t^k$. The ideal $\mathfrak{n}/\mathfrak{m}[t] = (\mathfrak{m}[t] + fB)/\mathfrak{m}[t]$ is mapped to $\overline{f}\,(A/\mathfrak{m})[t]$ and thereby we can reshape the above isomorphism into the form

$$B\Big/_{\mathfrak{n}} \;\xrightarrow{\sim}\; (A/\mathfrak{m})[t]\Big/_{\langle\overline{f}\rangle_{\mathrm{i}}} \;:\; g+\mathfrak{n} \;\mapsto\; \overline{g}+\mathfrak{n}\Big/_{\mathfrak{m}[t]}$$

Then by (8.10.(i)) $(A/\mathfrak{m})[t]/\langle\overline{f}\rangle_{\mathrm{i}}$ is finitely generated as an $(A/\mathfrak{m})$-vector space, the dimension being given to be $\deg(\overline{f}) = \deg(f)$, as f is monic. That is we have

$$\Big[B\Big/_{\mathfrak{n}} : A\Big/_{\mathfrak{m}}\Big] \;=\; \deg(f) \;<\; \infty$$

Now by induction hypothesis $\mathfrak{q} := \mathfrak{m} \cap R$ is a maximal ideal of R and $A/\mathfrak{m}$ and $A/\mathfrak{m}$ is a finite-dimensional $R/\mathfrak{q}$-vector space. Then we can use the degree formula (8.7.(iv)) to find

$$\Big[B\Big/_{\mathfrak{n}} : R\Big/_{\mathfrak{q}}\Big] \;=\; \Big[B\Big/_{\mathfrak{n}} : A\Big/_{\mathfrak{m}}\Big] \cdot \Big[A\Big/_{\mathfrak{m}} : R\Big/_{\mathfrak{q}}\Big] \;<\; \infty$$

Step 2: general A: By assumption $A = R[x_1, \ldots, x_n]$ is finitely generated and hence A is isomorphic to $R[t_1, \ldots, t_n]/\mathfrak{a}$ where the ideal $\mathfrak{a}$ is the kernel of $f \mapsto f(x_1, \ldots, x_n)$. Consider a maximal ideal $\overline{\mathfrak{n}} \trianglelefteq_{\mathrm{i}} R[t_1, \ldots, t_n]/\mathfrak{a}$, then $\overline{\mathfrak{n}}$ is of the form $\overline{\mathfrak{n}} = \mathfrak{n}/\mathfrak{a}$ for some maximal ideal $\mathfrak{n} \trianglelefteq_{\mathrm{i}} R[t_1, \ldots, t_n]$ with $\mathfrak{a} \subseteq \mathfrak{n}$. As $\mathfrak{n}$ is maximal step 1 yields, that $\mathfrak{m} := \mathfrak{n} \cap R$ is a maximal ideal again and that

$$\Big[R[t_1, \ldots, t_n]\Big/_{\mathfrak{n}} : R\Big/_{\mathfrak{m}}\Big] \;<\; \infty$$

Let us take a look at $\overline{\mathfrak{n}} \cap R$, that is the set of all $a \in R$ such that $a1_A = a(\mathbf{1} + \mathfrak{a}) \in \overline{\mathfrak{n}}$. But this is $a\mathbf{1} + \mathfrak{a} \in \mathfrak{n}/\mathfrak{a}$ which amounts to $a\mathbf{1} \in \mathfrak{n}$. But this is precisely the definition of $a \in \mathfrak{n} \cap R$ and thereby we have found the equality of

$$\overline{\mathfrak{n}} \cap R \;=\; \mathfrak{n} \cap R \;=\; \mathfrak{m}$$

In particular $\overline{\mathfrak{n}} \cap R$ is a maximal ideal of R. And as always the third isomorphism theorem turns $A/\overline{\mathfrak{n}}$ - which is given to be $(R[t_1, \ldots, t_n]/\mathfrak{a})/(\mathfrak{n}/\mathfrak{a})$ - into $R[t_1, \ldots, t_n]/\mathfrak{n}$. As this is an isomorphism of R-algebras, we find that we truly have a finite field extension

$$\Big[A\Big/_{\overline{\mathfrak{n}}} : R\Big/_{\mathfrak{m}}\Big] \;=\; \Big[R[t_1, \ldots, t_n]\Big/_{\mathfrak{n}} : R\Big/_{\mathfrak{m}}\Big] \;<\; \infty$$

□

Proof of (2.171):

(i) The equivalence (a) $\iff$ (b) is purely definitional: $0 \trianglelefteq_{\mathfrak{i}} R$ is a Goldman ideal, if and only if $R/0$ is a Goldman domain. But $R/0 = R$ is the same ring, naturally. For the other equivalences let us abbreviate $\mathcal{P} := \{\, \mathfrak{p} \in \operatorname{Spec}(R) \mid \mathfrak{p} \neq 0 \,\}$ and $E := \operatorname{QUOT}(R)$ be the quotient field of R. The equivalence (a) $\iff$ (c) is easy: If R is goldman, then $E = R[1/u]$ for some $u \in R$ with $u \neq 0$. Thus by (2.167.(iii)) we have $u \in \bigcap \mathcal{P}$ and therefore $\bigcap \mathcal{P} \neq 0$. Conversely if $\bigcap \mathcal{P} \neq 0$ we can choose some $u \in \bigcap \mathcal{P}$ with $u \neq 0$ and find $E = R[1/u]$ by (2.167.(iii)) again.

In (a) $\implies$ (d) R is a Goldman domain. That is $E = R[1/u]$ for some $u \in R$ with $u \neq 0$. Thereby the following homomorphism of R-algebras is surjective

$$\varepsilon \;:\; R[t] \;\twoheadrightarrow\; E \;:\; f \mapsto f\left(\frac{1}{u}\right)$$

Let $\mathfrak{m} := \operatorname{kn}(\varepsilon)$ be the kernel of this homomorphism, then ε induces an isomorphism $R[t]/\mathfrak{m} \xrightarrow{\sim} E$. As E is a field, we conclude that $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} R[t]$ is a maximal ideal. And if $a\mathbf{1} \in \mathfrak{m}$ then $0 = \varepsilon(1/u) = a\mathbf{1}(1/u) = a \cdot 1 = a$, such that $\mathfrak{m} \cap R = 0$.

Conversely for (c) $\implies$ (a) we let $u := t + \mathfrak{m} \in R[t]/\mathfrak{m}$. Then it is clear, that for any polynomial $f \in R[t]$ we get $f(u) = f(t + \mathfrak{m}) = f(t) + \mathfrak{m} = f + \mathfrak{m}$. In particular we have $R[u] = R[t]/\mathfrak{m}$ and $f(u) = 0$ is equivalent, to $f \in \mathfrak{m}$. As $\mathfrak{m}$ is a maximal ideal we have $\mathfrak{m} \neq 0$ - else $R[t]$ would be a field, but $t \in R[t]$ is not a unit. Thus we can choose some $f \in \mathfrak{m}$ with $f \in \mathfrak{m}$. And by the reasoning above, this means $f(u) = 0$. That is (1) $u \in R[t]/\mathfrak{m}$ is algebraic over R. Also, by construction, (2) $R[u]$ is finitely generated over R. As $R[u] = R[t]/\mathfrak{m}$ and $\mathfrak{m}$ is maximal, $R[u]$ is a field and hence (3) $R[u]$ is a Goldman domain. Due to properties (1) to (3) we conclude with (2.167.(v)) that R is a Goldman domain, too.

(ii) If F is a field, then F is a Goldman domain and $\operatorname{JAC}(F) = 0$, as 0 is the one and only maximal ideal of a field. Conversely suppose F is a Goldman domain satisfying $\operatorname{JAC}(F) = 0$. Then we have some $u \in F$ with $u \neq 0$ such that F_u is a field. Let $U := \{\, u^n \mid n \in \mathbb{N} \,\}$, that is $F_u = U^{-1}F$. Now consider any maximal ideal $\mathfrak{m}$ of F. Suppose we had $\mathfrak{m} \neq 0$, then there would be some $a \in \mathfrak{m}$ with $a \neq 0$ and hence $a/1 \in U^{-1}\mathfrak{m}$. But $a/1 \neq 0/1$ as $u \neq 0$ and F is an integral domain, such that $U^{-1}\mathfrak{m} \trianglelefteq_{\mathfrak{i}} F_u$ is non-zero. Yet F_u is a field, so any non-zero ideal has to be full $U^{-1}\mathfrak{m} = F_u$. Therefore $1/1 = m/u^n$ for some $m \in \mathfrak{m}$ which is $u^n \in \mathfrak{m}$. As $\mathfrak{m}$ is a prime ideal we conclude $n \neq 0$ and $u \in \mathfrak{m}$. Now, as $\mathfrak{m}$ has been an arbitrary maximal ideal of F, we have found $u \in \operatorname{JAC}(F)$ which equals 0 by assumption. Thus we have $u = 0$ in contradiction to $u \neq 0$ above. Thus the only maximal ideal of F is $\mathfrak{m} = 0$ and this means that F is a field.

- If F is a field, then F is a Goldman domain and the only prime ideal of F is 0. This is a Goldman ideal, but it also is maximal, hence F also is a Hilbert ring. Conversely suppose F is a Goldman domain and Hilbert ring. As R is an integral domain, $0 \trianglelefteq_{\mathfrak{i}} R$ is a prime ideal. And because of $R/0 = R$ we find that $R/0$ is a Goldman domain. This means 0 is a Goldman ideal and as R is a Hilbert ring, this means that 0 is maximal. But this is the case if and only if R is a field.

(iii) Property (b) is just a reformulation of (c) in (i) for the ring $R/\mathfrak{p}$: By the correspondence theorem of ideals in quotients (1.71) the prime ideals $\overline{\mathfrak{q}}$ of $\overline{R} := R/\mathfrak{p}$ are of the form $\overline{\mathfrak{q}} = \mathfrak{q}/\mathfrak{p}$ for some prime

ideal $\mathfrak{q} \trianglelefteq_{\mathrm{i}} R$ such that $\mathfrak{p} \subseteq \mathfrak{q}$. Thereby $\overline{\mathfrak{q}} \neq 0$ translates into $\mathfrak{p} \subset \mathfrak{q}$. Thus we get

$$\bigcap \{\, \overline{\mathfrak{q}} \in \operatorname{Spec}(\overline{R}) \mid \overline{\mathfrak{q}} \neq 0 \,\} \;=\; {\mathfrak{a}}\big/{\mathfrak{p}} \quad \text{for} \quad \mathfrak{a} := \bigcap \{\, \mathfrak{q} \in \operatorname{Spec}(R) \mid \mathfrak{p} \subset \mathfrak{q} \,\}$$

By (i) $\overline{R}$ is a Goldman domain, if and only if there is some $\overline{u} \in \mathfrak{a}/\mathfrak{p}$ with $\overline{u} \neq 0$. For $\overline{u} = u + \mathfrak{p}$ this translates into $u \in \mathfrak{a}$ with $u \notin \mathfrak{p}$. Thus $R/\mathfrak{p}$ is goldman, iff there is some $u \in \mathfrak{a} \setminus \mathfrak{p}$ and this is the equivalence of (a) and (b). In the next step we will prove the equivalence of (a) and (c):

- By (i) $\overline{R} := R/\mathfrak{p}$ is a Goldman domain if and only if there is some maximal ideal $\overline{\mathfrak{m}} \trianglelefteq_{\mathrm{i}} \overline{R}[t]$ such that $\overline{\mathfrak{m}} \cap \overline{R} = 0$. Using the isomorphism in (3.43.(ii)) we transfer $\overline{\mathfrak{m}}$ to a maximal ideal of $R[t]/\mathfrak{p}[t]$

$$\Phi \;:\; {R[t]}\big/{\mathfrak{p}[t]} \;\xrightarrow{\sim}\; \overline{R}[t] \;:\; f + \mathfrak{p}[t] \;\mapsto\; \sum_{k=0}^{\infty} \big(f[k] + \mathfrak{p}\big)\, t^k$$

That is we let $\mathfrak{m}/\mathfrak{p}[t] := \Phi^{-1}(\overline{\mathfrak{m}})$. Then $\overline{\mathfrak{m}}$ is a maximal ideal of $\overline{R}[t]$ if and only if $\mathfrak{m}$ is a maximal ideal of $R[t]$ - by the correspondence theorem of ideals, applied to $R[t]/\mathfrak{p}[t]$. Let us also verify that for this ideal we get

$$a \in \mathfrak{m} \cap R \quad\Longleftrightarrow\quad a + \mathfrak{p} \in \overline{\mathfrak{m}} \cap \overline{R}$$

By definition $a \in \mathfrak{m} \cap R$ is $a\mathbf{1} \in \mathfrak{m}$ and this of course is $a\mathbf{1} + \mathfrak{p}[t] \in \mathfrak{m}/\mathfrak{p}[t]$. As Φ is an isomorphism this again is $(a + \mathfrak{p})\mathbf{1} = \Phi(a\mathbf{1} + \mathfrak{p}[t]) \in \overline{\mathfrak{m}}$. Using the definition of the retraction again, this is $a + \mathfrak{p} \in \overline{\mathfrak{m}} \cap \overline{R}$. Starting with (a) there is such a maximal ideal $\overline{\mathfrak{m}}$ satisfying $\overline{\mathfrak{m}} \cap \overline{R} = 0$. And the construction above yields a maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R[t]$ for which $a \in \mathfrak{m} \cap R$ is equivalent to $a + \mathfrak{p} \in \overline{\mathfrak{m}} \cap \overline{R} = 0 = \mathfrak{p}/\mathfrak{p}$. The latter is $a \in \mathfrak{p}$ and thereby $\mathfrak{m} \cap R = \mathfrak{p}$. Conversely, if we start with some maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R[t]$ satisfying $\mathfrak{m} \cap R = \mathfrak{p}$ we have $\mathfrak{p}[t] = \mathfrak{p}R[t] = (\mathfrak{m} \cap R)R[t] \subseteq \mathfrak{m}$ and thereby can define $\overline{\mathfrak{m}} := \Phi(\mathfrak{m}/\mathfrak{p}[t])$. This is a maximal of $\overline{R}[t]$ and by the above we have $a + \mathfrak{p} \in \overline{\mathfrak{m}} \cap \overline{R}$ if and only if $a \in \mathfrak{m} \cap R = \mathfrak{p}$ which again is equivalent to $a + \mathfrak{p} = 0 \in \overline{R}$. Thus we have $\overline{\mathfrak{m}} \cap \overline{R} = 0$ and this makes $\overline{R} = R/\mathfrak{p}$ a Goldman domain.

(iv) Let us begin with (a) $\Longrightarrow$ (b): Given any prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ we let $\mathfrak{a} := \bigcap \{\, \mathfrak{m} \in \operatorname{Smax}(R) \mid \mathfrak{p} \subseteq \mathfrak{m} \,\}$. Then $\mathfrak{p} \subseteq \mathfrak{a}$ is clear and we have to show, that even $\mathfrak{p} = \mathfrak{a}$. So suppose we had $u \in \mathfrak{a} \setminus \mathfrak{p}$ and let $U := \{\, u^n \mid n \in \mathbb{N} \,\}$. Then $\mathfrak{p} \cap U = \emptyset$ (as $\mathfrak{p}$ is prime) and hence we could choose a maximal element $\mathfrak{q}$ of $\{\, \mathfrak{b} \trianglelefteq_{\mathrm{i}} R \mid \mathfrak{p} \subseteq \mathfrak{b} \subseteq R \setminus U \,\}$ and by (2.18.(v)) $\mathfrak{q}$ is a prime ideal. Suppose $\mathfrak{q}$ was maximal, as $\mathfrak{p} \subseteq \mathfrak{q}$ and $u \in \mathfrak{a}$ this would imply $u \in \mathfrak{q}$, which is false. Hence $\mathfrak{q}$ is *not* a maximal ideal of R. However $\mathfrak{q}R_u$ is a maximal ideal of R_u by construction. Thus $R_u/\mathfrak{q}R_u$ is a field. But we have the following isomorphism

$$R_u \Big/ \mathfrak{q}R_u \;\xrightarrow{\sim}\; \Big(R \Big/ \mathfrak{q}\Big)_{u+\mathfrak{q}} \;:\; \frac{a}{u^n} + \mathfrak{q}R_u \;\mapsto\; \frac{a + \mathfrak{q}}{u^n + \mathfrak{q}}$$

according to (2.132.(ii)). But then, as $R_u/\mathfrak{q}R_u$ is a field, so is $(R/\mathfrak{q})_{u+\mathfrak{q}}$. But this means $\mathfrak{q}$ is a Goldman ideal of R and as $\mathfrak{q}$ is not maximal, R is not a Hilbert ring. Thus our assumption $u \notin \mathfrak{a} \setminus \mathfrak{p}$ had to be false and this means $\mathfrak{p} = \mathfrak{a}$, which is property (c) of Jacobson rings.

- Conversely for (b) $\Longrightarrow$ (a): If $\mathfrak{g} \trianglelefteq_{\mathrm{i}} R$ is a Goldman ideal, then by definition $R/\mathfrak{g}$ is a Goldman domain. But as R is jacobson by assumption, so is its quotient $R/\mathfrak{g}$, by (2.172.(i)). Now by (ii) together this implies $R/\mathfrak{g}$ to be a field, which in turn means, that $\mathfrak{g}$ is a maximal ideal. And as this

is true for any Goldman ideal, R is a Hilbert ring.

- The implication (a) $\implies$ (c) has already been done in property (2) of (2.170.(iii)). And (a) $\implies$ (d) is not far away either: If A is a finitely generated R-algebra it is isomorphic to a quotient of the polynomial ring $R[t_1,\ldots,t_n]/\mathfrak{n}$. And as A is assumed to be a field $\mathfrak{n} \trianglelefteq_{\mathrm{i}} R[t_1,\ldots,t_n]$ is a maximal ideal. So without loss of generality we may assume $A = R[t_1,\ldots,t_n]/\mathfrak{n}$. Let $\mathfrak{m} := \mathfrak{n} \cap R$, then $\mathfrak{m}$ is a maximal ideal, by property (2) of (2.170.(iii)). And by property (3) there A is a finite extension field of $R/\mathfrak{m}$. That is there is a finite $R/\mathfrak{m}$-basis $\{ x_1,\ldots,x_m \}$ of A (where $x_i = g_i + \mathfrak{n}$ for some $g_i \in R[t_1,\ldots,t_n]$) which means that any $f + \mathfrak{n} \in A$ can be expressed as a $R/\mathfrak{m}$-linear combination

$$f + \mathfrak{n} \;=\; \sum_{i=1}^{n} (a_i + \mathfrak{m})(g_i + \mathfrak{n}) \;=\; \sum_{i=1}^{n} a_i g_i + \mathfrak{n} \;=\; \sum_{i=1}^{n} a_i (g_i + \mathfrak{n})$$

 Thus the $R/\mathfrak{m}$-linear combination already is an R-linear combination and from this we find that the set $\{ x_1,\ldots,x_m \}$ also generates A as an R-module, so A is a finitely generated R-module.

- The implication (c) $\implies$ (a) is straightforward: Consider any Goldman ideal $\mathfrak{p}$ of R. By (iii) there is some maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R[t]$ such that $\mathfrak{p} = \mathfrak{m} \cap R$. But by assumption (c) this implies that $\mathfrak{m} \cap R = \mathfrak{p}$ is maximal. As any Goldman ideal is maximal, R is a Hilbert ring.

- If remains to verify (d) $\implies$ (a), that is we have to verify that every Goldman ideal is maximal. Let us start with a Goldman ideal $\mathfrak{p}$, by (iii) this means there is some $u \in \mathfrak{a} \setminus \mathfrak{p}$ where $\mathfrak{a} := \bigcap \{ \mathfrak{q} \in \operatorname{Spec}(R) \mid \mathfrak{p} \subset \mathfrak{q} \}$. Let $x := u + \mathfrak{p}$ and $\overline{R} := R/\mathfrak{p}$ and distinguish two cases: **Case 1:** $\overline{R}_x$ is a field: As $\overline{R}_x = \overline{R}[1/x]$ is finitely generated over $\overline{R}$ it also is finitely generated over R by the same generating set $\{ 1/u \}$ - as before in (a) $\implies$ (c). By assumption (c), as $\overline{R}_x$ is a field, $\overline{R}_x : R$ is a finite ring extension and thereby integral - by (8.30.(v)). In turn this means that $\overline{R}_x : \overline{R}$ is an integral ring extension. But as $\overline{R}_x$ is a field and $\overline{R}$ is an integral domain this makes $\overline{R}$ a field, according to (8.30.(viii)). But this is the property desired: $\mathfrak{p}$ is a maximal ideal. **Case 2:** $\overline{R}_x$ is not a field: Then there is a maximal ideal $\overline{\mathfrak{n}} \trianglelefteq_{\mathrm{i}} \overline{R}_x$ that satisfies $\overline{\mathfrak{n}} \neq 0$. By the correspondence theorem of ideals in localisations (2.129) $\overline{\mathfrak{n}}$ corresponds to an ideal $\overline{\mathfrak{q}}$ in $\overline{R}$ maximal with the property $x \notin \overline{\mathfrak{q}}$. As $0 \trianglelefteq_{\mathrm{i}} \overline{R}_x$ corresponds to $0 \trianglelefteq_{\mathrm{i}} \overline{R}$ but $\overline{\mathfrak{n}} \neq 0$ we get $\overline{\mathfrak{q}} \neq 0$. And by (2.18.(v)) this $\overline{\mathfrak{q}}$ is prime. As before it is of the form $\overline{\mathfrak{q}} = \mathfrak{q}/\mathfrak{p}$ for some prime ideal $\mathfrak{q} \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{p} \subseteq \mathfrak{q}$. Hereby $\overline{\mathfrak{q}} \neq 0$ turns into $\mathfrak{p} \subset \mathfrak{q}$. And $x \notin \overline{\mathfrak{q}}$ turns into $u \notin \mathfrak{q}$. Altogether we have $\mathfrak{p} \subset \mathfrak{q} \in \operatorname{Spec}(R)$ and therefore $\mathfrak{a} \subseteq \mathfrak{q}$. But $u \in \mathfrak{a}$ such that $u \in \mathfrak{q}$ is a contradiction. Thus case 1 is the only one elegible, case 2 is void and we have proved that $\mathfrak{p}$ is maximal in case 1. So every Goldman ideal is maximal, which is the property of a Hilbert ring.

□

Proof of (2.172):

(ii) Suppose $(T,+,\cdot)$ is another integral domain and $\psi : S \twoheadrightarrow T$ a surjective homomorphism of rings. Then ψ can be composed with $\psi\varphi : R \twoheadrightarrow T$. As R is jacobson we get $\operatorname{JAC}(T) = 0$, by property (f) in the definition (2.33). As this is true for any ψ the same property implies S to be jacobson.

(i) Is an immediate consequence of (ii): It suffices to regard the canonical epimorphism $\varrho : R \twoheadrightarrow R/\mathfrak{a}$ given by $\varrho(a) := a + \mathfrak{a}$. As this is surjective and R is jacobson, so is $R/\mathfrak{a}$, according to (ii).

(vi) Let us denote $U := \{1, u, u^2, \dots\}$ that is $R_u = U^{-1}R$. By the correspondence theorem of ideals in localisations (2.129) there is a one-to-one correspondence of the maximal ideals, given by

$$\begin{array}{rcl} \mathrm{Smax}(R_u) & \longleftrightarrow & \{\, \mathfrak{a} \trianglelefteq_{\mathrm{i}} R \mid \mathfrak{a} \cap U = \emptyset \,\}^* \\ \mathfrak{n} & \mapsto & \mathfrak{n} \cap R \\ \mathfrak{a} R_u & \hookleftarrow & \mathfrak{a} \end{array}$$

If $\mathfrak{m}$ is a maximal ideal with $u \notin \mathfrak{m}$, then $\mathfrak{m}$ already is a maximal element among the $\mathfrak{a}$ with $\mathfrak{a} \cap U = \emptyset$: First of all $1 \notin \mathfrak{m}$, as $\mathfrak{m}$ is proper. Maximal ideals are prime and hence $u^n \in \mathfrak{m}$ would imply $u \in \mathfrak{m}$, which is not. Hence we have $\mathfrak{m} \cap U = \emptyset$. If now $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{a} \cap U = \emptyset$ and $\mathfrak{m} \subseteq \mathfrak{a}$, then $\mathfrak{a}$ is proper, as $1 \notin \mathfrak{a}$ and hence $\mathfrak{m} = \mathfrak{a}$, as $\mathfrak{m}$ is a maximal ideal. Thus $\mathfrak{m}$ is a maximal element amongst the $\mathfrak{a}$ and hence we have an injective map

$$\{\, \mathfrak{m} \in \mathrm{Smax}(R) \mid u \notin \mathfrak{m} \,\} \;\hookrightarrow\; \mathrm{Smax}(R_u) \;:\; \mathfrak{m} \mapsto \mathfrak{m} R_u$$

That's it for general rings. For Jacobson rings we are able to prove, that this map also is surjective: Consider any maximal ideal $\mathfrak{n} \trianglelefteq_{\mathrm{i}} R_u$, then by (2.129) there is a *prime* ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{p} \cap U = \emptyset$, such that $\mathfrak{n} = \mathfrak{p}_u$ where $\mathfrak{p}_u := \mathfrak{p} R_u$. As R is jacobson we have

$$\mathfrak{p} \;=\; \bigcap \{\, \mathfrak{m} \in \mathrm{Smax}(R) \mid \mathfrak{p} \subseteq \mathfrak{m} \,\}$$

As $u \notin \mathfrak{p}$ there has to be some maximal ideal $\mathfrak{m}$ with $\mathfrak{p} \subseteq \mathfrak{m}$ but $u \notin \mathfrak{m}$. As before this means $\mathfrak{m} \cap U = \emptyset$. Now $\mathfrak{p} \subseteq \mathfrak{m}$ implies $\mathfrak{n} = \mathfrak{p}_u \subseteq \mathfrak{m}_u \neq R_u$. Suppose we had $1/1 \in \mathfrak{m}_u$ then there were some $m \in \mathfrak{m}$ and $k \in \mathbb{N}$ such that $1/1 = m/u^k$ which is $u^{k+j} = u^j m$ for some $j \in \mathbb{N}$. But as $u^{k+j} \notin \mathfrak{m}$, this cannot be. Hence $\mathfrak{m}_u$ is proper and as $\mathfrak{n}$ is maximal, this implies $\mathfrak{n} = \mathfrak{m}_u$. That is $\mathfrak{m} \mapsto \mathfrak{n}$ and hence the surjectivity.

- Consider any prime ideal $\mathfrak{q} \trianglelefteq_{\mathrm{i}} R_u$ then we have to prove that $\mathfrak{q}$ is the intersection of all maximal ideals $\mathfrak{n} \trianglelefteq_{\mathrm{i}} R_u$ containing $\mathfrak{q} \subseteq \mathfrak{n}$. But by the correspondence theorem (2.129) there is a prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ with $u \notin \mathfrak{p}$ such that $\mathfrak{q} = \mathfrak{p}_u$. And by the above there is a maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ such that $u \notin \mathfrak{m}$ such that $\mathfrak{n} = \mathfrak{m}_u$. That is we have to prove

$$\mathfrak{p}_u \;=\; \bigcap \{\, \mathfrak{m}_u \in \mathrm{Smax}(R_u) \mid \mathfrak{p}_u \subseteq \mathfrak{m}_u \,\}$$

As the intersection runs over maximal (hence prime) ideals satisfying $\mathfrak{m} \cap U = \emptyset$ it interchanges with the localisation U^{-1} according to (2.127). Thus due to the correspondence it suffices to verify the following identity in the base ring R

$$\mathfrak{p} \;=\; \bigcap \{\, \mathfrak{m} \in \mathrm{Smax}(R) \mid \mathfrak{p} \subseteq \mathfrak{m},\, u \notin \mathfrak{m} \,\}$$

As R is jacobson we know that $\mathfrak{p}$ is the intersection of *all* maximal ideals $\mathfrak{m}$ containing $\mathfrak{p} \subseteq \mathfrak{m}$. The above set is a subset of this and hence we have $\mathfrak{p} = \bigcap \{\, \mathfrak{m} \mid \mathfrak{p} \subseteq \mathfrak{m} \,\} \subseteq \bigcap \{\, \mathfrak{m} \mid \mathfrak{p} \subseteq \mathfrak{m}, u \notin \mathfrak{m} \,\}$. It remains to check the converse inclusion: Consider any $a \in R$ that is contained in any $\mathfrak{m}$ of the form $\mathfrak{p} \subseteq \mathfrak{m}$ and $u \notin \mathfrak{m}$. Suppose we had $a \notin \mathfrak{p}$ then there would have to be some $\mathfrak{m}$ with $\mathfrak{p} \subseteq \mathfrak{m}$ such that $a \notin \mathfrak{m}$ and $u \in \mathfrak{m}$. But then $au \in \mathfrak{m}$ for any $\mathfrak{m}$ with $u \in \mathfrak{m}$ and also $au \in \mathfrak{m}$ for any $\mathfrak{m}$

with $\mathfrak{p} \subseteq \mathfrak{m}$ and $u \notin \mathfrak{m}$, by assumption. Hence

$$au \in \left(\bigcap_{\substack{\mathfrak{p} \subseteq \mathfrak{m} \\ u \notin \mathfrak{m}}} \mathfrak{m} \right) \cap \left(\bigcap_{u \in \mathfrak{m}} \mathfrak{m} \right) \subseteq \bigcap_{\mathfrak{p} \subseteq \mathfrak{m}} \mathfrak{m} = \mathfrak{p}$$

As $au \in \mathfrak{p}$, $\mathfrak{p}$ is prime and $u \notin \mathfrak{p}$ we conclude $a \in \mathfrak{p}$. But this is the converse inclusion and hence we have the above equality for $\mathfrak{p}$ as an intersection. This yields the above equality for $\mathfrak{p}_u$ and this is the Jacobson property for R_u.

(iii) Let us first regard the case that S is a Jacobson ring, then we prove, that R is a Jacobson ring, too: To do this we have to regard any prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ and have to show

$$\mathfrak{p} = \mathfrak{a} \quad \text{where} \quad \mathfrak{a} := \bigcap \{ \mathfrak{m} \in \operatorname{Smax}(R) \mid \mathfrak{p} \subseteq \mathfrak{m} \}$$

As $\mathfrak{p} \subseteq \mathfrak{a}$ is clear it suffices to check the converse inclusion: That is we assume $u \in \mathfrak{a} \setminus \mathfrak{p}$ and and aim for a contradiction. By the lying-over theorem (8.32.(i)) there is a prime ideal $\mathfrak{q} \trianglelefteq_{\mathrm{i}} S$ such that $\mathfrak{p} = \mathfrak{q} \cap R = \alpha^{-1}(\mathfrak{q}) = \{ a \in R \mid a1_S \in \mathfrak{q} \}$. As S is a Jacobson ring, we have

$$\mathfrak{q} = \mathfrak{b} \quad \text{where} \quad \mathfrak{b} := \bigcap \{ \mathfrak{n} \in \operatorname{Smax}(S) \mid \mathfrak{q} \subseteq \mathfrak{n} \}$$

If we had $u1_S \in \mathfrak{q}$, then $u \in \mathfrak{q} \cap R = \mathfrak{p}$, which is not the case and therefore $u1_S \notin \mathfrak{q}$. As $\mathfrak{q} = \mathfrak{b}$ there has to be some $\mathfrak{n} \in \operatorname{Smax}(S)$ with $\mathfrak{q} \subseteq \mathfrak{n}$ and $u1_S \notin \mathfrak{n}$. Let $\mathfrak{m} := \mathfrak{n} \cap R$, which is a maximal ideal of R, due to (8.32.(ii)). The inclusion $\mathfrak{q} \subseteq \mathfrak{n}$ also implies $\mathfrak{p} = \mathfrak{q} \cap R \subseteq \mathfrak{n} \cap R = \mathfrak{m}$ By definition $u \in \mathfrak{m}$ would mean $u1_S \in \mathfrak{n}$, which is not the case, therefore $u \notin \mathfrak{m}$. But as $\mathfrak{p} \subseteq \mathfrak{m}$ and $\mathfrak{m}$ is a maximal ideal, this contradicts $u \in \mathfrak{a}$ and hence there cannot be some $u \in \mathfrak{a} \setminus \mathfrak{p}$, such that $\mathfrak{a} \subseteq \mathfrak{p}$, too.

- Consider any prime ideal $\mathfrak{q} \trianglelefteq_{\mathrm{i}} S$, we have to prove, that $\mathfrak{q} = \mathfrak{b}$ where $\mathfrak{b} := \bigcap \{ \mathfrak{n} \in \operatorname{Smax}(S) \mid \mathfrak{q} \subseteq \mathfrak{n} \}$. Thereby it is clear, that $\mathfrak{q} \subseteq \mathfrak{b}$ as any $\mathfrak{n}$ contains $\mathfrak{q}$. Take $\mathfrak{p} := \mathfrak{q} \cap R$, then $\mathfrak{p}$ is a prime ideal, as $\mathfrak{q}$ was some. Now define

$$\mathcal{M} := \{ \mathfrak{m} \in \operatorname{Smax}(R) \mid \mathfrak{p} \subseteq \mathfrak{m} \} \quad \text{and} \quad \mathfrak{a} := \bigcap \mathcal{M}$$

As R is jacobson, by assumption, we have $\mathfrak{p} = \mathfrak{a}$. Next we aim to prove $\mathfrak{a} = \mathfrak{b} \cap R$, so let us take a look at the pull back of $\mathfrak{b}$: As $\mathfrak{n} \cap R = \alpha^{-1}(\mathfrak{n})$ is the pre-image of $\mathfrak{n}$ this operation commutes with intersections - according to (0.7) - and hence

$$\mathfrak{b} \cap R = \bigcap \mathcal{N} \quad \text{where} \quad \mathcal{N} := \{ \mathfrak{n} \cap R \mid \mathfrak{n} \in \operatorname{Smax}(S), \mathfrak{q} \subseteq \mathfrak{n} \}$$

For $\mathfrak{a} \subseteq \mathfrak{b} \cap R$ we start with some $a \in \mathfrak{a}$ and have to prove $a \in \mathfrak{n} \cap R$ for any $\mathfrak{n} \cap R \in \mathcal{N}$. As $\mathfrak{n} \trianglelefteq_{\mathrm{i}} S$ is maximal and $S : R$ is integral $\mathfrak{m} := \mathfrak{n} \cap R$ is maximal, too - due to lying-over (8.32.(ii)). And from $\mathfrak{q} \subseteq \mathfrak{n}$ we clearly get $\mathfrak{p} = \mathfrak{q} \cap R \subseteq \mathfrak{n} \cap R = \mathfrak{m}$ such that $\mathfrak{m} \in \mathcal{M}$. As $a \in \mathfrak{a} = \bigcap \mathcal{M} \subseteq \mathfrak{m}$ we conclude $a \in \mathfrak{m}$. As this is true for any $\mathfrak{n} \cap R$ we have $a \in \mathfrak{b} \cap R$, and $\mathfrak{a} \subseteq \mathfrak{b} \cap R$, as a has been arbitrary.

Conversely for $\mathfrak{b} \cap R \subseteq \mathfrak{a}$ we start with some $a \in \mathfrak{b} \cap R$ and have to show $a \in \mathfrak{m}$ for any $\mathfrak{m} \in \mathcal{M}$.

If $\mathfrak{p}$ is maximal itself, then $\mathfrak{q}$ is maximal, by (8.32.(ii)) such that $\mathcal{N} = \{\mathfrak{q} \cap R\} = \{\mathfrak{p}\} = \mathcal{M}$. In particular $\mathfrak{b} \cap R = \mathfrak{a}$ in this case. If $\mathfrak{p}$ is not maximal then any $\mathfrak{m} \in \mathcal{M}$ gives rise to a CPI $\mathfrak{p} \subset \mathfrak{m}$. As we have $\mathfrak{p} = \mathfrak{q} \cap R$ we can use going up (8.72.(ii)) to find a CPI $\mathfrak{q} \subset \mathfrak{n}$ with $\mathfrak{n} \cap R = \mathfrak{m}$. As $\mathfrak{m}$ is maximal, so is $\mathfrak{n}$ by (8.32.(ii)) again. Thus we have $\mathfrak{n} \cap R \in \mathcal{N}$ and therefore $a \in \mathfrak{b} \cap R = \bigcup \mathcal{N} \subseteq \mathfrak{n} \cap R$, which implies $a \in \mathfrak{n} \cap R = \mathfrak{m}$. Again, as $a \in \mathfrak{m}$ is true for any $\mathfrak{m} \in \mathcal{M}$ we get $a \in \mathfrak{a}$ and as $a \in \mathfrak{b} \cap R$ was arbitrary, we also conclude $\mathfrak{b} \cap R \subseteq \mathfrak{a}$.

Now that we have $\mathfrak{a} = \mathfrak{b} \cap R$ we are almost done: Recall that $\mathfrak{q} \subseteq \mathfrak{b}$ and we have just seen $\mathfrak{q} \cap R = \mathfrak{p} = \mathfrak{a} = \mathfrak{b} \cap R$. Also $\mathfrak{p}$ is prime such that by (8.32.(iv)) we conclude $\mathfrak{q} = \mathfrak{b}$, which was required for R to be a Jacobson ring.

□

Proof of (8.88):

(i) By definition the closure of P is the intersection of all closed sets of X containing P. The closed sets of X are of the form $\mathbb{V}(\mathfrak{a})$ for some ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$. That is we have

$$\overline{P} \;=\; \bigcap \{\, \mathbb{V}(\mathfrak{a}) \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} R,\, P \subseteq \mathbb{V}(\mathfrak{a}) \,\}$$

Hereby $P \subseteq \mathbb{V}(\mathfrak{a})$ translates into: For any $\mathfrak{p} \in P$ we have $\mathfrak{a} \subseteq \mathfrak{p}$. Thus if $P \subseteq \mathbb{V}(\mathfrak{a})$ then $\mathfrak{a} \subseteq \mathbb{I}(P)$. And conversely if $\mathfrak{a} \subseteq \mathbb{I}(P)$ then $\mathbb{V}\mathbb{I}(P) \subseteq \mathbb{V}(\mathfrak{a})$, as $\mathbb{V}$ is order reversing. But also any $\mathfrak{p} \in P$ satisfies $\mathbb{I}(P) \subseteq \mathfrak{p}$ and thereby $P \subseteq \mathbb{V}\mathbb{I}(P) \subseteq \mathbb{V}(\mathfrak{a})$. That is $P \subseteq \mathbb{V}(\mathfrak{a})$ and $\mathfrak{a} \subseteq \mathbb{I}(P)$ are equivalent and thus we have found

$$\overline{P} \;=\; \bigcap \{\, \mathbb{V}(\mathfrak{a}) \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} R,\, \mathfrak{a} \subseteq \mathbb{I}(P) \,\}$$

So clearly $\mathfrak{a} = \mathbb{I}(P)$ is part of the intersection and thereby $\overline{P} \subseteq \mathbb{V}(\mathbb{I}(P))$. If conversely $\mathfrak{a} \subseteq \mathbb{I}(P)$, then $\mathbb{V}\mathbb{I}(P) \subseteq \mathbb{V}(\mathfrak{a})$, as $\mathbb{V}$ is order-reversing. As this is true for any $\mathfrak{a}$ we have $\mathbb{V}\mathbb{I}(P) \subseteq \overline{P}$ such that these sets are equal.

(ii) If $\mathfrak{m} \in \mathrm{Smax}(R)$ is a maximal ideal, then there is no proper ideal (apart from $\mathfrak{m}$ itself) containing $\mathfrak{m}$ - this is what being maximal is all about. Thus we have $\mathbb{V}(\mathfrak{m}) = \{\mathfrak{m}\}$. And as set of the form $\mathbb{V}(\mathfrak{m})$ are closed by definition, $\mathfrak{m}$ is a closed point. Conversely let $\mathfrak{p} \in X$ be a closed point, that is $\{\mathfrak{p}\}$ is closed. Then the closure of $\{\mathfrak{p}\}$ is $\{\mathfrak{p}\}$ again. But by (i) the closure of $\{\mathfrak{p}\}$ is given to be

$$\{\mathfrak{p}\} \;=\; \overline{\{\mathfrak{p}\}} \;=\; \mathbb{V}\big(\mathbb{I}(\{\mathfrak{p}\})\big) \;=\; \mathbb{V}(\mathfrak{p})$$

Let $\mathfrak{m} \in \mathrm{Smax}(R)$ be a maximal ideal containing $\mathfrak{p} \subseteq \mathfrak{m}$, then $\mathfrak{m} \in \mathbb{V}(\mathfrak{p}) = \{\mathfrak{p}\}$ and hence $\mathfrak{m} = \mathfrak{p}$. In particular $\mathfrak{p}$ is maximal, itself.

(iii) Let us first check $B(a) = X \setminus \mathbb{V}(aR)$: If $\mathfrak{p} \in X$ such that $a \notin \mathfrak{p}$ then $a \in aR \subseteq \mathfrak{p}$ is false, such that $\mathfrak{p} \notin \mathbb{V}(aR)$. Conversely if $aR \subseteq \mathfrak{p}$ is false, then there is some $b \in R$ such that $ab \notin \mathfrak{p}$. In particular $a \notin \mathfrak{p}$, as $\mathfrak{p}$ is an ideal. Now that $B(a) = X \setminus \mathbb{V}(aR)$, we see that $B(a)$ is open. Also $B(1) = X$, as $1 \in \mathfrak{p}$ would imply $\mathfrak{p} = R$. Also for any a, $b \in R$ and any $\mathfrak{p} \in X$ we have $ab \in \mathfrak{p}$ equivalent to $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$, as $\mathfrak{p}$ is a prime ideal. The negation thereof is $ab \notin \mathfrak{p}$ respectively

$a \notin \mathfrak{p}$ and $b \notin \mathfrak{p}$. Thus we have the identity

$$B(a) \cap B(b) \;=\; B(ab)$$

Thus $\mathcal{B}$ is the base of a topology on X. Let us check, that this is the Zariski-topology: Consider any open set $U = X \setminus \mathbb{V}(\mathfrak{a})$, then we will argue, that

$$U \;=\; \bigcup_{a \in \mathfrak{a}} B(a)$$

If $\mathfrak{p} \in U$ then $\mathfrak{a} \subseteq \mathfrak{p}$ is false. That is there is some $a \in \mathfrak{a}$ with $a \notin \mathfrak{p}$ and this is $\mathfrak{p} \in B(a)$. Conversely if $\mathfrak{p} \in B(a)$ for some $a \in \mathfrak{a}$, then for the same reason $\mathfrak{a} \subseteq \mathfrak{p}$ is false, such that $\mathfrak{p} \in U$.

(iv) Suppose there is some $a \in \mathfrak{p}$ such that $a \notin \mathfrak{q}$, then we have $\mathfrak{q} \in B(a)$ and $\mathfrak{p} \notin B(a)$. Thus by taking $U = B(a)$ we are done. If there is no such a, then $\mathfrak{p} \subseteq \mathfrak{q}$. Yet as $\mathfrak{p} \neq \mathfrak{q}$ this means $\mathfrak{p} \subset \mathfrak{q}$. In particular there is some $b \in \mathfrak{q}$ with $b \notin \mathfrak{p}$. Thus by $U := B(b)$ we get $\mathfrak{p} \in U$ and $\mathfrak{q} \notin B(b)$ and hence can close this case, too.

(v) To say $U_i \subseteq X$ is open, means that there is an ideal $\mathfrak{a}_i \trianglelefteq_{\mathfrak{i}} R$, such that $U_i = X \setminus \mathbb{V}(\mathfrak{a}_i)$. By assumption the U_i cover X and thereby we can compute

$$X \;=\; \bigcup_{i \in I} U_i \;=\; \bigcup_{i \in I} X \setminus \mathbb{V}(\mathfrak{a}_i) \;=\; X \setminus \bigcap_{i \in I} \mathbb{V}(\mathfrak{a}_i) \;=\; X \setminus \mathbb{V}\left(\sum_{i \in I} \mathfrak{a}_i \right)$$

Let us abbreviate the sum of the $\mathfrak{a}_i$ by $\mathfrak{a}$. Then the above identity means $\mathbb{V}(\mathfrak{a}) = \emptyset$. If we had $\mathfrak{a} \neq R$, then there was a maximal ideal $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} R$ containing $\mathfrak{a} \subseteq \mathfrak{m}$. In particular $\mathfrak{m} \in \mathbb{V}(\mathfrak{a}) = \emptyset$, a contradiction. Thus we find $\mathfrak{a} = R$ and hence $1 \in \mathfrak{a}$. By construction this means that there is a finite subset $\Omega = \{ i(1), \ldots, i(n) \} \subseteq I$ such that $1 = a_{i(1)} + \cdots + a_{i(n)}$ for some $a_{i(k)} \in \mathfrak{a}_{i(k)}$. But then any ideal containing $a_{i(1)} + \cdots + a_{i(n)}$ would contain 1 and hence $\mathbb{V}(a_{i(1)} + \cdots + a_{i(n)}) = \emptyset$. From this we can return in a like manner

$$X \;=\; X \setminus \emptyset \;=\; X \setminus \mathbb{V}\left(\sum_{i \in \Omega} \mathfrak{a}_i \right) \;=\; X \setminus \bigcap_{i \in \Omega} \mathbb{V}(\mathfrak{a}_i) \;=\; \bigcup_{i \in \Omega} X \setminus \mathbb{V}(\mathfrak{a}_i) \;=\; \bigcup_{i \in \Omega} U_i$$

(vi) If $\mathfrak{u} \in \operatorname{Spec}(S)$ is a prime ideal, then $\varphi^{-1}(\mathfrak{u})$ is a prime ideal of R, as we have seen in (2.17). Also if $C := \mathbb{V}(\mathfrak{a})$ is a closed set of X, then $\varphi_*^{-1}(C) = \mathbb{V}(\mathfrak{u})$, where $\mathfrak{u} := \mathfrak{a}S$ is the ideal of S generated by $\varphi(\mathfrak{a})$. This has been shown in (2.17), as well. In particular $\varphi_*^{-1}(C) \subseteq Y$ is closed again and hence φ_* is a continuous map.

(vii) By (vi) the canonical map $\varrho : R \twoheadrightarrow R/\mathfrak{a} : b \mapsto b + \mathfrak{a}$ induces a continuous map ϱ^* on the spectra. And this is given to be $\varrho^{-1}(\mathfrak{p}/\mathfrak{a}) = \{ b \in R \mid b + \mathfrak{a} \in \mathfrak{p}/\mathfrak{a} \} = \{ b \in R \mid b \in \mathfrak{p} \} = \mathfrak{p}$. And from this it is clear, that ϱ^{-1} is injective. It remains to prove, that ϱ^{-1} also is closed: By the correspondence theorem (1.71) of ideals we have $\operatorname{Spec}(R/\mathfrak{a}) = \{ \mathfrak{p}/\mathfrak{a} \mid \mathfrak{p} \in \mathbb{V}(\mathfrak{a}) \}$. As the ideals of $R/\mathfrak{a}$ are of the form $\mathfrak{b}/\mathfrak{a}$ for some ideal $\mathfrak{b} \trianglelefteq_{\mathfrak{i}} R$ with $\mathfrak{a} \subseteq \mathfrak{b}$, a closed subset of $\operatorname{Spec}(R/\mathfrak{a})$ is of the form $\mathbb{V}(\mathfrak{b}/\mathfrak{a})$ and this is mapped to $\mathbb{V}(\mathfrak{b})$ under ϱ^*. In particular ϱ^* is a closed map, as well.

(viii) By (vi) the canonical map $\kappa : R \to U^{-1}R : a \mapsto a/1$ induces a continuous map κ^* on the spectra.

If $\widetilde{\mathfrak{p}}$ is an ideal of $U^{-1}R$ then it is of the form $\widetilde{\mathfrak{p}} = U^{-1}\mathfrak{p} = \{ p/u \mid p \in \mathfrak{p}, u \in U \}$ for some prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ that satisfies $\mathfrak{p} \cap U = \emptyset$. This has been proved in (2.129). We then get $\kappa^*(\widetilde{\mathfrak{p}}) = \kappa^{-1}(\widetilde{\mathfrak{p}}) = \{ a \in R \mid a/1 \in \widetilde{\mathfrak{p}} \} = \{ a \in R \mid a \in \mathfrak{p} \} = \mathfrak{p}$. And from this it is clear that κ^* is injective. A general ideal of $U^{-1}R$ is of the form $\widetilde{\mathfrak{a}} = \{ a/u \mid a \in \mathfrak{a}, u \in U \}$ for some ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ (with $\mathfrak{a} = \mathfrak{a} : U$). Thus a closed set of $\mathrm{Spec}(U^{-1}R)$ is of the form $\mathbb{V}(\widetilde{\mathfrak{a}})$ and if $\widetilde{\mathfrak{p}}$ is a prime ideal of $U^{-1}R$ with $\widetilde{\mathfrak{a}} \subseteq \widetilde{\mathfrak{p}}$ then $\widetilde{\mathfrak{p}}$ is mapped to $\mathfrak{p}$ that satisfies $\mathfrak{a} \subseteq \mathfrak{p}$. Conversely if $\mathfrak{a} \subseteq \mathfrak{p}$ then $U^{-1}\mathfrak{a} \subseteq U^{-1}\mathfrak{p}$ such that $\kappa^*(\mathbb{V}(\widetilde{\mathfrak{a}}) = \mathbb{V}(\mathfrak{a})$, which means that κ^* is a closed map. Altogether κ^* is a homeomorphism, when restricted to its image.

□

Proof of (8.89):

(i) By construction $B(u) = X \setminus \mathbb{V}(uR)$ such that $B(v) \subseteq B(u)$ turns into $\mathbb{V}(uR) \subseteq \mathbb{V}(vR)$ and this again is $\mathbb{I}\{\,(\,\}\, vR) \subseteq \mathbb{IV}(uR)$. Thus we see $v \in \sqrt{vR} = \sqrt{uR}$ such that $v^n \in uR$ for some $n \in \mathbb{N}$. And this again means $v^n = up$ for some $p \in R$.

(ii) We have to check the well-definedness, the homomorphism property then is obvious from the construction. So consider any $a/u^r = b/u^s$, that is there is some $t \in \mathbb{N}$ such that $u^t u^s a = u^t u^r b$. Multiplying this equation by p^{r+s+t} we then get

$$p^{r+s+t}u^t u^s a \;=\; (up)^t (up)^s p^r a \;=\; v^{nt} v^{ns} p^r a$$

$$p^{r+s+t}u^t u^r b \;=\; (up)^t (up)^r p^s b \;=\; v^{nt} v^{nr} p^s b$$

As the left-hand side of these equations is identical, we get $p^r a/v^{nr} = p^s b/v^{ns}$ from the right-hand side, of these equations and this is the well-definedness of ϱ_u^v. Let us verify, that this homomorphism truly is independent of the choice of n and p. That is consider $v^{n_1} = up_1$ and $v^{n_2} = up_2$ then we have to verify (for any $a/u^m \in R_u$), that

$$\frac{ap_1^m}{v^{mn_1}} \;=\; \frac{ap_2^m}{v^{mn_2}}$$

Hence we regard

$$v^{mn_2} a p_1^m \;=\; (v^{n_2})^m a p_1^m \;=\; (up_2)^m a p_1^m \;=\; p_1^m p_2^m a u^m$$
$$v^{mn_1} a p_2^m \;=\; (v^{n_1})^m a p_2^m \;=\; (up_1)^m a p_2^m \;=\; p_1^m p_2^m a u^m$$

As the right-hand sides of these equations are identical, so are the left-hand sides, and from this we get $ap_1^m/v^{mn_1} = ap_2^m/v^{mn_2}$. Thus the construction of $\varrho_u^v(a/u^m)$ yields the same element of R_v regardless of the specific n and p chosen.

(iii) We will prove $\varrho_v^u \varrho_u^v(a/u^k) = a/u^k$ for any $a/u^k \in R_u$. That is $\varrho_v^u \varrho_u^v$ is the identity map of R_u and by the symmetry of the argument, we also find that $\varrho_u^v \varrho_v^u$ is the identity on R_v. To do this let $u^m = qv$ and $v^n = pu$, then we have to verify, that

$$\frac{a}{u^k} \;=\; \varrho_v^u \varrho_u^v \left(\frac{a}{u^k}\right) \;=\; \varrho_v^u \left(\frac{ap^k}{v^{km}}\right) \;=\; \frac{ap^k q^{kn}}{u^{knm}}$$

But this, we get from $u^{knm}a = (u^m)^{kn}a = (qv)^{kn}a = q^{kn}(v^n)^k a = q^{kn}(pu)^k a = u^k a p^k q^{kn}$. And in the localisation R_u this turns into the above identity $a/u^k = a^k q^{kn}/u^{knm}$ needed.

(iii) Now consider $B(w) \subseteq B(v) \subseteq B(u)$, then by (i) we find $v^m = pu$ and $w^n = qv$ for some m, $n \in \mathbb{N}$ and p, $q \in R$. From this we see $w^{mn} = q^m v^m = q^m pw$ such that ϱ_u^w can be described as

$$\varrho_u^w\left(\frac{a}{u^k}\right) \;=\; \frac{a(q^m p)^k}{(w^{mn})^k} \;=\; \frac{aq^{km}p^k}{w^{kmn}}$$

Comparing this to the composition $\varrho_v^w \varrho_u^v$ we find, that these maps are identical, as

$$\varrho_v^w \varrho_u^v\left(\frac{a}{u^k}\right) \;=\; \varrho_v^w\left(\frac{ap^k}{v^{km}}\right) \;=\; \frac{(ap^k)q^{km}}{v^{kmn}} \;=\; \varrho_u^w\left(\frac{a}{u^k}\right)$$

□

Proof of (8.90):

- (a) $\Longrightarrow$ (b) can be proved by induction on n: For $n = 1$ the claim is trivial, so consider $n \geq 2$ and define $C := C_1$ and $D := C_2 \cup \cdots \cup C_n$. Let us first assume $C = C_1 \cup \cdots \cup C_n = C \cup D$, then by the irreducibility of I it follows that $I = C$ or $I = D$. In the first case $I = C_1$ we are done. In the latter case $I = C_2 \cup \cdots \cup C_k$ we find some $k \in 2 \ldots n$ with $I = C_k$, by induction hypothesis. Together we have proved the induction step and hence (b).

- (b) $\Longrightarrow$ (c) is quite obvious: We start with $I \subseteq C_1 \cup \cdots \cup C_n$ for some closed sets $C_i \subseteq X$. In this case simply let $B_i := C_i \cap I$, which are closed subsets of I. Then we get $I = B_1 \cup \cdots \cup B_n$ and by assumption (b) there is some $k \in 1 \ldots n$ such that $I = B_k$. But from $I = B_k = C_k \cap I$ we conclude $I \subseteq C_k$ again, which is (c).

- For the converse direction (c) $\Longrightarrow$ (a) we consider closed subsets C, $D \subseteq I$ such that $I = C \cup D$. That is $C = C' \cap I$ resp. $D = D' \cap I$ for some closed sets C', $D' \subseteq X$. As $I = C \cup D = (C' \cap I) \cup (D' \cup I) = (C' \cup D') \cap I$ we have $I \subseteq C' \cup D'$ and hence by assumption (c), without loss of generality, $I \subseteq C'$. This again is $I = C' \cap I = C$.

- (a) $\Longrightarrow$ (d): Let $C := I \setminus U$ and $D := I \setminus V$, then C and D are closed subsets of I and since U and V are non-empty we have $C \neq I$ and $D \neq I$. Thus by (a) we have $I \neq B \cup C$, which yields the claim by going to complements

$$\emptyset \;=\; I \setminus I \;\neq\; I \setminus (C \cup D) \;=\; (I \setminus C) \cap (I \setminus D) \;=\; U \cap V$$

- (d) $\Longrightarrow$ (e): Let $V := I \setminus \overline{U}$ where $\overline{U}$ denotes the closure of U in I. Then clearly V is an open subset of I and we have $U \cap V = \emptyset$ (as $x \in V$ is just $x \notin \overline{U}$, in particular $x \notin U$ since $U \subseteq \overline{U}$). By (b) and the assumption $U \neq \emptyset$ we find $V = \emptyset$, which is $\overline{U} = I$.

- (e) $\Longrightarrow$ (d): Consider non-empty, open subsets U, $V \subseteq I$ and let $D := I \setminus V$. If $U \cap V = \emptyset$, then clearly $U \subseteq D$. But D is closed in I and $U \neq \emptyset$ by assumption, such that $D \neq \emptyset$, too. Now (c) implies that $D = I$ and hence $V = \emptyset$ in contradiction to V being non-empty.

- (d) $\implies$ (a): Suppose $I = C \cup D$ for some closed subsets $C, D \subseteq I$ and let $U := I \setminus C$ and $V := I \setminus D$. Then U and V are open subsets of I and $I = C \cap D$ yields $U \cap V = \emptyset$ by going to complements. Hence by (b) we get $U = \emptyset$ or $V = \emptyset$ and this is nothing but $C = I$ or $D = I$.

- Pick up any $x \in X$ and let $I_x := \overline{\{ x \}} \subseteq X$. By construction I_x is closed and we now prove, that I_x also is irreducible: Suppose $I_x = C \cup D$ for some closed subsets $C, D \subseteq I$. As $x \in I$ we have $x \in C$ or $x \in D$. Without loss of generality we assume $x \in C$, that is $\{ x \} \subseteq C$. As $C \subseteq I_x$ and $I_x \subseteq X$ are closed, so is $C \subseteq X$ and thereby $I_x = \overline{\{ x \}} \subseteq C \subseteq I_x$. That is $C = I_x$, which is the irreducibility of I_x.

- Let us now prove, that is a T_0-space we get $I_x = I_y \implies x = y$: Suppose $x \neq y$ then by assumption there is an open set $P \subseteq X$ such that $x \in P$ and $y \notin P$ (we may assume this without loss of generality, as the other case $y \in P$ and $x \notin P$ is analogous). Now let $C := I_y \setminus U$, then $\{ y \} \subseteq C$ and hence $x \in I_x = I_y \subseteq C$, as C is closed. But this yields $x \notin U$, a contradiction.

□

Proof of (8.91):

(i) (a) $\implies$ (b): Suppose $\overline{I} = C \cup D$ for some closed sets $C, D \subseteq \overline{I}$. Hence $C, D \subseteq X$ are closed, such that $C \cap I$ and $D \cap I \subseteq I$ are closed, too. Now regard

$$I \;=\; (C \cap I) \cup (D \cap I)$$

As both of these sets are closed and I was assumed to be irreducible, we may take (without loss of generality again) $I = C \cap I$. In other words $I \subseteq C \subseteq \overline{I}$. And from this we get $\overline{I} \subseteq \overline{C} = C \subseteq \overline{I}$ (where the closure is taken in X) which is $C = \overline{I}$ and hence $\overline{I}$ is irreducible.

- (b) $\implies$ (a): Suppose $I = C \cup D$ for some closed subsets $C, D \subseteq I$. Then the closure (in X) satisfies $\overline{I} = \overline{C \cup D} = \overline{C} \cup \overline{D}$. As $\overline{I}$ was assumed to be irreducible we may assume, without loss of generality, that $\overline{I} = \overline{C}$. But as C has been closed in I we have $C = I \cap \overline{C} = I \cap \overline{I} = I$, which means that I is irreducible.

- The implication (c) $\implies$ (a) is clear (just let $P := I$). For the converse implication (a) $\implies$ (c) consider any open subset $P \subseteq I$. If $\emptyset \neq P', P'' \subseteq P$ are open, then $\emptyset \neq P', P'' \subseteq I$ are open and hence $P' \cap P'' \neq \emptyset$, due to the irreducibility of I. But this means that P is irreducible.

(ii) We will prove this by zornification: Let $\mathcal{Z} := \{ J \in \mathcal{I}(X) \mid I \subseteq J \}$. In particular $\mathcal{Z} \neq \emptyset$ is non-empty, as $I \in \mathcal{Z}$. And $\mathcal{Z}$ is partially ordered under $\subseteq$. We will now prove, that every chain in $\mathcal{Z}$ has a maximal element: Suppose $(J_\lambda) \subseteq \mathcal{Z}$ (where $\lambda \in \Lambda$) is a chain of irreducible sets containing I. Then we let $J := \bigcup_\lambda J_\lambda$. Now consider some non-empty, open subsets $P, Q \subseteq J$ (that is $P = P' \cap J$ and $Q = Q' \cap J$ for some open subsets $P', Q' \subseteq X$). Then we let $P_\lambda := P' \cap J_\lambda$ and $Q_\lambda := Q' \cap J_\lambda$ which are open subsets of J_λ. It is clear that $\bigcup_\lambda P_\lambda = P' \cap J = P$ and $\bigcup_\lambda Q_\lambda = Q' \cap J = Q$ and also $P_\lambda \cap Q_\lambda = P' \cap Q' \cap J_\lambda \subseteq P' \cap Q' \cap J = P \cap Q$. As $P \neq \emptyset$ there has to be some $\lambda \in \Lambda$ such that $P_\lambda \neq \emptyset$ and likewise there is some $\mu \in \Lambda$ such that $Q_\mu \neq \emptyset$. As (J_λ) is a chain we may assume (without loss of generality) that $J_\lambda \subseteq J_\mu$. Now suppose $P \cap Q = \emptyset$ then also $P_\mu \cap Q_\mu = \emptyset$. But as J_μ is irreducible and $Q_\mu \neq \emptyset$, this can only be if $P_\mu = \emptyset$. As $J_\lambda \subseteq J_\mu$ this

implies $P_\lambda \subseteq P_\mu = \emptyset$, a contradiction. Hence $P \cap Q \neq \emptyset$ which means that J is irreducible and thereby $J \in \mathcal{Z}$ is an upper bound of (J_λ). Thus by the lemma of Zorn there is a maximal element $J \in \mathcal{Z}$ and being maximal means that $J \in \operatorname{IRR}(X)$ is an irreducible component.

(iii) Suppose I was *not* connected, then there would be a subset $C \subseteq I$ that is both open and closed and neither $\emptyset$ nor I. Let $D := I \setminus C$, as C is open, $D \subseteq I$ is closed. Also $D \neq I$, as $C \neq \emptyset$. But $I = C \cup D$ is clear and both C, $D \neq I$ this means that I is not irreducible.

(iv) Suppose $f(I) = C \cup D$ for some closed subsets C, $D \subseteq f(I)$. That is $C = C' \cap f(I)$ and $D = D' \cap f(I)$ for some closed subsets C' and $D' \subseteq Y$. Hence $f(I) \subseteq C' \cup D'$ which implies

$$I \subseteq f^{-1}(f(I)) \subseteq f^{-1}(C' \cup D') = f^{-1}(C') \cup f^{-1}(D')$$

As f is continuous and C', $D' \subseteq Y$ are closed, so are $f^{-1}(C')$ and $f^{-1}(D') \subseteq X$. But as I is irreducible property (d) in (i) implies, that (without loss of generality) $I \subseteq f^{-1}(C')$. Hence $f(I) \subseteq f(f^{-1}(C')) \subseteq C'$ which further implies $C \subseteq f(I) \subseteq C' \cap f(I) = C$, that is $f(I) = C$.

(v) Let us first prove, that $\{ x \}$ is closed: Consider any $y \in I_x := \overline{\{ x \}}$ and suppose $x \neq y$. Then - as X is hausdorff - there are open subsets U, $V \subseteq X$ such that $x \in U$, $y \in V$ and $U \cap V = \emptyset$. The $x \in I_x \setminus V$ which is a closed subset of X. As I_x is the smallest closed subset containing x this implies $I_x \setminus V = I_x$ and thereby $y \in I_x \setminus V$, contradicting $y \in V$. Thus y cannot be different from x and this means $I_x = \{ x \}$.

By (8.90) $I_x = \{ x \}$ is an irreducible set and hence, by (ii), there is an irreducible component $I \in \operatorname{IRR}(X)$ containing $I_x \subseteq I$. As before suppose there was some $y \in I$ with $y \neq x$. Then $x \in U$ and $y \in V$ for some open subsets U, $V \subseteq X$ with $U \cap V = \emptyset$. As $x \in U$ and $x \in I_x \subseteq I$ we get $I_x \subseteq U \cap I$, which is an open subset of I. Likewise $y \in V \cap I$ and as I is irreducible and U, V are non-empty, we would conclude $(U \cap I) \cap (V \cap I) \neq \emptyset$. But this contradicts $U \cap V = \emptyset$, such that y cannot be different from x. Again this means $I = \{ x \}$ and thereby $\{ x \}$ is an irreducible component of X.

Conversely, if we start with an irreducible component $I \in \operatorname{IRR}(X)$, then I cannot be $I = \emptyset$ as this would not be maximal. That is $x \in I$ for some $x \in X$ and thereby $\{ x \} \subseteq I$. But as $\{ x \}$ is an irreducible component - that is maximal - we conclude $\{ x \} = I$. That is there are no other irreducible components in X, apart from the one-point sets $\{ x \}$.

□

Proof of (8.93):
Consider any $x \in X$ then $x \in I_x := \overline{\{ x \}}$ and I_x is irreducible. Hence I_x is contained in some irreducible component $I_x \subseteq J \in \operatorname{IRR}(X)$. Therefore we get $x \in \bigcup \operatorname{IRR}(X)$, and as x has been arbitrary this proves $X = \bigcup \operatorname{IRR}(X)$. As $X \neq \emptyset$ is non-empty, there is some $x \in X$. Thus the empty set $\emptyset \subset I_x$ is irreducible, but not maximal. Hence $\emptyset \notin \operatorname{IRR}(X)$. Now consider any irreducible component $I \in \operatorname{IRR}(X)$. In particular I is irreducible, such that $\overline{I}$ is irreducible, too. But from $I \subseteq \overline{I}$ and the maximality of I we get $I = \overline{I}$, that is I is closed. Thus we have proved the first four claims.

If $\mathcal{I} = \operatorname{IRR}(X)$ is the set of irreducible components of X, then the properties (1) and (2) have just been proved. Now suppose $\mathcal{I} = \{ I_1, \ldots, I_r \}$ then we also get property (3): Without loss of generality we will

prove this for $I = I_1$. Suppose $I_1 \subseteq X = I_2 \cup \cdots \cup I_r$, as I_1 is irreducible and any I_j is closed there is some $k \in 2 \ldots r$ such that $I_1 \subseteq I_k$. By the maximality of I_1 this is $I_1 = I_k$, a contradiction. This yields $X \neq I_2 \cup \cdots \cup I_r$ which had to be proved.

Conversely suppose $\mathcal{I} = \{ I_1, \ldots, I_r \}$ is a set satisfying the properties (1), (2) and (3). If $J \in \operatorname{IRR}(X)$ is any irreducible component, then $J \subseteq X = I_1 \cup \cdots \cup I_r$ by (1). As J is irreducible and any I_j is closed by (2), this implies that $J \subseteq I_k$ for some $k \in 1 \ldots r$. But as I_k also is irreducible and J is maximal this yields $J = I_k \in \mathcal{I}$. Hence we have proved $\operatorname{IRR}(X) \subseteq \mathcal{I}$. Now suppose there was any $I \in \mathcal{I}$ that was no irreducible component $I \notin \operatorname{IRR}(X)$. As I is irreducible it is nevertheless contained in an irreducible component $I \subset J \in \operatorname{IRR}(X)$. Hence $X = \bigcup \operatorname{IRR}(X) = \bigcup \{ J \in \mathcal{I} \mid J \neq I \}$ in contradiction to property (3). Hence we truly have $\mathcal{I} = \operatorname{IRR}(X)$. □

Proof of (8.92):

(iii) Let $P := \{ \mathfrak{p} \}$, then $\mathbb{I}(P) = \bigcap P = \mathfrak{p}$ and thereby $\overline{P} = \mathbb{V}\mathbb{I}(P) = \mathbb{V}(\mathfrak{p})$. As the closure of a set that contains one point only is irreducible, by (8.90) we conclude that $\mathbb{V}(\mathfrak{p})$ is irreducible. And $\mathfrak{p}$ is the generic point of $\overline{P} = \mathbb{V}(\mathfrak{p})$, by definition. As $\mathbb{V}(\mathfrak{p})$ is closed, by definition of the Zariski-topology and $\mathfrak{p} \in \mathbb{V}(\mathfrak{p})$ makes $\mathbb{V}(\mathfrak{p})$ non-empty, this already is the implication (a) $\implies$ (b).

Conversely suppose I is non-empty, closed and irreducible. As I is closed, it is of the form $I = \mathbb{V}(\mathfrak{p})$ for some ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$. It remains to prove, that $\mathfrak{p}$ is prime. Suppose we had $\mathfrak{p} = R$, then $I = \mathbb{V}(\mathfrak{p}) = \mathbb{V}(R) = \emptyset$, which was assumed to not be the case. Hence $\mathfrak{p} \neq R$ is a proper ideal. Also, if $a, b \in R$ with $ab \in \mathfrak{p}$, then we have $abR \subseteq \mathfrak{p}$ and thereby $\mathfrak{p} \in \mathbb{V}(abR) = \mathbb{V}(aR) \cup \mathbb{V}(bR)$ according to (2.16). In case $\mathfrak{p} \in \mathbb{V}(aR)$ we have $a \in aR \subseteq \mathfrak{p}$ and thereby $a \in \mathfrak{p}$. Likewise we get $b \in \mathfrak{p}$ in case $\mathfrak{p} \in \mathbb{V}(bR)$. That is $\mathfrak{p}$ truly is a prime ideal of R.

(i) If R is an integral domain, then the zero-ideal $0 \trianglelefteq_{\mathrm{i}} R$ is prime. Hence by (iii) we conclude that $\operatorname{Spec}(R) = \mathbb{V}(0)$ is an irreducible set with generic point 0. Let us also present a more algebraic proof of the statement:

Let us abbreviate $X := \operatorname{Spec}(R)$ and suppose $X = C \cup D$ for some closed subsets $C, D \subseteq X$. That is $C = \mathbb{V}(\mathfrak{a})$ and $D = \{ \} \mathbb{V}(\mathfrak{b})$ for some ideals $\mathfrak{a}, \mathfrak{b} \trianglelefteq_{\mathrm{i}} R$. Then

$$X \;=\; \mathbb{V}(\mathfrak{a}) \cup \mathbb{V}(\mathfrak{b}) \;=\; \mathbb{V}(\mathfrak{a} \cap \mathfrak{b})$$

That is for any prime ideal $\mathfrak{p}$ of R we have $\mathfrak{a} \cap \mathfrak{b} \subseteq \mathfrak{p}$. As R is an integral domain, 0 is a prime ideal and from $\mathfrak{a} \cap \mathfrak{b} \subseteq 0$ we conclude $\mathfrak{a} \cap \mathfrak{b} = 0$. Now suppose there were some $a \in \mathfrak{a}$ and $b \in \mathfrak{b}$ with $a \neq 0$ and $b \neq 0$. As R is an integral domain, this would mean $ab \neq 0$, but also $ab \in \mathfrak{a} \cap \mathfrak{b} = 0$. This contradiction means we cannot have both, $a \neq 0$ and $b \neq 0$, and thereby $\mathfrak{a} = 0$ or $\mathfrak{b} = 0$. But from $\mathfrak{a} = 0$ we get $C = \mathbb{V}(\mathfrak{a}) = X$ and likewise $\mathfrak{b} = 0$ would mean $D = \mathbb{V}(\mathfrak{b}) = X$. That is X is irreducible. And as $\mathbb{I}(\{0\}) = \bigcap\{0\} = 0$ we also find, that

$$\overline{\{0\}} \;=\; \mathbb{V}\mathbb{I}(\{0\}) \;=\; \mathbb{V}(0) \;=\; X$$

(ii) Consider any two elements $a, b \in R$ such that $ab = 0$ and denote the ideals $\mathfrak{a} := aR$ and $\mathfrak{b} := bR$. Again abbreviate $X := \operatorname{Spec}(R)$, which is irreducible, by assumption. If $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ is any prime ideal,

then we distinguish two cases: (1) If $a \in \mathfrak{p}$, then $\mathfrak{a} \subseteq \mathfrak{p}$ and hence $\mathfrak{a} \cap \mathfrak{b} \subseteq \mathfrak{a} \subseteq \mathfrak{p}$. (2) If $a \notin \mathfrak{p}$, then still $ab = 0 \in \mathfrak{p}$ such that $b \in \mathfrak{p}$. But this is $\mathfrak{b} \subseteq \mathfrak{p}$ and hence $\mathfrak{a} \cap \mathfrak{b} \subseteq \mathfrak{b} \subseteq \mathfrak{p}$ again. Thus in both cases, we have $\mathfrak{a} \cap \mathfrak{b} \subseteq \mathfrak{p}$ and thereby

$$X \;=\; \mathbb{V}(\mathfrak{a} \cap \mathfrak{b}) \;=\; \mathbb{V}(\mathfrak{a}) \cup \mathbb{V}(\mathfrak{b})$$

As X is irreducible, we may take $X = \mathbb{V}(\mathfrak{a})$ without loss of generality. That is $\mathfrak{a} \subseteq \mathfrak{p}$ for any prime ideal $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ and thereby

$$\mathfrak{a} \;\subseteq\; \bigcap \mathrm{Spec}(R) \;=\; \textsc{nil}(R) \;=\; 0$$

Thereby $\textsc{nil}(R) = 0$, as R was assumed to be reduced. That is $\mathfrak{a} = 0$ and this is $a = 0$. Thus from $ab = 0$ we conclude $a = 0$ (or $b = 0$ in case $X = \mathbb{V}(\mathfrak{b})$), that is R an integral domain.

(iv) If $I \in \textsc{irr}(X)$ is an irreducible component of $X = \mathrm{Spec}(R)$, then it already is non-empty, closed and irreducible, because of (8.93). Thus from (iii) we get $I = \mathbb{V}(\mathfrak{p})$ for some prime ideal $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$. We have to show that $\mathfrak{p}$ is minimal, that is we assume $\mathfrak{q} \subseteq \mathfrak{p}$ for some $\mathfrak{q} \in X$. Then we would get $\mathbb{V}(\mathfrak{p}) \subseteq \mathbb{V}(\mathfrak{q})$ and as by (iii) $\mathbb{V}(\mathfrak{q})$ is irreducible and $\mathbb{V}(\mathfrak{p})$ is maximal by assumption, this would imply $\mathbb{V}(\mathfrak{p}) = \mathbb{V}(\mathfrak{q})$. In particular $\mathfrak{q} \in \mathbb{V}(\mathfrak{p})$, which is $\mathfrak{p} \subseteq \mathfrak{q}$ and thereby $\mathfrak{p} = \mathfrak{q}$.

Conversely, if $\mathfrak{p} \in \mathrm{Smin}(R)$ is a minimal prime ideal, then we know that $\mathbb{V}(\mathfrak{p})$ is irreducible, by (iii). It remains to prove that $\mathbb{V}(\mathfrak{p})$ is an irreducible component, that is we assume $\mathbb{V}(\mathfrak{p}) \subseteq J$ for some irreducible $J \subseteq X$. As $J \subseteq \overline{J}$ and $\overline{J}$ also is irreducible, by (8.91), we also get $\mathbb{V}(\mathfrak{p}) \subseteq \overline{J}$. As $\mathfrak{p} \in \mathbb{V}(\mathfrak{p})$ we also have $\mathfrak{p} \in \overline{J}$ and hence $\overline{J} \neq \emptyset$. Thus by (iii) we get $\overline{J} = \mathbb{V}(\mathfrak{q})$ for some prime ideal $\mathfrak{q} \in X$. Now $\mathfrak{p} \in \overline{J} = \mathbb{V}(\mathfrak{q})$ means $\mathfrak{q} \subseteq \mathfrak{p}$, but as $\mathfrak{p}$ is minimal, this means $\mathfrak{q} = \mathfrak{p}$ and thereby $\overline{J} = \mathbb{V}(\mathfrak{q}) = \mathbb{V}(\mathfrak{p}) \subseteq J \subseteq \overline{J}$. This combines to $\mathbb{V}(\mathfrak{p}) = J$, which is the maximality of $\mathbb{V}(\mathfrak{p})$.

□

Proof of (8.94):

- Let us begin by proving that $I \mapsto \overline{I}$ is well-defined: As $I \subseteq U$ is non-empty, we have $\emptyset \neq I = I \cap U \subseteq \overline{I} \cap U$ and therefore $\overline{I} \cap U \neq \emptyset$. Also $\overline{I} \subseteq X$ is closed and (as I is irreducible) irreducible, by property (b) in (8.91.(i)).

 Next we will see, that $J \mapsto J \cap U$ is well-defined, too: $J \cap U \neq \emptyset$ is non-empty, by assumption. And as $J \subseteq X$ is closed, so is $J \cap U \subseteq U$ in the relative topology. It remains to prove, that $J \cap U$ is irreducible again: Consider any open non-empty subsets $P, Q \subseteq J \cap U$. That is $P = P' \cap (J \cap U)$ and $Q = Q' \cap (J \cap U)$ for some open subsets $P', Q' \subseteq X$. As $U \subseteq X$ is open, we see that P and Q are an open subset of J, e.g. for P we have

 $$P \;=\; P' \cap (J \cap U) \;=\; (P' \cap U) \cap J$$

 But as J is irreducible and P, Q are non-empty, open subsets of J we get $P \cap Q \neq \emptyset$. As this is true for any non-empty, open subsets of $J \cap U$, this means $J \cap U$ is irreducible again.

- The next step is proving that these maps are mutually inverse: We begin by arguing for $\overline{I} \cap U = I$: As $I \subseteq U$ the inclusion $I \subseteq \overline{I} \cap U$ is clear. Conversely, as $I \subseteq U$ is closed, it is of the form $I = I' \cap U$ for some $I' \subseteq X$ closed. As $I \subseteq I'$ we have $\overline{I} \subseteq I'$ and thereby $\overline{I} \cap U \subseteq I' \cap U = I$.

Now for $\overline{J \cap U} = J$, but this is easy: As $J \cap U \subseteq J$ is non-empty and open and J is irreducible, $J \cap U$ is dense in J, by property (c) of (8.90.(i)) and this already is $\overline{J \cap U} = J$.

- The correspondence of the irreducible components is straightforward: If we start with $I \in \mathrm{IRR}(U)$, then we have to show, that $\overline{I} \in \mathrm{IRR}(X)$. So suppose $\overline{I} \subseteq J$, then $I = \overline{I} \cap U \subseteq J \cap U$ and thereby $I = J \cap U$, as I is maximal. Then again $\overline{I} = \overline{J \cap U} = J$, which is the maximality of $\overline{I}$.

 Conversely, for $J \in \mathrm{IRR}(X)$ we have to show $J \cap U \in \mathrm{IRR}(U)$. Hence we consider $J \cap U \subseteq I$ for some irreducible $I \subseteq U$. Then $J = \overline{J \cap U} \subseteq \overline{I}$ and thereby $J = \overline{I}$, as J is maximal. Then again $J \cap U = \overline{I} \cap U = I$, which is the maximality of $J \cap U$.

- It remains to show the correspondence of generic points: For any $x \in U$ let us denote the closure of $\{ x \}$ in U by $I_x := \mathrm{cl}_U(\{ x \})$ and the closure in X by $J_x := \mathrm{cl}_X(\{ x \})$. Then by (6.16.(x)) we have $I_x = J_x \cap U$. So if we start with $J \cap U = I_x$, then I_x corresponds to J_x and thereby $J = J_x$. Conversely, if we start with $J = J_x$ we still have to prove $x \in U$. Suppose we had $x \notin U$, then $x \in J \setminus U$ which is a closed subset of J. In particular $J = J_x \subseteq J \setminus U$ and thereby $J \cap U = \emptyset$, which was assumed to be not the case. So we have $x \in U$ and thereby $J \cap U = J_x \cap U = I_x$ again.

□

Proof of (8.96):

(i) Let us first consider the case of a closed subset $C \subseteq X$: If $I_0 \subset \ldots \subset I_d \subseteq C$ is any chain of closed, irreducible subsets of C, then as $C \subseteq X$ is closed, any $I_k \subseteq C$ also is a closed subset $C \subseteq X$. Thus $I_0 \subset \ldots \subset I_d \subseteq X$ also is a chain of closed, irreducible subsets of X and therefore $\mathrm{tdim}(C) \leq \mathrm{tdim}(X)$.

(i) Let us now consider the case of an open subset $U \subseteq X$: If $I_0 \subset \ldots \subset I_d \subseteq C$ is any chain of closed, irreducible subsets of U, then by (8.94) this corresponds to a chain $\overline{I}_0 \subseteq \ldots \subseteq \overline{I}_d \subseteq X$ of closed, irreducible subsets of X. Suppose there was some $k \in 1 \ldots d$ such that $\overline{I}_{k-1} = \overline{I}_k$, then we had $I_{k-1} = \overline{I}_{k-1} \cap U = \overline{I}_k \cap U = I_k$, which is false. Thus $\overline{I}_0 \subset \ldots \subset \overline{I}_d \subseteq X$ is strictly increasing and thereby $d \leq \mathrm{tdim}(X)$. As this is true for any chain in U, we conclude $\mathrm{tdim}(U) \leq \mathrm{tdim}(X)$.

(ii) Since X is finite-dimensional, so is C by (i). The we may consider $I_0 \subset \ldots \subset I_d \subseteq C$ with $d = \mathrm{tdim}(C)$. As $C \subset X$ and X is irreducible, this chain may be appended, to $I_0 \subset \ldots \subset I_d \subset X$ and hence $\mathrm{tdim}(X) \geq d + 1 > d = \mathrm{tdim}(C)$.

(iii) If $I \in \mathrm{IRR}(X)$ is an irreducible component, then $I \subseteq X$ is closed and hence $\mathrm{tdim}(I) \leq \mathrm{tdim}(X)$ due to (i). This proves the first estimate $m := \max\{ \mathrm{tdim}(I) \mid I \in \mathrm{IRR}(X) \} \leq d := \mathrm{tdim}(X)$. Conversely consider a chain of maximal length $I_0 \subset \ldots \subset I_d \subseteq X$ in X. Then I_d has to maximal and hence $I_d \in \mathrm{IRR}(X)$. Thus we also get $d \leq \mathrm{tdim}(I_d) \leq m$.

□

Proof of (8.97):

- (a) $\implies$ (d): Let $U := \bigcup_{i \in \mathbb{N}} U_i$. Then by assumption U admits a finite subcover, that is there is a finite set $\Omega \subseteq \mathbb{N}$ such that $U = \bigcup_{i \in \Omega} U_i$. Now let $n := \max(\Omega) \in \mathbb{N}$ be the maximal number contained in Ω, then for any $i \in \Omega$ we have $U_i \subseteq U_n$, as the U_i form an ascending chain. Hence for any $k \in \mathbb{N}$ we get the inclusions $U_{n+k} \subseteq U = \bigcup_{i \in \Omega} U_i = U_n \subseteq U_{n+k}$.

- (d) $\Longrightarrow$ (a): Consider $U = \bigcup_{i\in I} U_i$, if I is finite, then there is nothing to prove, thus we may assume I to be infinite. As $U_i \subseteq U$ and $U \subseteq X$ are open, $U_i \subseteq X$ is open, too. Now choose any $i(0) \in I$ and let $V_0 := U_{i(0)}$. Suppose we have already constructed $V_k \subseteq U$ and that $U \neq V_k$. Then there is some $x \in U \setminus V_k$ and hence some $i(k+1) \in I$ such that $x \in U_{i(k+1)}$. Now let $V_{k+1} := V_k \cup U_{i(k+1)} = U_{i(0)} \cup \cdots \cup U_{i(k)} \cup U_{i(k+1)}$. Then we found a strictly ascending chain

$$V_0 \subset \ldots \subset V_k \subset V_{k+1}$$

 Due to (d) this cannot rise indefinitely, which means that there has to be some index $n \in \mathbb{N}$ at which $U = V_n = U_{i(0)} \cup \cdots \cup U_{i(n)}$. That is we have found a finite subcover of U.

- (d) $\Longrightarrow$ (b): Let $\mathcal{U} := \{ U_i \mid i \in I \}$ for some index set I and suppose $\mathcal{U}$ had no maximal element. We begin with any $i(0) \in I$. Now suppose we have already chosen $i(0), \ldots, i(k) \in I$ in such a way that $U_{i(0)} \subset \ldots \subset U_{i(k)}$, then we continue: As $\mathcal{U}$ does not have a maximal element, $U_{i(k)}$ is not maximal and this means there is some $i(k+1) \in I$ such that $U_{i(k)} \subset U_{i(k+1)}$. That is we can always append the chain in such a way, that $U_{i(0)} \subset \ldots \subset U_{i(k)} \subset U_{i(k+1)}$. Thereby we obtain a strictly ascending chain of open sets, that does not become stationary, in contradiction to (d). This contradiction yields, that $\mathcal{U}$ *has* a maximal element.

- (b) $\Longrightarrow$ (d): Consider $\mathcal{U} := \{ U_i \mid i \in \mathbb{N} \}$, by assumption (b) $\mathcal{U}$ has a maximal element $U^* = U_n$ for some $n \in \mathbb{N}$. But for any $k \in \mathbb{N}$ we also have $U_n \subseteq U_{n+k}$ as the U_i form an ascending chain. Thus $U_n = U_{n+k}$ by maximality of U_n.

- Thus we have obtained the equivalences (a) $\Longleftrightarrow$ (b) $\Longleftrightarrow$ (d). But by going to complements the equivalences (b) $\Longleftrightarrow$ (c) and (d) $\Longleftrightarrow$ (e) are obvious.

□

Proof of (8.98):

(i) This is just a side-effect of the Laskar-Noether theorem, that will be proved right after this proposition (and not be used before, of course). The reader is asked to refer to (8.99).

(iv) Let us first assume that $L = C \subseteq X$ is a closed subset. If now $C_1 \supseteq C_2 \supseteq \ldots$ is a descending chain of closed subsets $C_i \subseteq C$, then clearly $C_i \subseteq X$ is closed, too. And as X was assumed to be noetherian the chain has to stabilize, which proves, that C is noetherian, too.

(iii) Let $L = C \cap U$, where $C \subseteq X$ is closed and $U \subseteq X$ is open, we will prove, that L is compact. To do this consider any cover $L = \bigcup_i U_i$ (where $i \in I$) by open sets $U_i \subseteq L$. By definition of the relative topology there are open subsets $U_i' \subseteq X$ such that $U_i = U_i' \cap L$. And if we let $V_i := U \cap U_i'$, then $V_i \subseteq X$ is open and we get $U_i = U_i' \cap L = C \cap V_i$. Hence we have

$$C \cap U = L = \bigcup_{i\in I} U_i = \bigcup_{i\in I} C \cap V_i$$

That is the open subset $C \cap U \subseteq C$ is covered by the open sets $C \cap V_i \subseteq C$. But (iv) above (for closed sets) C is noetherian and hence $C \cap U$ is compact, by property (a) of (8.97). That is there

is some finite subset $\Omega \subseteq I$ such that

$$L \;=\; C \cap U \;=\; \bigcup_{i\in\Omega} C \cap V_i \;=\; \bigcup_{i\in\Omega} U_i$$

(iv) Let us now prove the claim for general locally closed subsets $L \subseteq X$, say $L = C \cap U$ again. Consider an open subset $K \subseteq L$, that is $K = V \cap L$ for some $V \subseteq X$ open and hence we find, that $K = V \cap L = C \cap (U \cap V)$ is a locally closed subset $K \subseteq X$ again. Thus it is compact, due to (iii) above. That is any open subset of L is compact, which means that L satisfies property (a) of (8.97) and hence is a noetherian topological space.

(v) Consider the set $\mathcal{F} := \{\, C \subseteq X \text{ closed} \mid \varphi(C) = \text{ false} \,\}$. If $\mathcal{F} \neq \emptyset$ then $\mathcal{F}$ has a minimal element $F \in \mathcal{F}$, since X is noetherian. As $\varphi(\emptyset)$ is true, we have $F \neq \emptyset$. And if $C \subseteq X$ is closed with $C \subset F$, then $\varphi(C)$ has to be true, by the minimality of F. Thus by assumption we also get $\varphi(F) = $ true, a contradiction. Therefore $\mathcal{F} = \emptyset$ and this means $\varphi(C)$ is true for any closed subset $C \subseteq X$, in particular for $C = X$.

□

Proof of (8.99):
Existence: Let us denote $\mathcal{E} := \{\, X \subseteq N \text{ closed} \mid \text{existence not satisfied} \,\}$. That is $\mathcal{E}$ is a collection of closed subsets of N. If $\mathcal{E}$ was non-empty, then there was a minimal subset $X \in \mathcal{E}$ (as N is noetherian). In particular X is reducible (else the existence was satisfied trivially). That is $X = C \cup D$ for some closed subsets $C, D \subseteq X$ with $C, D \neq X$. As X has been minimal we get $C, D \notin \mathcal{E}$. Yet C and D are closed in X and hence in N, which means that C and D have to allow the existence. That is

$$\begin{aligned} C &= C_1 \cup \cdots \cup C_r \\ D &= D_1 \cup \cdots \cup D_s \end{aligned}$$

From this we get $X = C \cup D = C_1 \cup \cdots \cup C_r \cup D_1 \cup \cdots \cup D_s$. In this representation the properties (1), (3) and (4) are satisfied trivially. And by scratching the redundant C_i and D_j we may also guarantee property (2). Thus X also allows the existence and hence $X \notin \mathcal{E}$, a contradiction. This only leaves $\mathcal{E} = \emptyset$, that is any closed subset X of N allows a decomposition satisfying (1) to (4).

Uniqueness: Suppose $X_1 \cup \cdots \cup X_r = X = Y_1 \cup \cdots \cup Y_s$ such that the X_i and Y_i satisfy the properties (1) to (3). As $X_i \subseteq X$ we have $X_i = X_i \cap X$ and as $X = \bigcup_j Y_j$ this implies

$$X_i \;=\; \bigcup_{j=1}^{s} X_i \cap Y_j$$

As Y_j is closed in X it is closed in N and hence $X_i \cap Y_j$ is closed in X_i. As X_i is irreducible this implies that there is some $j \in 1 \ldots s$ such that $X_i = X_i \cap Y_j$. That is $X_i \subseteq Y_j$. In complete analogy to the above we find some $k \in 1 \ldots r$ such that $Y_j \subseteq X_k$. Hence $X_i \subseteq Y_j \subseteq X_k$. By property (2) this implies $i = k$ and hence $X_i = Y_j$. Now let $\sigma(i) := j$ and use this construction for any $i \in 1 \ldots r$, then $\sigma : 1 \ldots r \to 1 \ldots s$ is a mapping. And if $\sigma(i) = \sigma(j)$ then $X_i = Y_{\sigma(i)} = Y_{\sigma(j)} = X_j$ such that $i = j$ due to property (2). That is σ is injective and hence $r \leq s$. Exchanging the roles of the X_i and Y_j we also find

$s \leq r$ and hence $r = s$. That is σ is a permutation and this is the uniqueness.

Property (5): As N is a noetherian topological space, so is X, according to (8.98.(iv)). And hence X has only finitely many irreducible components, as we have seen in (8.98.(i)). Now let $\mathcal{I} := \{ X_1, \ldots, X_r \}$ and take a look at the second part of (8.93). Property (1) there is property (1) here. Property (2) there are properties (3) and (4) here and we also get property (3) there: For ease of notation we prove $X \neq X_2 \cup \cdots \cup X_r$ only: Suppose $X_1 \subseteq X = X_2 \cup \cdots \cup X_r$, as X_1 is irreducible and any X_i (for $i \in 2 \ldots r$) is closed we have $X_1 \subseteq X_k$ for some $k \in 2 \ldots r$, which is forbidden by property (2) here. Thus we also have property (3) of (8.93) and conclude $\mathcal{I} = \operatorname{IRR}(X)$. □

Proof of (8.100):
Let us first assume that $X = \{ x_1, \ldots, x_r \}$ is finite and denote $X_i := \{ x_i \}$, then we have to show that $\operatorname{tdim}(X) = 0$. It is clear that any X_i is irreducible and as X is T_1 the $X_i \subseteq X$ are closed, too. And by construction we also have $X = X_1 \cup \cdots \cup X_r$ and $X_i \not\subseteq X_j$ for any $i \neq j \in 1 \ldots r$. Altogether the X_i satisfy properties (1) to (4) in (8.99) and hence we get $\operatorname{IRR}(X) = \{ X_1, \ldots, X_r \}$. Now suppose that $I_0 \subset I_1 \subset \ldots \subset I_d$ is a chain of closed, irreducible subsets of X, such that I_0 is non-empty. As $I_0 \neq \emptyset$ there is some $x_i \in I_0$ and hence $X_i \subseteq I_k$ (for any $k \in 0 \ldots d$). As X_i is maximal (an irreducible component) we get $X_i = I_0 = I_1 = \cdots = I_d$ and hence $d = 0$. In particular $\operatorname{tdim}(X) = 0$ which had to be shown.
Conversely assume that $\operatorname{tdim}(X) = 0$, then we need to show that X is finite. Thus consider any point $x \in X$ and any irreducible set $I \subseteq X$ with $\{ x \} \subseteq I$. As I is irreducible, so is $\overline{I}$, due to (8.91.(i)). And as X has been assumed to T_1 we know that $\{ x \} \subseteq X$ is closed, such that $\{ x \} \subseteq \overline{I}$ is a chain of closed, irreducible subsets. Yet as $\operatorname{tdim}(X) = 0$ this implies $I \subseteq \overline{I} = \{ x \} \subseteq I$ and hence $I = \{ x \}$. That is $\{ x \}$ is maximal, in other words an irreducible component of X. But by (8.98.(i)) X only has finitely many irreducible components. In particular we get $\#X = \#\operatorname{IRR}(X) < \infty$ as claimed. □

Proof of (8.103):
If $X = \emptyset$, there is nothing to prove, as $\operatorname{IRR}(X) = \{ \emptyset \} = \operatorname{CNC}(X)$. Thus assume $X \neq \emptyset$ and let us denote the irreducible components by $\operatorname{IRR}(X) = \{ I_1, \ldots, I_s \}$, thereby s is finite, due to (8.98.(i)). Any irreducible subset $I \subseteq X$ already is connected by (8.91.(iii)). And as any $I_j \neq \emptyset$ is non-empty and connected proposition (6.37.(ii)) implies that there is a uniquely determined connected component $K \in \operatorname{CNC}(X)$ such that $I_j \subseteq K$. Thus let $\{ K_1, \ldots, K_r \} \subseteq \operatorname{CNC}(X)$ be a collection of connected components of X such that

$$\forall\, j \in 1 \ldots s \;\; \exists\, i \in 1 \ldots r \;\; : \;\; I_j \subseteq K_i$$

By removing duplicates, we can take the K_i to be are pairwise distinct, that is $K_h = K_i$ implies $i = h$. For any $i \in 1 \ldots r$ let us now denote $J(i) := \{ j \in 1 \ldots s \mid I_j \subseteq K_i \}$. Suppose we had $j \in J(h) \cap J(i)$ then $I_j \subseteq K_h \cap K_i$. However, by construction, distinct connected components are disjoint and as $I_j \neq \emptyset$ we hence conclude $K_h = K_i$. As we have taken the K_i to be pairwise distinct, this implies $h = i$. That is the $J(i)$ are pairwise disjoint and hence we have partitioned $1 \ldots s$ into $(1 \ldots s) = J(1) \cup \cdots \cup J(r)$. Altogether we have

$$X \;=\; \bigcup_{j=1}^{s} I_j \;=\; \bigcup_{i=1}^{r} \bigcup_{j \in J(i)} I_j \;\subseteq\; \bigcup_{i=1}^{r} K_i \;\subseteq\; X$$

That is $X = \bigcup_i K_i$. Now consider any *any* connected component $L \in \operatorname{CNC}(X)$. As $L \neq \emptyset$ (by maximality)

we may choose some $x \in L \subseteq X$. Thus there is some $i \in 1 \dots r$ such that $x \in K_i$. For this i we get $L \cap K_i \neq \emptyset$. And as distinct connected components would be disjoint, this implies $L = K_i$. Thus we have also obtained $\mathrm{CNC}(X) \subseteq \{ K_1 \dots, K_r \}$. By construction the map $(1 \dots s) \twoheadrightarrow (1 \dots r) : j \mapsto i$ such that $I_j \subseteq K_i$ is surjective and hence

$$\#\mathrm{CNC}(X) \;=\; r \;\leq\; s \;=\; \#\mathrm{IRR}(X)$$

In particular X has only finitely may connected components and hence (6.37.(iv)) yields a partition of X into the topological sum $X = K_1 \oplus \dots \oplus K_r$. In particular any K_i is both, open and closed. Next we will prove the following implication for any $j \in 1 \dots s$ and any $i \in 1 \dots r$

$$I_j \cap K_i \neq \emptyset \quad\Longrightarrow\quad I_j \subseteq K_i$$

First of all $I_j \cap K_i \subseteq I_j$ is open and closed, as $K_i \subseteq X$ is open and closed. But as I_j is irreducible any non-empty open subset is dense, in particular $I_j \cap K_i \subseteq I_j$ is dense. But as $I_j \subseteq K_i \subseteq I_j$ also is closed we get $I_j \cap K_i = I_j$, which translates into $I_j \subseteq K_i$. As $(1 \dots s) = I(1) \cup \dots \cup I(r)$ and $I(j) = \mathcal{I}(K_j)$ by construction this translates into the the first identity of $\mathrm{IRR}(X)$ in the claim. It remains to verify that the second identity for K, which reads as (for any $i \in 1 \dots r$)

$$K_i \;=\; \bigcup_{j \in J(i)} I_j$$

By definition of $J(i)$ we have $I_j \subseteq K_i$ for any $j \in J(i)$. And this implies " $\supseteq$ ". Conversely consider any $x \in K_i \subseteq X = I_1 \cup \dots \cup I_s$, then there is some $j \in 1 \dots s$ such that $x \in I_j$. For this j we now have $x \in I_j \cap K_i$ and hence $I_j \subseteq K_i$ by the above implication. Thus we have found $x \in I_j$ for some $j \in J(i)$ and as this is true for any $x \in K_i$, this also grants the inclusion " $\subseteq$ ". □

Proof of (8.104):
We start with (a) $\Longrightarrow$ (b), that is $\mathfrak{m} = Rm_1 + \dots + Rm_n$ is generated as an R-module. Then it is clear that $\{m_i + \mathfrak{m}^2 \mid i \in 1 \dots n\}$ is a generating set of $\mathfrak{m}/\mathfrak{m}^2$: Given any $x + \mathfrak{m}^2 \in \mathfrak{m}/\mathfrak{m}^2$ we may choose $a_1, \dots, a_n \in R$ such that $x = a_1 m_1 + \dots + a_n m_n$ and thereby $x + \mathfrak{m}^2 = \sum_i a_i m_i + \mathfrak{m}^2 = \sum_i (a_i + \mathfrak{m})(m_i + \mathfrak{m}^2)$. As R is noetherian $\mathfrak{m}$ is finitely generated. Hence we may choose a generating set with a minimal number generators and for this we find

$$\dim_E \left(\mathfrak{m} \Big/ \mathfrak{m}^2 \right) \;\leq\; \#\left\{ m_i + \mathfrak{m}^2 \mid i \in 1 \dots n \right\} \;\leq\; n \;=\; \mathrm{rank}_R(\mathfrak{m})$$

Conversely for (b) $\Longrightarrow$ (a), we start with a set $\{m_i + \mathfrak{m}^2 \mid i \in 1 \dots n\}$ that generates $\mathfrak{m}/\mathfrak{m}^2$ as an E-vector-space. Then we let $\mathfrak{a} := Rm_1 + \dots + Rm_n \trianglelefteq_{\mathfrak{i}} R$. We will now prove, that

$$\mathfrak{m} \;=\; \mathfrak{a} + \mathfrak{m}^2$$

As any $m_i \in \mathfrak{m}$ we also have $\mathfrak{a} \subseteq \mathfrak{m}$ and $\mathfrak{m}^2 \subseteq \mathfrak{m}$ is clear such that $\mathfrak{a} + \mathfrak{m}^2 \subseteq \mathfrak{m}$ and we have the inclusion " $\supseteq$ ". Conversely if we are given any $x \in \mathfrak{m}$ then we may choose $a_i + \mathfrak{m} \in E$ such that $x + \mathfrak{m}^2 = \sum_i (a_i + \mathfrak{m})(m_i + \mathfrak{m}^2) = (\sum_i a_i m_i) + \mathfrak{m}^2$. Hence we have $d := x - \sum_i a_i m_i \in \mathfrak{m}^2$. Thereby $a := \sum_i a_i m_i \in \mathfrak{a}$ by construction, such that $x = a + d \in \mathfrak{a} + \mathfrak{m}^2$. This is the converse inclusion " $\subseteq$ "
Now remark that $\mathrm{JAC}(R) = \mathfrak{m}$, as R is a local ring. Furthermore we have $\mathfrak{m}^2 = \mathfrak{m}\,\mathfrak{m}$ and $\mathfrak{m}$ is a

finitely generated R-module, as R is noetherian. Thus by the lemma of Nakayama (3.44.(iii)) [using the parameters $P := \mathfrak{a}$, $M := \mathfrak{m}$ and $\mathfrak{a} := \mathfrak{m}$] we find $\mathfrak{m} = \mathfrak{a}$. That is $\{ m_1, \ldots, m_n \}$ generates $\mathfrak{m}$. If we start with a basis $m_i + \mathfrak{m}^2$ of $\mathfrak{m}/\mathfrak{m}^2$ we in particular find, that

$$\operatorname{rank}_R(\mathfrak{m}) \;\leq\; n \;=\; \dim_E \left(\mathfrak{m} \Big/ \mathfrak{m}^2 \right)$$

□

Proof of (8.106):
If $\mathfrak{p} = \mathfrak{m}$, then $\operatorname{height}(\mathfrak{p}) = \operatorname{height}(\mathfrak{m})$ is clear. Conversely suppose $\operatorname{height}(\mathfrak{p}) = \operatorname{height}(\mathfrak{m})$ and pick up a CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$ of R, with $\mathfrak{p}_r = \mathfrak{p}$ and $r = \operatorname{height}(\mathfrak{p})$. Now $\mathfrak{p}_r$ is contained in a maximal ideal by (2.4.(ii)). And as R is local there is only one maximal ideal around: $\mathfrak{p}_r \subseteq \mathfrak{m}$. Suppose we had $\mathfrak{p}_r \subset \mathfrak{m}$, then $(\mathfrak{p}_0, \ldots, \mathfrak{p}_r, \mathfrak{m})$ would be a CPI, too and hence $\operatorname{height}(\mathfrak{m}) \geq r+1$, in contradiction to $\operatorname{height}(\mathfrak{m}) = r$. Thus we have the identity $\mathfrak{p} = \mathfrak{p}_r = \mathfrak{m}$, as claimed. □

Proof of (8.107):
Clearly for any ideal $\mathfrak{m}$ of R we have $\operatorname{height}(\mathfrak{m}) \leq \operatorname{kdim}(R)$. Conversely consider $(\mathfrak{p}_0, \ldots, \mathfrak{p}_d)$ any CPI of R. If $\mathfrak{p}_d$ is not maximal itself, then it is contained in a maximal ideal by (2.4.(ii)) and we may append this chain. Therefore we may assume $\mathfrak{p}_d$ to be a maximal ideal. As R is a local ring there is one choice only: $\mathfrak{p}_d = \mathfrak{m}$. Therefore $d \leq \operatorname{height}(\mathfrak{m})$ and as this is true for any CPI, we conclude $\operatorname{kdim}(R) \leq \operatorname{height}(\mathfrak{m})$, too. That is $\operatorname{kdim}(R) = \operatorname{height}(\mathfrak{m})$ and by Krull's height theorem (8.80.(iii)) - recall that R also is assumed to be noetherian - we have $\operatorname{height}(\mathfrak{m}) < \operatorname{rank}(\mathfrak{m}) < \infty$.

Let n be the minimal number of elements $a_1, \ldots, a_n \in R$ such that $\mathfrak{m}$ is a minimal prime ideal over $\mathfrak{a} := \langle a_1, \ldots, a_n \rangle_{\mathfrak{i}}$. Then by Krull's height theorem (8.80.(ii)) we have $\operatorname{height}(\mathfrak{m}) \leq n$ and thereby $\operatorname{kdim}(R) \leq n$. Conversely if $d = \operatorname{kdim}(R) = \operatorname{height}(\mathfrak{m})$ then by the reverse direction in (8.80.(ii)) there are some $a_1, \ldots, a_d \in R$ such that $\mathfrak{m}$ is a minimal prime ideal over $\langle a_1, \ldots, a_d \rangle_{\mathfrak{i}}$. As n is the minimal number for which this is possible we also have $n \leq d = \operatorname{kdim}(R)$. □

Proof of (8.109):

(i) Let us abbreviate $\overline{R} := R/\mathfrak{a}$ and for any $b \in R$ also $\overline{b} := b + \mathfrak{a}$. As R is noetherian, so is $\overline{R}$, as any chain of ideals in $\overline{R}$ originates from a chain of ideals in R. Also R is a local ring with maximal ideal $\overline{\mathfrak{m}} := \mathfrak{m}/\mathfrak{a}$ by the correspondence theorem (1.71). Let $n := \operatorname{kdim}(\overline{R})$, which is finite, by (8.107). Then we may pick up a local system of parameters $\left\{ \overline{b}_1, \ldots, \overline{b}_n \right\}$ of $\overline{R}$. That is $\overline{\mathfrak{m}}$ is a prime ideal, minimal over $\overline{\mathfrak{b}} := \langle \overline{b}_1, \ldots, \overline{b}_n \rangle_{\mathfrak{i}}$. We will prove that $\mathfrak{m}$ is a minimal prime ideal over $\mathfrak{a} + \mathfrak{b}$, as well: To do this consider any prime ideal $\mathfrak{p} \in \operatorname{Spec}(R)$ in between $\mathfrak{a} + \mathfrak{b} \subseteq \mathfrak{p} \subseteq \mathfrak{m}$. By going to quotients $/\mathfrak{a}$ this chain turns into

$$\overline{\mathfrak{b}} \;=\; \langle \overline{b}_1, \ldots, \overline{b}_n \rangle_{\mathfrak{i}} \;=\; \mathfrak{a} + \mathfrak{b} \Big/ \mathfrak{a} \;\subseteq\; \mathfrak{p} \Big/ \mathfrak{a} \;\subseteq\; \mathfrak{m} \Big/ \mathfrak{a} \;=\; \overline{\mathfrak{m}}$$

But $\overline{\mathfrak{m}}$ is a minimal prime ideal over $\overline{\mathfrak{b}}$ such that we get $\overline{\mathfrak{p}} = \overline{\mathfrak{m}}$ and from this we get $\mathfrak{p} = \mathfrak{m}$ by correspondence (as $\mathfrak{a} \subseteq \mathfrak{p}$, as well). Thus $\mathfrak{m}$ is a minimal prime ideal over $\mathfrak{a} + \mathfrak{b}$ and therefore Krull's height theorem (8.80.(ii)) tells us $\operatorname{kdim}(R) = \operatorname{height}(\mathfrak{m}) \leq m + n = m + \operatorname{kdim}(\overline{R})$. In other words, we have found the claim $\operatorname{kdim}(R) - m \leq \operatorname{kdim}(\overline{R})$.

(ii) Let $\mathfrak{b} := \langle a_{m+1}, \ldots, a_n \rangle_{\mathfrak{i}}$, that is $\mathfrak{a} + \mathfrak{b} = \langle a_1, \ldots, a_n \rangle_{\mathfrak{i}}$. Then by assumption we have $n = \operatorname{kdim}(R)$

and $\mathfrak{m}$ is a prime ideal, minimal over $\mathfrak{a}+\mathfrak{b}$. As in the proof of (i) let us abbreviate $\overline{R} := R/\mathfrak{a}$, $\overline{a}_i := a_i + \mathfrak{a}_i$ and $\overline{\mathfrak{m}} := \mathfrak{m}/\mathfrak{a}$. Then the residue of $\mathfrak{a}+\mathfrak{b}$ in $\overline{R}$ is $\overline{\mathfrak{b}} = \langle \overline{a}_{m+1}, \ldots, \overline{a}_n \rangle_{\mathfrak{i}}$. Let us now prove, that $\overline{\mathfrak{m}}$ is a prime ideal minimal over $\overline{\mathfrak{b}}$. That is we consider any prime ideal $\overline{\mathfrak{p}}$ in between $\overline{\mathfrak{b}} \subseteq \overline{\mathfrak{p}} \subseteq \overline{\mathfrak{m}}$. That is $\overline{\mathfrak{p}} = \mathfrak{p}/\mathfrak{a}$ for some $\mathfrak{p} \in \operatorname{Spec}(R)$ with $\mathfrak{a} \subseteq \mathfrak{p}$. By assumption we have $a_k \in \mathfrak{p}$ for any $k \in m+1 \ldots n$ and therefore $\mathfrak{b} \subseteq \mathfrak{p}$. Together this is $\mathfrak{a}+\mathfrak{b} \subseteq \mathfrak{p} \subseteq \mathfrak{m}$ and thereby $\mathfrak{p} = \mathfrak{m}$, as $\mathfrak{m}$ is a prime ideal minimal over $\mathfrak{a}+\mathfrak{b}$. But from this we find $\overline{\mathfrak{p}} = \overline{\mathfrak{m}}$ and hence $\overline{\mathfrak{m}}$ is a prime ideal of $\overline{R}$, minimal over $\overline{\mathfrak{b}}$.

(iii) Suppose $\operatorname{kdim}(R/\mathfrak{a}) = \operatorname{kdim}(R) - m$ and let $n := \operatorname{kdim}(R)$. As $\overline{R} := R/\mathfrak{a}$ is a noetherian, local ring by (i), we find a local system of parameters $\left\{ \overline{b}_1, \ldots, \overline{b}_s \right\}$ of $\overline{R}$. In particular $\overline{\mathfrak{m}} = \mathfrak{m}/\mathfrak{a}$ is a prime ideal minimal over $\overline{\mathfrak{b}} := \langle \overline{b}_1, \ldots, \overline{b}_s \rangle_{\mathfrak{i}}$ and we have $s = \operatorname{kdim}(\overline{R}) = n - m$. Therefore $\{ a_1, \ldots, a_m, b_1, \ldots, b_s \}$ contains $n = \operatorname{kdim}(R)$ many elements. Now let $\mathfrak{b} := \langle b_1, \ldots, b_s \rangle_{\mathfrak{i}}$ and consider any prime ideal $\mathfrak{p} \in \operatorname{Spec}(R)$ such that $\mathfrak{a}+\mathfrak{b} \subseteq \mathfrak{p} \subseteq \mathfrak{m}$. As in (i) above we find $\overline{\mathfrak{p}} \subseteq \overline{\mathfrak{m}}$ and hence $\mathfrak{p} = \mathfrak{m}$, as $\mathfrak{a} \subseteq \mathfrak{p}$, too. Thus $\mathfrak{m}$ is a prime ideal minimal over $\mathfrak{a}+\mathfrak{b} = \langle a_1, \ldots, a_m, b_1, \ldots, b_s \rangle_{\mathfrak{i}}$ and therefore $\{ a_1, \ldots, a_m, b_1, \ldots, b_s \}$ is a local set of parameters of R. That is we have been able to append $\{ a_1, \ldots, a_m \}$.

(iii) Suppose we can append $\{ a_1, \ldots, a_m \}$ to a local system of parameters, $\{ a_1, \ldots, a_n \}$ of R, then by (ii) $\mathfrak{m}/\mathfrak{a}$ is a prime ideal minimal over $\langle a_{m+1}, \ldots, a_n \rangle_{\mathfrak{i}}$. Hence by Krull's height theorem (8.80.(ii)) we have $\operatorname{height}(\mathfrak{m}/\mathfrak{a}) \leq n - m$. But this is

$$\operatorname{kdim}\left(R \Big/ \mathfrak{a}\right) \;=\; \operatorname{height}\left(\mathfrak{m} \Big/ \mathfrak{a}\right) \;\leq\; n - m \;=\; \operatorname{kdim}(R) - m$$

But we also have $\operatorname{kdim}(R/\mathfrak{a}) \geq \operatorname{kdim}(R) - m$ by (i), so together this can be combined to the equality $\operatorname{kdim}(R/\mathfrak{a}) \geq \operatorname{kdim}(R) - m$.

(iv) We use theorem (8.80.(v)): As $m = \operatorname{height}(\mathfrak{a}) \leq \operatorname{kdim}(R) = \operatorname{height}(\mathfrak{m}) =: n$ we can append elements $a_{m+1}, \ldots, a_n \in \mathfrak{m}$ such that for any $k \in m \ldots n$ we get: Let $\mathfrak{a}_k := \langle a_1, \ldots, a_k \rangle_{\mathfrak{i}}$ and $\mathfrak{p}_k$ be a prime ideal minimal over $\mathfrak{a}_k$, then we get $\operatorname{height}(\mathfrak{p}_k) = k$. In particular $\operatorname{height}(\mathfrak{p}_n) = n = \operatorname{height}(\mathfrak{m})$. But $\mathfrak{m}$ is the one and only ideal in R of height n, by (8.106), such that we conclude $\mathfrak{p}_n = \mathfrak{m}$. That is $\mathfrak{m}$ is a prime ideal, minimal over $\langle a_1, \ldots, a_n \rangle_{\mathfrak{i}}$ and $n = \operatorname{height}(\mathfrak{m}) = \operatorname{kdim}(R)$. In other words $\{ a_1, \ldots, a_n \}$ is a system of local parameters of R - we have been able, to append $\{ a_1, \ldots, a_m \}$, which is part (1) of the claim. Now by (iii) we have $\operatorname{kdim}(R/\mathfrak{a}) = \operatorname{kdim}(R) - m = \operatorname{kdim}(R) - \operatorname{height}(\mathfrak{a})$, which already is (3). Also we know by (ii), that $\mathfrak{m}/\mathfrak{a}$ is a prime ideal, minimal over $\langle a_{m+1} + \mathfrak{a}, \ldots, a_n + \mathfrak{a} \rangle_{\mathfrak{i}}$. But by (3) we have just seen $\operatorname{kdim}(R/\mathfrak{a}) = \operatorname{kdim}(R) - m = n - m$, which makes $\{ a_{m+1} + \mathfrak{a}, \ldots, a_n + \mathfrak{a} \}$ a local system of parameters for $R/\mathfrak{a}$.

□

15.10 Proofs of Chapter 11

Proof of (11.10):

(ii) We start with (b) $\Longrightarrow$ (a): Choose $T := X$, then $\varphi^* : \mathcal{C}(Y,X) \twoheadrightarrow \mathcal{C}(X,X)$ is surjective, by assumption. As $\mathbb{1}_X \in \mathcal{C}(X,X)$ there is some $\overline{\varphi} \in \mathcal{C}(Y,X)$ such that $\overline{\varphi} \circ \varphi = \varphi^*(\overline{\varphi}) = \mathbb{1}_X$ and this is (a). Conversely suppose (a), that is $\overline{\varphi} \circ \varphi = \mathbb{1}_X$. Then we regard the chain

$$\mathcal{C}(X,T) \xrightarrow{\overline{\varphi}^*} \mathcal{C}(Y,T) \xrightarrow{\varphi^*} \mathcal{C}(X,T)$$

Starting with any $\tau \in \mathcal{C}(X,T)$, this is mapped to $\tau \mapsto \overline{\varphi}^*(\tau) = \tau \circ \overline{\varphi}$ which in turn is mapped to $\overline{\varphi}^*(\tau) \mapsto \varphi^*(\tau \circ \overline{\varphi}^*) = (\tau \circ \overline{\varphi}) \circ \varphi = \tau \circ (\overline{\varphi} \circ \varphi) = \tau \circ \mathbb{1}_X = \tau$. That is $\varphi^*\overline{\varphi}^*$ is the identity map on $\mathcal{C}(X,T)$ and thereby we see that φ^* is surjective (and $\overline{\varphi}^*$ is injective).

(iv) We start with (b) $\Longrightarrow$ (a) again: Choose $T := Y$, then $\varphi_* : \mathcal{C}(Y,X) \twoheadrightarrow \mathcal{C}(Y,Y)$ is surjective, by assumption. As $\mathbb{1}_Y \in \mathcal{C}(Y,Y)$ there is some $\overline{\varphi} \in \mathcal{C}(Y,X)$ such that $\varphi \circ \overline{\varphi} = \varphi_*(\overline{\varphi}) = \mathbb{1}_Y$ and this is (a). Conversely suppose (a), that is $\varphi \circ \overline{\varphi} = \mathbb{1}_Y$. Then we regard the chain

$$\mathcal{C}(T,Y) \xrightarrow{\overline{\varphi}_*} \mathcal{C}(T,X) \xrightarrow{\varphi_*} \mathcal{C}(T,Y)$$

Starting with any $\tau \in \mathcal{C}(T,Y)$, this is mapped to $\tau \mapsto \overline{\varphi}_*(\tau) = \overline{\varphi} \circ \tau$ which in turn is mapped to $\overline{\varphi}_*(\tau) \mapsto \varphi_*(\overline{\varphi}^* \circ \tau) = \varphi \circ (\overline{\varphi} \circ \tau) = (\varphi \circ \overline{\varphi}) \circ \tau = \mathbb{1}_Y \circ \tau = \tau$. That is $\varphi_*\overline{\varphi}_*$ is the identity map on $\mathcal{C}(T,Y)$ and thereby we see that φ_* is surjective (and $\overline{\varphi}_*$ is injective).

(v) We begin with the equivalence of (c) and (d): The implication (d) $\Longrightarrow$ (c) is trivial, by taking $\psi_X := \psi$ and $\psi_Y := \psi$. Conversely let us prove that $\psi_X = \psi_Y$ in (c): To do this compute:

$$\psi_X \;=\; \psi_X \circ \mathbb{1}_Y \;=\; \psi_X \circ \big(\varphi \circ \psi_Y\big) \;=\; \big(\psi_X \circ \varphi\big) \circ \psi_Y \;=\; \mathbb{1}_X \circ \psi_Y \;=\; \psi_Y$$

Thereby we see that $\psi := \varphi_X = \psi_Y$ is the inverse of φ. We need to prove that this ψ is uniquely determined. So let us suppose we have ψ_1 and ψ_2 that both are inverses of φ. Then we need to show $\psi_1 = \psi_2$. But this can be done in the same manner as before:

$$\psi_1 \;=\; \psi_1 \circ \mathbb{1}_Y \;=\; \psi_1 \circ \big(\varphi \circ \psi_2\big) \;=\; \big(\psi_1 \circ \varphi\big) \circ \psi_2 \;=\; \mathbb{1}_X \circ \psi_2 \;=\; \psi_2$$

Also (a) is equivalent to (e): By (iv) φ is an split-epimorphsim, if and only if φ_* is surjective, for any object T. And φ is a monomorphism, if and only if φ_* is injective, for any object T. Together this is φ_* is bijective, for any object T.

Likewise (b) is equivalent of (f): By (ii) φ is a split-monomorphism, if and only if φ^* is surjective, for any object T. And φ is an epimorphism, if and only if φ^* is injective, for any object T. Together this is φ^* is bijective, for any object T.

Let us now prove the equivalence of (a) and (d): Suppose (a), as φ is a split-monomorphism, there is some $\psi \in \mathcal{C}(Y,X)$, such that $\psi \circ \varphi = \mathbb{1}_X$. Now compute $(\varphi \circ \psi) \circ \varphi = \varphi \circ (\psi \circ \varphi) = \varphi \circ \mathbb{1}_X = \varphi = \mathbb{1}_Y \circ \varphi$. As φ also is an epimorphism, we can conclude $\varphi \circ \psi = \mathbb{1}_Y$ and thereby have (d). And from (d) we immediately get (e): An inverse map of $\varphi^* : \tau \mapsto \tau \circ \varphi$ is obviously given by $(\varphi^{-1})^* : \vartheta \mapsto \vartheta \circ \varphi^{-1}$. But we have seen, that (e) is equivalent to (a) again.

The last equivalence to be proved is that of (b) and (d): Suppose (a), as φ is a split-epimorphism, there is some $\psi \in \mathcal{C}(Y,X)$, such that $\varphi \circ \psi = \mathbb{1}_Y$. Now compute $\varphi \circ (\psi \circ \varphi) = (\varphi \circ \psi) \circ \varphi = \mathbb{1}_Y \circ \varphi = \varphi = \varphi \circ \mathbb{1}_X$. As φ also is a monomorphism, we can conclude $\psi \circ \varphi = \mathbb{1}_X$ and thereby have (d). And from (d) we immediately get (f): An inverse map of $\varphi_* : \tau \mapsto \varphi \circ \tau$ is obviously given by $(\varphi^{-1})_* : \vartheta \mapsto \varphi^{-1} \circ \vartheta$. But we have seen, that (f) is equivalent to (a) again.

□

Proof of (11.11):
We first need to show, that $\Psi \circ \Phi$ is an isomorphism again with inverse $\Phi^{-1} \circ \Psi^{-1}$. Yet this can be done by a straightforward computation

$$\begin{aligned}
\big(\Psi \circ \Phi\big) \circ \big(\Phi^{-1} \circ \Psi^{-1}\big) &= \Psi \circ \big(\Phi \circ \Big(\Phi^{-1} \circ \Psi^{-1}\Big)\big) \\
&= \Psi \circ \big(\Big(\Phi \circ \Phi^{-1}\Big) \circ \Psi^{-1}\big) \\
&= \Psi \circ \big(\mathbb{1}_Y \circ \Psi^{-1}\big) \\
&= \Psi \circ \Psi^{-1} \;=\; \mathbb{1}_Z \\
\big(\Phi^{-1} \circ \Psi^{-1}\big) \circ \big(\Psi \circ \Phi\big) &= \big(\Big(\Phi^{-1} \circ \Psi^{-1}\Big) \circ \Psi\big) \circ \Phi \\
&= \big(\Phi^{-1} \circ \Big(\Psi^{-1} \circ \Psi\Big)\big) \circ \Phi \\
&= \big(\Phi^{-1} \circ \mathbb{1}_Y\big)\Phi \\
&= \Phi^{-1} \circ \Phi \;=\; \mathbb{1}_x
\end{aligned}$$

This second claim are the properties of an equivalence realtion of $\cong$. (1) Is easy, as $\mathbb{1}_X : X \cong X$ clearly is an isomorphism, due to $\mathbb{1}_X \circ \mathbb{1}_X = \mathbb{1}_X$. (2) If $\Phi : X \cong Y$ is an isomorphism, then Φ is the inverse of Φ^{-1}, as well. Hence $\Phi^{-1} : Y \cong X$ is the isomorphy that was claimed to persist. (3) If $\Phi : X \cong Y$ and $\Psi : Y \cong Z$ are isomorphisms, then we have shown above, that $\Psi \circ \Phi : X \cong Z$ is an isomorphy, as well. Hence all three properties are satisfied. □

Proof of (11.13):
As U is universal there is a unique morphism $\Phi : U \to V$, likewise as V is universal there is a unique morphism $\Psi : V \to U$. Hence $\Phi\Psi : U \to U$ is a morphism and as $\mathbb{1}_U : U \to U$ is another morphism the uniquess (U is universal) implies $\Phi\Psi = \mathbb{1}_U$. Likewise we find $\Psi\Phi = \mathbb{1}_V$ and hence $\Phi : U \to V$ is an isomorphism, with inverse morphism $\Psi : V \to U$. For terminal objects we can argue in complete analogy or simply note that terminal objects S and T of $\mathcal{C}$ are universal objects in $\mathcal{C}^{\mathrm{op}}$ such that $S \cong T$ in $\mathcal{C}^{\mathrm{op}}$ and therefore $S \cong T$ in $\mathcal{C}$. □

Proof of (11.14):

(i) Let T be any object of $\mathcal{C}$ and τ and $\tau' \in \mathcal{C}(T,X)$, such that $\varphi \circ \tau = \varphi \circ \tau'$. That is for any $t \in T$ we have $\varphi(\tau(t)) = \varphi(\tau'(t))$. As φ is injective, we get $\tau(t) = \tau'(t)$ from this and as this is true for any $t \in T$ this is $\tau = \tau'$ again. That is an injective morphism is an monomorphism.

Likewise for morphisms τ, $\tau' \in \mathcal{C}(Y,T)$ satisfying $\tau \circ \varphi = \tau' \circ \varphi$ we prove that the surjectivity of φ implies $\tau = \tau'$: Consider any $y \in Y$, as φ is surjective, there is some $x \in X$ such that $\varphi(x) = y$. And from this we get $\tau(y) = \tau \circ \varphi(x) = \tau' \circ \varphi(x) = \tau'(y)$. Again, as this is true for any $y \in Y$, we see $\tau = \tau'$ which is the property of an epimorphism.

(ii) Suppose $\varphi \in \mathcal{C}(X,Y)$ is a split-monomorphism. We have to verify that for any object T and any morphisms τ, $\tau' \in \mathcal{C}(T,X)$ with $\varphi \circ \tau = \varphi \circ \tau'$ we get $\tau = \tau'$. But by assumption there is some $\overline{\varphi} \in \mathcal{C}(Y,X)$ such that $\overline{\varphi} \circ \varphi = \mathbb{1}_X$. It suffices to apply such an $\overline{\varphi}$ to the equation, as this implies

$$\tau \;=\; \mathbb{1}_X \circ \tau \;=\; \big(\overline{\varphi} \circ \varphi\big) \circ \tau \;=\; \overline{\varphi} \circ \big(\varphi \circ \tau\big) \;=\; \overline{\varphi} \circ \big(\varphi \circ \tau'\big) \;=\; \big(\overline{\varphi} \circ \varphi\big) \circ \tau' \;=\; \mathbb{1}_X \circ \tau' \;=\; \tau'$$

Likewise for a split-epimorphism $\varphi \in \mathcal{C}(X,Y)$: We have to verify that for any object Z and any morphisms ζ, $\zeta' \in \mathcal{C}(Y,Z)$ with $\tau \circ \varphi = \zeta' \circ \varphi$ we get $\zeta = \zeta'$. But by assumption there is some $\overline{\varphi} \in \mathcal{C}(Y,X)$ such that $\varphi \circ \overline{\varphi} = \mathbb{1}_Y$. It suffices to apply such an $\overline{\varphi}$ to the equation, as this implies

$$\zeta \;=\; \zeta \circ \mathbb{1}_Y \;=\; \zeta \circ \big(\varphi \circ \overline{\varphi}\big) \;=\; \big(\zeta \circ \varphi\big) \circ \overline{\varphi} \;=\; \big(\zeta' \circ \varphi\big) \circ \overline{\varphi} \;=\; \zeta' \circ \big(\varphi \circ \overline{\varphi}\big) \;=\; \zeta' \circ \mathbb{1}_Y \;=\; \zeta'$$

(iii) If φ is a monomorphism, then for any object $T \in \mathrm{obj}(\mathcal{C})$ the map $\mathcal{C}(T,X) \hookrightarrow \mathcal{C}(T,Y) : \tau \mapsto \varphi \circ \tau$ is injective. And if φ is a monomorphism, as well, then the map $\mathcal{C}(X,Y) \hookrightarrow \mathcal{C}(X,Z) : \xi \mapsto \psi \circ \xi$ is injective, too. Hence the composition of these maps $\mathcal{C}(T,X) \hookrightarrow \mathcal{C}(T,Z) : \tau \mapsto \psi \circ (\varphi \circ \tau)$ is injective again. And as $\psi \circ (\varphi \circ \tau) = (\psi \circ \varphi) \circ \tau$ this injectivity is just what it takes to make $\psi \circ \varphi$ a monomorpism again. Conversely, if $\psi \circ \varphi$ is a monomorphism, let us prove, that φ has to be a monomorphism: That is we consider any τ, $\tau' \in \mathcal{C}(T,X)$ such that $\varphi \circ \tau = \varphi \circ \tau'$ and have to show $\tau = \tau'$. But this is easy: apply ψ from the left. As $\psi \circ \varphi$ is a monomorphism, we get $\tau = \tau'$ from

$$\big(\psi \circ \varphi\big) \circ \tau \;=\; \psi \circ \big(\varphi \circ \tau\big) \;=\; \psi \circ \big(\varphi \circ \tau'\big) \;=\; \big(\psi \circ \varphi\big) \circ \tau'$$

(iv) If ψ is an epimorphism, then for any object $T \in \mathrm{obj}(\mathcal{C})$ the map $\mathcal{C}(Z,T) \hookrightarrow \mathcal{C}(Y,T) : \tau \mapsto \tau \circ \psi$ is injective. And if φ is an epimorphism, as well, then the map $\mathcal{C}(Y,T) \hookrightarrow \mathcal{C}(X,Z) : \zeta \mapsto \zeta \circ \varphi$ is injective, too. Hence the composition of these maps $\mathcal{C}(Z,T) \hookrightarrow \mathcal{C}(X,T) : \tau \mapsto (\tau \circ \psi) \circ \varphi$ is injective again. And as $(\tau \circ \psi) \circ \varphi = \tau \circ (\psi \circ \varphi)$ this injectivity is just what it takes to make $\psi \circ \varphi$ an epimorpism again. Conversely, if $\psi \circ \varphi$ is an epimorphism, let us prove, that ψ has to be an epimorphism: That is we consider any τ, $\tau' \in \mathcal{C}(Z,T)$ such that $\tau \circ \psi = \tau' \circ \psi$ and have to show $\tau = \tau'$. But this is easy: apply φ from the right. As $\psi \circ \varphi$ is an epimorphism, we get $\tau = \tau'$ from

$$\tau \circ \big(\psi \circ \varphi\big) \;=\; \big(\tau \circ \psi\big) \circ \varphi \;=\; \big(\tau' \circ \psi\big) \circ \varphi \;=\; \tau' \circ \big(\psi \circ \varphi\big)$$

(v) As Y is an initial object, there is a uniquely defined morphism $\iota \in \mathcal{C}(Y,X)$. Thus $\mathbb{1}_Y$ and $\varphi \circ \iota$ both are morphisms in $\mathcal{C}(Y,Y)$. But as Y is an initial object, there is only one such morphism, such that $\varphi \circ \iota = \mathbb{1}_Y$. But from this we also get $\varphi \circ (\iota \circ \varphi) = (\varphi \circ \iota) \circ \varphi = \mathbb{1}_Y \circ \varphi = \varphi \circ \mathbb{1}_X$. And as φ is a monomorphism, this implies $\iota \circ \varphi = \mathbb{1}_X$. Together ι is the inverse morphism of φ.

(vi) As Y is a terminal object, there is a uniquely defined morphism $\pi \in \mathcal{C}(Z,Y)$. Thus $\mathbb{1}_Y$ and $\pi \circ \psi$ both are morphisms in $\mathcal{C}(Y,Y)$. But as Y is a terminal object, there is only one such morphism, such that $\pi \circ \psi = \mathbb{1}_Y$. But from this we also get $\mathbb{1}_Z \circ \psi = \psi \circ \mathbb{1}_Y = \psi \circ (\pi \circ \psi) = (\psi \circ \pi) \circ \psi$. And as ψ is an epimorphism, this implies $\mathbb{1}_Z = \psi \circ \pi$. Together π is the inverse morphism of ψ.

□

Proof of (11.15):

(i) If f is injective, then f has a left-inverse, by (0.10.(a)) and this already is the property of a split-monomorphism. A split-monomorphism already is a monomorphism, by (11.14.(ii)). So it remains to prove that a monomorphism f in **Set** is injective: Consider any two x, $x' \in X$, where $f : X \to Y$ and suppose $f(x) = f(x')$. Let T be a one-point set, e.g. $T = \{0\}$ and define $\tau : T \to X$ by $\tau(0) := x$ and $\tau' : T \to X$ by $\tau'(0) := x'$. Then we have $f\tau(0) = f(x) = f(x') = f\tau(0)$ such that $f\tau = f\tau'$. As f is assumed to be a monomorphism, we get $\tau = \tau'$, which is $x = \tau(0) = \tau'(0) = x'$. And this is the injectivity of f again.

- If f is surjective, then f has a right-inverse, by (0.10.(a)) and this already is the property of a split-epimorphism. A split-epimorphism already is an epimorphism, by (11.14.(ii)). So it remains to prove that an epimorphism f in **Set** is surjective: Suppose there was some $z \in Y$ with $z \in Y \setminus f(X)$, where $f : X \to Y$. Let $T := Y \sqcup \{t, t'\}$ where t and t' are any two distinct elements not contained in Y before, e.g. $t = (Y, 1)$ and $t' = (Y, 2)$. Now define $\tau : Y \to T$ by $\tau(y) := y$ for $y \neq z$ and $\tau(z) := t$ Likewise we let $\tau'(y) := y$ for $y \neq z$ and $\tau'(z) := t'$. As $z \in Y \setminus f(X)$, for any $x \in X$ we get $\tau f(x) = f(x) = \tau' f(x)$ such that $\tau f = \tau' f$. As f is assumed to be an epimorphism, we get $\tau = \tau'$, such that $t = \tau(z) = \tau'(z) = t'$. But this contradicts the construction of t and t', such that there cannot be any $z \in Y \setminus f(X)$. But this means $f(X) = Y$, which is the surjectivity of f.

(ii) If $\varphi : M \to N$ is injective, then φ already is a monomorphism, according to (11.14.(i)). Conversely, consider a monomorphism φ and any two x, $x' \in M$ such that $\varphi(x) = \varphi(x')$. We pick up $T := R$ as an R-module and define the homomorphisms $\tau : R \to M$ by $\tau(a) := ax$ and $\tau' : R \to M$ by $\tau'(a) := ax'$. As φ is R-linear, we get $\varphi\tau(a) = \varphi(ax) = a\varphi(x) = a\varphi(x') = \varphi(ax') = \varphi\tau'(a)$. That is $\varphi\tau = \varphi\tau'$ and hence $\tau = \tau'$, as φ was assumed to be a monomorphism. In particular $x = \tau(1) = \tau'(1) = x'$, which is the injectivity of φ.

- If $\varphi : M \to N$ is surjective, then φ already is an epimorphism, according to (11.14.(i)). Conversely, consider an epimorphism φ and define the R-module $T := N/\mathrm{im}(\varphi)$. Now regard the homomorphisms $\tau : N \to T : y \mapsto 0$ and $\tau' : N \to T : y \mapsto y + \mathrm{im}(\varphi)$. For any $x \in M$ we get $\tau\varphi(x) = 0 = 0 + \mathrm{im}(\varphi) = \varphi(x) + \mathrm{im}(\varphi) = \tau'\varphi(x)$, such that $\tau\varphi = \tau'\varphi$. As φ is an epimorphism, this implies $\tau = \tau'$ and this is $0 = \tau(y) = \tau'(y) = y + \mathrm{im}(\varphi)$ for any $y \in N$. In other words $y \in \mathrm{im}(\varphi)$ and thereby φ is surjective, as $y \in N$ is arbitrary.

- If $\varphi : M \to N$ is a bijective homomorphism, then φ is an isomorphism with inverse $\varphi^{-1} : N \to M$, according to (3.77.(b)). Conversely, if φ is an isomorphism, then there is a inverse morphism $\psi : N \to M$ of φ. In particular Ψ is the inverse map of φ and thereby φ is bijective.

(iii) If $\varphi : R \to S$ is injective, then φ already is a monomorphism, according to (11.14.(i)). Conversely, consider a monomorphism $\varphi : R \to S$, we have to verify, that φ is injective: Hence we consider any two elements a, $a' \in R$ such that $\varphi(a) = \varphi(a')$. Take the polynomial ring $T := \mathbb{Z}[t]$ and define the homomorphisms $\tau : T \to R : f \mapsto f(a)$ and likewise $\tau' : T \to R : f \mapsto f(a')$. As φ is a homomorphism of rings we get $\varphi\tau(f) = \varphi(f(a)) = f(\varphi(a)) = f(\varphi(a')) = \varphi(f(a')) = \varphi\tau'(f)$ for any $f \in T$, such that $\varphi\tau = \varphi\tau'$. As φ is a monomorphism we conclude $\tau = \tau'$ and thereby $a = \tau(t) = \tau'(t) = a'$, which is the injectivity of φ.

- If $\varphi : R \to S$ is a bijective homomorphism, then φ is an isomorphism with inverse $\varphi^{-1} : S \to R$, according to (1.80.(ii).(b)). Conversely, if φ is an isomorphism, then there is an inverse morphism

$\psi : S \to R$ of φ. In particular ψ is the inverse map of φ and thereby φ is bijective.

- Let us verify, that $\zeta(k) := k/1$ is an epimorphism $\mathbb{Z} \to \mathbb{Q}$. Consider any ring T and τ, $\tau' : \mathbb{Q} \to T$ such that $\tau\zeta = \tau'\zeta$. First of all, note that $1_T = \tau(1/1) = \tau(b/b) = \tau(b/1)\tau(1/b)$. That is for any $b \neq 0$ we have $\tau\zeta(b) = \tau(b/1) \in T^*$. Also note that for any $a \in \mathbb{Z}$ we have $\tau(a/1) = \tau\zeta(a) = \tau'\zeta(a) = \tau'(a/1)$. But for any $b \neq 0$ we thereby also get

$$\tau\left(\frac{b}{1}\right)\tau\left(\frac{a}{b}\right) \;=\; \tau\left(\frac{b}{1}\frac{a}{b}\right) \;=\; \tau\left(\frac{a}{1}\right) \;=\; \tau'\left(\frac{a}{1}\right) \;=\; \tau'\left(\frac{b}{1}\frac{a}{b}\right) \;=\; \tau'\left(\frac{b}{1}\right)\tau'\left(\frac{a}{b}\right)$$

 As $\tau(b/1) = \tau'(b/1)$ is a unit in T we conclude $\tau(a/b) = \tau'(a/b)$ for any $a \in \mathbb{Z}$ and $b \neq 0$. That is for any $a/b \in \mathbb{Q}$ and hence $\tau = \tau'$. In particular ζ is an epimorphism in **Ring**.

(iv) As all these categories are concrete, injective morphisms are monomorphisms and surjective morphisms are epimorphisms, according to (11.14.(i)). And isomorphisms trivially are bijective morphisms, as the inverse morphism also is an inverse map. Thus for all these categories, in any equivalence we only have to check one direction.

 For **Set** we have already seen in (i), that any monomorphism is injective and any epimorphism is surjective. And for a bijective morphism the inverse map also is an inverse morphism, as any map is a morphism in this category.

- Let us regard **Group** next and start with a monomorphism $\varphi : G \to H$. We have to verify, that φ is injective: Hence we consider any two elements x, $x' \in G$ such that $\varphi(x) = \varphi(x')$. Take $T := \mathbb{Z}$ and define the homomorphisms $\tau : \mathbb{Z} \to G : k \mapsto x^k$ and likewise $\tau' : \mathbb{Z} \to G : k \mapsto x'^k$. Then it is clear, that for any $k \in \mathbb{Z}$ we get $\varphi\tau(k) = \varphi(x^k) = \varphi(x)^k = \varphi(x')^k = \varphi(x'^k) = \varphi\tau'(k)$ such that $\varphi\tau = \varphi\tau'$. As φ is a monomorphism we conclude $\tau = \tau'$ and thereby $x = \tau(1) = \tau'(1) = x'$, which is the injectivity of φ.

 Now for an epimorphism $\varphi : G \to H$: Let us abbreviate $P := \mathrm{im}(\varphi)$ which is a subgroup of H. Then we can regard $X := H/P$ as a set. Pick up another element ∞ not in X before, e.g. $\infty := X$, and let $Y := X \cup \{\infty\}$. Then we consider the permutation group

$$T \;:=\; S_Y$$

 Let $\sigma \in T$ be the transposition $\sigma := (eP\ \infty)$. We can turn any element $h \in H$ into a permutation on X by multiplication from the left. Clearly this is an (even injective) homomorphism of groups. And thereby we find a homomorphism of groups of the form

$$\tau \;:\; H \to T \;:\; k \mapsto \begin{cases} y \mapsto khP \text{ if } y = hP \in X \\ \qquad\quad \infty \text{ if } y = \infty \notin X \end{cases}$$

 We define another homomorphism of groups τ' by conjugating τ with the transposition $\sigma \in T$, i.e.

$$\tau \;:\; H \to T \;:\; k \mapsto \sigma\tau(k)\sigma^{-1}$$

 Consider any $g \in G$ and compute $\tau(\varphi(g))(eP)$. By construction this is $\varphi(g)eP = \varphi(g)P = eP$, as $\varphi(g) \in P$. That is eP is fixed under $\tau(\varphi(g))$. But so is ∞ and hence $\tau(\varphi(g))$ and σ have disjoint

domains. Therefore they commute, according to (1.14.(iii)). That is we have $\sigma\tau(\varphi(g)) = \tau(\varphi(g))\sigma$ and thereby $\tau'(\varphi(g)) = \sigma\tau(\varphi(g))\sigma^{-1} = \tau(\varphi(g))$ for any $g \in G$. In other words that is $\tau'\varphi = \tau\varphi$ and as φ was assumed to be an epimorphism, this implies $\tau' = \tau$. That is for any $k \in H$ we have

$$\sigma\tau(k)\sigma^{-1} \;=\; \tau'(k) \;=\; \tau(k)$$

and thereby $\sigma\tau(k) = \tau(k)\sigma$ commute. Suppose there was some $k \in H$ with $tP := \tau(k)(eP) \neq eP$. As σ only acts on eP and ∞ but tP is neither, we then had $\sigma\tau(k)(eP) = \sigma(tP) = tP$. But on the other hand we then also had $\tau(k)\sigma(eP) = \tau(k)(\infty) = \infty$. But now $tP \neq \infty$ contradicts $\sigma\tau(k)(eP) = \tau(k)\sigma(eP)$ and hence this cannot be. We conclude that is eP has to be fixed under any $\tau(k)$, for any $k \in H$. In other words $eP = \tau(k)(eP) = keP = kP$, which is $k \in P = \mathrm{im}(\varphi)$. As this is true for any $k \in H$, we find that φ truly has to be surjective.

If $\varphi : G \to H$ is a bijective homomorphism of groups, then its inverse is a homomorphism of groups again. This can be done in the standard way: Consider any $x, y \in H$, as φ is surjective, there are $u, v \in G$ such that $x = \varphi(u)$ and $y = \varphi(v)$. Using these we are able to compute

$$\varphi^{-1}(xy) \;=\; \varphi^{-1}\big(\varphi(u)\varphi(v)\big) \;=\; \varphi^{-1}\big(\varphi(uv)\big) \;=\; uv \;=\; \varphi^{-1}(x)\varphi^{-1}(y)$$

As $\varphi\varphi^{-1} = \mathbb{1}_H$ and $\varphi^{-1}\varphi = \mathbb{1}_G$ is clear for the inverse function and φ^{-1} inherits the properties of a homomorphism of groups from φ we see, that φ^{-1} is the inverse morphism of φ.

- The case $\mathbf{Alg}_R$ is much the same, as for **Ring**: If A and B are R-algebras and $\varphi : A \to B$ is a momonorphism, then take to the polynomial ring $T := R[t]$, which is an R-algebra again, as R is commutative. We have to verify, that φ is injective: Hence we consider any two elements $u, u' \in A$ such that $\varphi(u) = \varphi(u')$ and define the homomorphisms $\tau : T \to A : f \mapsto f(u)$ and likewise $\tau' : T \to A : f \mapsto f(u')$. As φ is a homomorphism of R-algebras can compute again: $\varphi\tau(f) = \varphi(f(u)) = f(\varphi(u)) = f(\varphi(u')) = \varphi(f(u')) = \varphi\tau'(f)$ for any $f \in T$, such that $\varphi\tau = \varphi\tau'$. As φ is a monomorphism we conclude $\tau = \tau'$ and thereby $u = \tau(t) = \tau'(t) = u'$, which is the injectivity of φ.

 If $\varphi : A \to B$ is a bijective homomorphism, then the inverse map φ^{-1} is both, a homomorphism of rings and of R-modules, according to (1.80.(ii).(b)) and (3.77.(b)) respectively. Together φ^{-1} is a homomorphism of R-algebras and thereby φ is an isomorphism. Conversely, if φ is an isomorphism, then there is an inverse morphism $\psi : B \to A$ of φ. In particular ψ is the inverse map of φ and thereby φ is bijective.

□

Proof of (11.17):

- Let us first prove that $\varphi \mid \psi$ is reflexive and transitive: For any $\psi \in \mathcal{C}(X, Z)$ we clearly have $\psi = \psi \circ \mathbb{1}_X$ and thereby $\psi \mid \psi$. And if $\psi_1 \mid \psi_2$ and $\psi_2 \mid \psi_3$ then by definition there are $\psi_1' \in \mathcal{C}(X_1, X_2)$ and $\psi_2' \in \mathcal{C}(X_2, X_3)$ such that $\psi_3 = \psi_2 \circ \psi_2'$ and $\psi_2 = \psi_1 \circ \psi_1'$. Combining these we find $\psi_3 = (\psi_1 \circ \psi_1') \circ \psi_2' = \psi_1 \circ (\psi_1' \circ \psi_2')$ and thereby $\psi_1 \mid \psi_3$.

 The properties of an equivalence relation are straightforward: We get (1) from the reflexivity of the factors relation. Property (2) is trivial, as the relation $\sim$ has been defined by a symmetric condition. And (3) is clear by the transitivity of the factors relation - just pair the factors relations.

- *Uniquely determined*: Now suppose $\psi_2 = \psi_1 \circ \psi_1'$ where ψ_1 and ψ_2 are monomorphisms. Also suppose there was another $\psi_1'' \in \mathcal{C}(X_2, X_1)$ such that $\psi_2 = \psi_1 \circ \psi_1''$. Then we had $\psi_1 \circ \psi_1' = \psi_1 \circ \psi_1''$ and as ψ_1 is a monomorphism, we conclude $\psi_1' = \psi_1''$. That is ψ_1' is uniquely determined and in complete analogy we see, that ψ_2' is uniquely determined, as ψ_2 is a monomorphism, too.

- *Mutually inverse*: By assumption we have $\psi_2 = \psi_1 \circ \psi_1'$ and $\psi_1 = \psi_2 \circ \psi_2'$. Plugging the first equation into the second, we see $\psi_1 \circ \mathbb{1}_{X_1} = \psi_1 = (\psi_1 \circ \psi_1') \circ \psi_2' = \psi_1 \circ (\psi_1' \circ \psi_2')$. As ψ_1 is a monomorphism, this yields $\mathbb{1}_{X_1} = \psi_1' \circ \psi_2'$ and the other way around we also find $\mathbb{1}_{X_2} = \psi_2' \circ \psi_1'$. That is the morphisms ψ_1' and ψ_2' are the inverse morphism of one and another.

□

Proof of (11.20):
The first equality is easy: $\psi \circ 0 = \psi \circ (0+0) = \psi \circ 0 + \psi \circ 0$. Subtracting one $\psi \circ 0$ from this equation we end up at $0 = \psi \circ 0$. In complete analogy we can prove $0 = 0 \circ \varphi$.
Using the first two equations we can also prove the second two equations: $0 = \psi \circ 0 = \psi \circ (\varphi + (-\varphi)) = \psi \circ \varphi + \psi \circ (-\varphi)$. Subtracting $\psi \circ \varphi$ from this equation we end up with $-(\psi \circ \varphi) = \psi \circ (-\varphi)$ and in complete analogy we can prove $-(\psi \circ \varphi) = (-\psi) \circ \varphi$. □

Proof of (11.26):

(i) Let $\Phi^{-1} \in \mathcal{C}(Y, X)$ be the inverse morphism of Φ, then we have $\Phi^{-1} \circ \Phi = \mathbb{1}_X$ and $\Phi \circ \Phi^{-1} = \mathbb{1}_Y$. In particular $\mathbb{1}_{F(X)} = F(\mathbb{1}_X) = F(\Phi^{-1} \circ \Phi) = F(\Phi^{-1}) \circ F(\Phi)$. In complete analogy we find that $\mathbb{1}_{F(Y)} = F(\Phi) \circ F(\Phi^{-1})$. Thus we see that $F(\Phi^{-1})$ is the inverse morphism of $F(\Phi)$ and in particular $F(\Phi)$ is invertible.

(ii) As F is full, there are some morphisms Φ and Ψ of $\mathcal{C}$ such that $F(\Phi) = \Theta$ and $F(\Psi) = \Theta^{-1}$. For these morphisms we find $F(\Phi \circ \Psi) = F(\Phi) \circ F(\Psi) = \Theta \circ \Theta^{-1} = \mathbb{1}_{F(Y)} = F(\mathbb{1}_Y)$. As F also is faithful, we get $\Phi \circ \Psi = \mathbb{1}_Y$ from this. In complete analogy we find $\Psi \circ \Phi = \mathbb{1}_X$ and thereby Φ is an isomorphism of $\mathcal{C}$ with inverse morphism Φ. This isomorphism is uniquely determined by $F(\Phi) = \Theta$, as F is faithful.

(iii) Let us abbreviate $D := F(X) = F(Y)$. Clearly $\mathbb{1}_D$ is an isomorphism $\mathbb{1}_D : D \xrightarrow{\sim} D$. Now by (ii) there is an isomorphism $\Phi : X \xrightarrow{\sim} Y$ such that $F(\Phi) = \mathbb{1}_D$. In particular $X \cong Y$ are isomorphic.

□

Proof of (11.31):

(i) Property (1) is obvious: If $E = \mathbb{1}$ and $\overline{E} = \mathbb{1}$ is the identity functor on $\mathcal{C}$, then the isomorphisms $\Phi_X : X \xrightarrow{\sim} \overline{E}E(X) = X$ are just the identities $\Phi_X = \mathbb{1}_X$ and likewise for Θ_X. Property (2) is trivial, as the properties (1), (2) and (3), (4) of an equivalence of categories are symmetric under interchanging E and $\overline{E}$. The only property that requires a little effort is the transitivity (3): Consider any two objects U, $U' \in \mathrm{obj}(\mathcal{B})$ and a morphism $\varphi \in \mathcal{B}(U, U')$. By assumption $(D, \overline{D}) : \mathcal{B} \sim \mathcal{C}$ there are isomorphisms $\Gamma_U : U \xrightarrow{\sim} \overline{D}D(U)$ such that the following diagram commutes

$$\begin{array}{ccc} U & \xrightarrow{\Gamma_U} & \overline{D}(D(U)) \\ \downarrow & & \downarrow \\ U' & \xrightarrow{\Gamma_{U'}} & \overline{D}(D(U')) \end{array}$$

Let $X := D(U)$, $X' := D(U')$ and $\psi := D(\varphi) \in \mathcal{C}(X, X')$. Then by assumption $(E, \overline{E}) : \mathcal{C} \sim \mathcal{D}$ there are isomorphisms $\Phi_X : X \xrightarrow{\sim} \overline{E}E(X)$ such that the following diagram commutes, as well

$$\begin{array}{ccc} X & \xrightarrow{\Phi_X} & \overline{E}(E(X)) = \overline{E}ED(U) \\ \downarrow & & \downarrow \\ X' & \xrightarrow{\Phi_{X'}} & \overline{E}(E(X')) = \overline{E}ED(U') \end{array}$$

Apply the functor $\overline{D}$ to this diagram, by (11.26) the isomorphisms Φ_X (from left to right) remain isomorphisms and the commutativity is preserved by functors, as well. Then we may compose these diagrams to find

$$\begin{array}{ccccc} U & \xrightarrow{\Gamma_U} & \overline{D}(D(U)) = \overline{D}(X) & \xrightarrow{\overline{D}(\Phi_X)} & \overline{D}\overline{E}ED(U) \\ \downarrow & & \downarrow & & \downarrow \\ U' & \xrightarrow{\Gamma_{U'}} & \overline{D}(D(U')) = \overline{D}(X') & \xrightarrow{\overline{D}(\Phi_{X'})} & \overline{D}\overline{E}ED(U') \end{array}$$

Hereby the morphisms pointing top-down are φ, $\overline{D}(\psi) = D(\varphi)$ and $\overline{D}\overline{E}ED(\varphi)$. Hence we find a family of isomorphisms $\overline{D}(\Phi_{D(U)})\Gamma_U : U \xrightarrow{\sim} \overline{D}\overline{E}ED(U)$ that yield commutative diagrams with morphimsm $\varphi : U \to U'$. That is ED satisfies property (3) of an equivalence of categories. By the symmetry of property (4), it is clear that we also find compatible isomorphisms $Y \xrightarrow{\sim} ED\overline{D}\overline{E}$ such that property (4) is satisfied, as well. Altogether $(ED, \overline{D}\overline{E}) : \mathcal{B} \sim \mathcal{D}$ is an equivalence of categories.

(ii) We start by proving that E is faithful, that is we regard any two objects X, $X' \in \mathrm{obj}(\mathcal{C})$ and let $Y := E(X)$ and $Y' := E(X')$. Then we have to prove, that the following map is injective

$$\mathcal{C}(X, X') \to \mathcal{D}(Y, Y') \; : \; \varphi \mapsto E(\varphi)$$

But by assumption we have another functor $\overline{E} : \mathcal{D}(Y, Y') \to \mathcal{C}(Z, Z')$ where we let $Z := \overline{E}(Y)$ and $Z' := \overline{E}(Y')$ satisfying $\overline{E}E(\varphi) = \Phi_{X'}\,\varphi\,\Phi_X^{-1}$ for some isomorphisms $\Phi_{X'}$ and Φ_X. So supposed we had some morphisms φ_1, $\varphi_2 \in \mathcal{C}(X, X')$ such that $E(\varphi_1) = E(\varphi_2)$, then we could apply $\overline{E}$ to find

$$\Phi_{X'}\,\varphi_1\,\Phi_X^{-1} \; = \; \overline{E}E(\varphi_1) \; = \; \overline{E}E(\varphi_2) \; = \; \Phi_{X'}\,\varphi_2\,\Phi_X^{-1}$$

But as $\Phi_{X'}$ and Φ_X are isomorphisms we hence get $\varphi_1 = \varphi_2$ which is the injectivity of E on the morphisms. That is E is faithful. In complete analogy we find, that $\overline{E}$ is faithful, too. To prove that E also is full we regard any morphism $\psi \in \mathcal{D}(Y, Y')$ where $Y := E(X)$ and $Y' := E(X')$ and X, $X' \in \mathrm{obj}(\mathcal{C})$ are arbitrary. Then we have to find some morphism $\varphi \in \mathcal{C}(X, X')$, such that $E(\varphi) = \psi$. But if we define

$$\varphi \; := \; \Phi_{X'}^{-1}\,\overline{E}(\psi)\,\Phi_X$$

then we have $\overline{E}E(\varphi) = \Phi_{X'}\,\varphi\,\Phi_X^{-1} = \overline{E}(\psi)$. But as $\overline{E}$ is faithful, we conclude, that $E(\varphi) = \psi$. And this is just what we needed for E being full. In complete analogy, we see, that $\overline{E}$ is full, as well. It remains to prove that E (and likewise $\overline{E}$) are essentially surjective: That is we are given any object $Y \in \mathrm{obj}(\mathcal{D})$ and need to find an object $X \in \mathrm{obj}(\mathcal{C})$, such that $E(X) \cong Y$. It stands to reason to take $X := \overline{E}(Y)$, then by property (4) of an equivalence of categories there is an isomorphism $\Theta_Y : Y \xrightarrow{\sim} E\overline{E}(Y) = E(X)$, which is just what we needed. Clearly the essential surjectivity of $\overline{E}$

follows from the analogous argument and property (3).

(iii) Let us first construct $\overline{E}$: Given any object $Y \in \mathrm{obj}(\mathcal{D})$ we can choose an object $X_Y \in \mathrm{obj}(\mathcal{C})$ and a morphism Θ_Y, such that $\Theta_Y : Y \xrightarrow{\sim} E(X_Y)$ is an isomorphism. This is due to the essential surjectivity of E. Thus we let $\overline{E}(Y) := X_Y$ and thereby get

$$\Theta_Y \ : \ Y \ \xrightarrow{\sim} \ E\overline{E}(Y)$$

Now consider a morphism $\psi \in \mathcal{D}(Y, Y')$ and abbreviate $X := \overline{E}(Y)$ and $X' := \overline{E}(Y')$. The following diagram commutes if the top-down maps are taken to be ψ and $\Theta_{Y'} \circ \psi \circ \Theta_Y^{-1}$ respectively:

$$\begin{array}{ccc} Y & \xrightarrow{\Theta_Y} & E(X) \\ \downarrow & & \downarrow \\ Y' & \xrightarrow{\Theta_{Y'}} & E(X') \end{array}$$

That is $\Theta_{Y'} \circ \psi \circ \Theta_Y^{-1} \in \mathcal{D}(E(X), E(X'))$. As E is full and faithful, there is a uniquely determined morphism $\varphi \in \mathcal{C}(X, X')$ such that $E(\varphi) = \Theta_{Y'} \circ \psi \circ \Theta_Y^{-1}$. We then define $\overline{E}(\psi) := \varphi$, that is $\overline{E}(\psi)$ is uniquely defined by the property

$$E\big(\overline{E}(\psi)\big) \ = \ \Theta_{Y'} \circ \psi \circ \Theta_Y^{-1}$$

We first have to check, that this definition of $\overline{E}$ truly yields a functor. That is we have to verify, that for any two morphisms $\psi_1 \in \mathcal{D}(Y_1, Y_2)$ and $\psi_2 \in \mathcal{D}(Y_2, Y_3)$ we get $\overline{E}(\psi_2 \circ \psi_1) = \overline{E}(\psi_2) \circ \overline{E}(\psi_1)$. However it is clear, that

$$\Theta_{Y_3} \circ \big(\psi_2 \circ \psi_1\big) \circ \Theta_{Y_1}^{-1} \ = \ \big(\Theta_{Y_3} \circ \psi_2 \circ \Theta_{Y_2}^{-1}\big) \circ \big(\Theta_{Y_2} \circ \psi_1 \circ \Theta_{Y_1}^{-1}\big)$$

That is $E\overline{E}(\psi_2 \circ \psi_1) = E\overline{E}(\psi_2) \circ E\overline{E}(\psi_1) = E(\overline{E}(\psi_2) \circ \overline{E}(\psi_1))$. And as E is faithful, we can strip E and find the functorial property $\overline{E}(\psi_2 \circ \psi_1) = \overline{E}(\psi_2) \circ \overline{E}(\psi_1)$. Property (4) of equivalences of categories is already satisfied by the definition of $\overline{E}(\psi)$. It only remains to verify property (3), that is we have to construct the isomorphisms $\Phi_X : X \xrightarrow{\sim} \overline{E}E(X)$: Given any object $X \in \mathrm{obj}(\mathcal{C})$ let $X' := X_{E(X)} = \overline{E}E(X)$. Then

$$\Theta_{E(X)} \ : \ E(X) \ \xrightarrow{\sim} \ E\overline{E}\big(E(X)\big) = E(X')$$

is an isomorphism. As E is full and faithful this implies, that there is a uniquely determined isomorphism $\Phi_X : X \xrightarrow{\sim} X' = \overline{E}E(X)$ satisfying $E(\Phi_X) = \Theta_{E(X)}$, according to (11.26.(ii)). Now consider any morphism $\varphi \in \mathcal{C}(X, X')$, we have to verify the commutativity of the diagram in property (3). Just apply the functor E and abbreviate $\psi := E(\varphi)$, then we will verify the commutativity of the following diagram

$$\begin{array}{ccc} E(X) & \xrightarrow{\psi} & E(X') \\ \downarrow & & \downarrow \\ E\overline{E}E(X) & \xrightarrow{E\overline{E}(\psi)} & E\overline{E}E(X') \end{array}$$

The top-down maps have been Φ_X and $\Phi_{X'}$ respectively. Under E they turned into $\Theta_{E(X)}$ and

$\Theta_{E(X')}$. And by construction $E\overline{E}(\psi)$ is $\Theta_{E(X')} \circ \psi \circ \Theta^{-1}_{E(X)}$. That is the above diagram *is* commutative. But as E is faithful we can strip E again and this means the diagram in property (3) is commutative. Altogether we have proved, that $(E, \overline{E})$ satisfies the properties of an equivalence of categories.

(iv) This statement is purely definitional: In (a) $\Longrightarrow$ (b) property (3) of the equivalence of categories yields a collection $\Phi = (\Phi_X)$ of morphisms, which is a natural transformation $\Phi : \mathbb{1}_{\mathcal{C}} \rightrightarrows \overline{E}E$. And as all the $\Phi_X : X \xrightarrow{\sim} \overline{E}E(X)$ are assumed to be isomorphisms, this Φ is a natural isomorphism. Likewise property (4) of the equivalence of categories makes $\Theta = (\Theta_Y)$ a natural isomorphism of the form $\Theta : \mathbb{1}_{\mathcal{D}} \rightrightarrows E\overline{E}$. Conversely, for (b) $\Longrightarrow$ (a), to say that $\Phi : \mathbb{1}_{\mathcal{C}} \rightrightarrows \overline{E}E$ is a natural transformation, is the commutativity in property (3) again. And as Φ is a natural isomorphism, any Φ_X is an isomorphism. And the same is true for the natural isomorphism $\Theta : \mathbb{1}_{\mathcal{D}} \rightrightarrows E\overline{E}$, of course.

□

Proof of (11.33):

(i) Clearly $\varphi = \mathbb{1}_P$ is a morphism $\mathbb{1}_P : P \to P$ satisfying $\pi_i = \pi_i \circ \varphi$. And as (P, π_i) is a product of the X_i this has to the *only* morphism $\varphi \in \mathcal{C}(P, P)$ that makes all these diagrams commute. Now apply (3) to (P', π'_i), then we find a morphism $\pi' : P' \to P$ such that $\pi'_i = \pi_i \circ \pi'$.

Likewise (P', π'_i) is a product of the X_i so by the same reasoning, as above, we see that $\varphi' = \mathbb{1}_{P'} \in \mathcal{C}(P', P')$ is the one and only morphism making all the diagrams $\pi'_i = \pi'_i \circ \varphi'$ commute. And applying (3) to (P, π_i) we also find a morphism $\pi : P \to P'$ such that $\pi_i = \pi'_i \circ \pi$.

Let us now compose these morphisms π' and π: We find $\pi_i \circ (\pi' \circ \pi) = (\pi_i \circ \pi') \circ \pi = \pi'_i \circ \pi = \pi_i$. That is $\varphi = \pi' \circ \pi$ always satisfies $\pi_i \circ \varphi = \pi_i$ and thereby we conclude $\pi' \circ \pi = \mathbb{1}_P$. In complete analogy we find $\pi'_i \circ (\pi \circ \pi') = (\pi'_i \circ \pi) \circ \pi' = \pi_i \circ \pi' = \pi'_i$ such that $\varphi' = \pi \circ \pi'$ always satisfies $\pi'_i \circ \varphi' = \pi'_i$. Again we get $\pi \circ \pi' = \mathbb{1}_{P'}$ and thereby π and π' are mutually inverse. In particular $\pi : P \xrightarrow{\sim} P'$ is an isomorphism. And by construction $\Phi := \pi$ is the uniquely determined morphism, satisfying $\pi_i = \pi'_i \circ \Phi$ for any $i \in I$.

(ii) The proof follows exactly the same lines, as the proof of (i) above. We present it for completeness purposes, only: Clearly $\varphi = \mathbb{1}_S$ is a morphism $\mathbb{1}_S : S \to S$ satisfying $\varepsilon_i = \varphi \circ \varepsilon_i$. And as (S, ε_i) is a coproduct of the X_i this has to the *only* morphism $\varphi \in \mathcal{C}(S, S)$ that makes all these diagrams commute. Now apply (3) to (S', ε'_i), then we find a morphism $\varepsilon' : S \to S'$ such that $\varepsilon'_i = \varepsilon' \circ \varepsilon_i$.

Likewise (S', ε'_i) is a coproduct of the X_i so by the same reasoning, as above, we see that $\varphi' = \mathbb{1}_{S'} \in \mathcal{C}(S', S')$ is the one and only morphism making all the diagrams $\varepsilon'_i = \varphi' \circ \varepsilon'_i$ commute. And applying (3) to (S, ε_i) we also find a morphism $\varepsilon : S' \to S$ such that $\varepsilon_i = \varepsilon \circ \varepsilon'_i$.

Let us now compose these morphisms ε' and ε: Again we find $(\varepsilon \circ \varepsilon') \circ \varepsilon_i = \varepsilon \circ (\varepsilon' \circ \varepsilon_i) = \varepsilon \circ \varepsilon'_i = \varepsilon_i$. That is $\varphi = \varepsilon \circ \varepsilon'$ always satisfies $\varphi \circ \varepsilon_i = \varepsilon_i$ and thereby we conclude $\varepsilon \circ \varepsilon' = \mathbb{1}_S$. In complete analogy we find $(\varepsilon' \circ \varepsilon) \circ \varepsilon'_i = \varepsilon' \circ (\varepsilon \circ \varepsilon'_i) = \varepsilon' \circ \varepsilon_i = \varepsilon'_i$ such that $\varphi' = \varepsilon' \circ \varepsilon$ always satisfies $\varphi' \circ \varepsilon'_i = \varepsilon'_i$. Again we get $\varepsilon' \circ \varepsilon = \mathbb{1}_{S'}$ and thereby ε and ε' are mutually inverse. In particular $\varepsilon : S \xrightarrow{\sim} S'$ is an isomorphism. And by construction $\Phi := \varepsilon$ is the uniquely determined morphism, satisfying $\varepsilon'_i = \Phi \circ \varepsilon_i$ for any $i \in I$.

(iii) Let us first prove (b) $\Longrightarrow$ (a) for products: To prove that (P, π_i) is a product of the X_i we consider some $U \in \mathrm{obj}(\mathcal{C})$ and some $\varphi_i \in \mathcal{C}(U, X_i)$ and have to find a uniquely determined $\varphi \in \mathcal{C}(U, P)$ such

that $\pi_i \circ \varphi = \varphi_i$ for any $i \in I$. So apply E to this diagram, that is $E(\pi_i) \in \mathcal{D}(E(P), E(X_i))$ and $E(\varphi_i) \in \mathcal{D}(E(U), E(X_i))$. As $(E(P), E(\pi_i))$ is a product of the $E(X_i)$ there is a uniquely determined morphism $\psi \in \mathcal{D}(E(U), E(P))$ such that $E(\pi_i) \circ \psi = E(\varphi_i)$ for any $i \in I$. By (11.31.(ii)) E is full and faithful, that is

$$\mathcal{C}(U,P) \;\longleftrightarrow\; \mathcal{D}\big(E(U),E(P)\big) \;:\; \varphi \mapsto E(\varphi)$$

is bijective. And thereby there is a uniquely determined $\varphi \in \mathcal{C}(U,P)$ such that $E(\varphi) = \psi$. Suppose there was another $\varphi' \in \mathcal{C}(U,P)$ such that $\pi_i \circ \varphi' = \varphi_i$ for any $i \in I$. Applying E to this diagram we get $E(\pi_i) \circ E(\varphi') = E(\varphi_i)$ and thereby $E(\varphi') = \psi = E(\varphi)$. Thus we find $\varphi' = \varphi$ and thereby we have found a uniquely determined φ, as needed for the product property.

(iii) Conversely, let us prove (a) $\Longrightarrow$ (b) for products: To prove that $(E(P), E(\pi_i))$ is a product of the $E(X_i)$ we consider any $V \in \mathrm{obj}(\mathcal{D})$ and some $\psi_i \in \mathcal{D}(V, E(X_i))$ and have to find a uniquely determined $\psi \in \mathcal{D}(V, E(P))$ such that $E(\pi_i) \circ \psi = \psi_i$ for any $i \in I$. By (11.31.(ii)) E not only is full and faithful, but also essentially surjective. That is, there is some $U \in \mathrm{obj}(\mathcal{C})$ such that $\Phi : E(U) \xrightarrow{\sim} V$ are isomorphic. Then $\psi_i \circ \Phi : E(U) \to E(X_i)$ is a morphism, such that by assumption (a) there is a uniquely determined morphism $\varphi_i : U \to X_i$ such that $E(\varphi_i) = \psi_i \circ \Phi$. As P is a product of the X_i there is a uniquely determined $\varphi : U \to P$ such that $\pi_i \circ \varphi = \varphi_i$ for any $i \in I$. Applying E to these diagrams, we get

$$E(\pi_i) \circ E(\varphi) \;=\; E\big(\pi_i \circ \varphi\big) \;=\; E(\varphi_i) \;=\; \psi_i \circ \Phi$$

Now define $\psi := E(\varphi) \circ \Phi^{-1}$ then by the equation above we have $E(\pi_i) \circ \psi = \psi_i$ for any $i \in I$. Thus the existence of ψ is established. Suppose there was another $\psi' \in \mathcal{D}(V, E(P))$ such that $E(\pi_i) \circ \psi' = \psi_i$ for any $i \in I$. Then $\psi' \circ \Phi \in \mathcal{D}(E(U), E(P))$ which corresponds to $\mathcal{C}(U,P)$. That is there is some $\varphi' \in \mathcal{C}(U,P)$ such that $E(\varphi') = \psi' \circ \Phi$. Then we get

$$E(\varphi_i) \;=\; \psi_i \circ \Phi \;=\; \big(E(\pi_i) \circ \psi'\big) \circ \Phi \;=\; E(\pi_i) \circ \big(\psi' \circ \Phi\big) \;=\; E(\pi_i) \circ E(\varphi') \;=\; E\big(\pi_i \circ \varphi'\big)$$

From this we find $\varphi_i = \pi_i \circ \varphi'$ and as this is true for any $i \in I$ and φ is unique with this property, we see $\varphi' = \varphi$. Therefore $\psi' \circ \Phi = E(\varphi') = E(\varphi) = \psi \circ \Phi$ and as Φ is an isomorphism, we conclude $\psi' = \psi$. That is ψ also is uniquely determined.

(iii) It remains to proof the equivalence for coproducts: But it is obvious, that (P, π_i) being a coproduct of the X_i in $\mathcal{C}$ is just the same, as (P, π_i) being a product of the X_i in $\mathcal{C}^{\mathrm{op}}$. And by the above, this is equivalent to $(E(P), E(\pi_i))$ being a product of the $E(X_i)$ in $\mathcal{D}^{\mathrm{op}}$. And this is just $(E(P), E(\pi_i))$ being a coproduct of the $E(X_i)$ in $\mathcal{D}$, again.

□

Proof of (11.38):

(i) Proving the uniqueness (up to isomorphy) of an object satisfying a universal property always follows the same ideas: Let us take (L, λ_i) as a direct target of the direct limit (L, λ_i). That is there is a uniquely determined morphism $\tau : L \to L$ such that $\lambda_i = \tau \circ \lambda_i$ for any $i \in I$. And clearly $\tau = \mathbb{1}_L$ does the trick. Now take (L', λ'_i) as a direct target of the direct limit (L, λ_i). Then we find a uniquely determined morphism $\lambda' : L \to L'$ such that $\lambda'_i = \lambda' \circ \lambda_i$ for any $i \in I$. Likewise let

us interchange the roles of (L,λ_i) and (L',λ'_i). That is we find a uniquely determined morphism $\lambda : L' \to L$ such that $\lambda_i = \lambda \circ \lambda'_i$ for any $i \in I$.

Let us now compose these morphisms λ' and λ: We find $(\lambda \circ \lambda') \circ \lambda_i = \lambda \circ (\lambda' \circ \lambda_i) = \lambda \circ \lambda'_i = \lambda_i$. That is $\tau = \lambda \circ \lambda'$ always satisfies $\tau \circ \lambda_i = \lambda_i$ and thereby we conclude $\lambda \circ \lambda' = \mathbb{1}_L$ as this is the only morphism, that can do the trick. In complete analogy we find $(\lambda' \circ \lambda) \circ \lambda'_i = \lambda' \circ (\lambda \circ \lambda'_i) = \lambda' \circ \lambda_i = \lambda'_i$ such that $\tau' = \lambda' \circ \lambda$ always satisfies $\tau' \circ \lambda'_i = \lambda'_i$. By the same reasoning we conclude $\lambda' \circ \lambda = \mathbb{1}_{L'}$ and thereby λ and λ' are mutually inverse. In particular $\lambda' : L \xrightarrow{\sim} L'$ is an isomorphism.

(ii) The proof follows exactly the same lines, as the proof of (i) above. We present it for completeness purposes, only: Let us take (L,λ_i) as an inverse target of the inverse limit (L,λ_i). That is there is a uniquely determined morphism $\tau : L \to L$ such that $\lambda_i = \lambda_i \circ \tau$ for any $i \in I$. And clearly $\tau = \mathbb{1}_L$ does the trick. Now take (L',λ'_i) as a direct target of the direct limit (L,λ_i). Then we find a uniquely determined morphism $\lambda' : L' \to L$ such that $\lambda'_i = \lambda_i \circ \lambda'$ for any $i \in I$. Likewise let us interchange the roles of (L,λ_i) and (L',λ'_i). That is we find a uniquely determined morphism $\lambda : L \to L'$ such that $\lambda_i = \lambda'_i \circ \lambda$ for any $i \in I$.

Let us now compose these morphisms λ' and λ: We find $\lambda_i \circ (\lambda' \circ \lambda) = (\lambda_i \circ \lambda') \circ \lambda = \lambda'_i \circ \lambda = \lambda_i$. That is $\tau = \lambda' \circ \lambda$ always satisfies $\lambda_i \circ \tau = \lambda_i$ and thereby we conclude $\lambda' \circ \lambda = \mathbb{1}_L$ as this is the only morphism, that can do the trick. In complete analogy we find $\lambda'_i \circ (\lambda \circ \lambda') = (\lambda'_i \circ \lambda) \circ \lambda' = \lambda_i \circ \lambda' = \lambda'_i$ such that $\tau' = \lambda \circ \lambda'$ always satisfies $\lambda'_i \circ \tau' = \lambda'_i$. By the same reasoning we conclude $\lambda \circ \lambda' = \mathbb{1}_{L'}$ and thereby λ and λ' are mutually inverse. In particular $\lambda : L \xrightarrow{\sim} L'$ is an isomorphism.

(iii) Let us first prove (b) $\Longrightarrow$ (a) for direct limits: That is for any direct target (T,τ_i) we need to find a uniquely determined morphism $\tau : L \to T$ such that $\tau \circ \lambda_i = \tau_i$ for any $i \in I$. Let us shift the whole (left-hand) diagram in (11.37) under E. By assumption (b) there is a uniquely determined morphism $\vartheta : E(L) \to E(T)$ such that $\vartheta \circ E(\lambda_i) = E(\tau_i)$ for any $i \in I$. By (11.31.(ii)) E is full and faithful. Hence there is a uniquely determined morphism $\tau : L \to T$ such that $E(\tau) = \vartheta$ and therefore

$$E\big(\tau \circ \lambda_i\big) \;=\; E(\tau) \circ E(\lambda_i) \;=\; \vartheta \circ E(\lambda_i) \;=\; E(\tau_i)$$

such that $\tau \circ \lambda_i = \tau_i$ by faithfulness. That is τ satisfies the properties required. It remains to veritfy its uniqueness: That is we consider any $\tau' : L \to T$ such that $\tau' \circ \lambda_i = \tau_i$. Then we get

$$E(\tau') \circ E(\lambda_i) \;=\; E\big(\tau' \circ \lambda_i\big) \;=\; E(\tau_i) \;=\; \vartheta \circ E(\lambda_i)$$

As this is true for any $i \in I$ we find $E(\tau') = \vartheta = E(\tau)$, as ϑ is unique with this property, and thereby $\tau' = \tau$ by faithfulness, again. Thus τ also is uniquely determined.

(iii) Conversely for (a) $\Longrightarrow$ (b) for direct limits: We have to prove that $(E(L), E(\lambda_i))$ is a direct limit, that is for any direct target (T,τ_i) we need to find some $\tau : E(L) \to T$ such that for any $i \in I$ we have $\tau \circ E(\lambda_i) = \tau_i$. And this τ has to be uniquely determined, by this property. By (11.31.(ii)) E not only is full and faithful, but also essentially surjective. That is we can choose some $S \in \mathrm{obj}(\mathcal{C})$ such that $\Phi : T \xrightarrow{\sim} E(S)$ admits an isomorphism Φ. Then we have $\Phi \circ \tau_i : E(M_i) \to E(S)$ and hence there is a uniquely determined morphism $\sigma_i : M_i \to S$ such that $E(\sigma_i) = \Phi \circ \tau_i$. By assumption

(T, τ_i) is a direct target of $(E(M_i), E(\mu_i^j))$ and therefore $\tau_i = \tau_j \circ E(\mu_i^j)$ for any $i \leq j \in I$. Apply Φ from the left, then we get

$$E(\sigma_i) \;=\; \Phi \circ \tau_i \;=\; \Phi \circ \tau_j \circ E(\mu_i^j) \;=\; E(\sigma_j) \circ E(\mu_i^j) \;=\; E(\sigma_j \circ \mu_i^j)$$

By faithfulness of E that is $\sigma_i = \sigma_j \circ \mu_i^j$ and this means that (S, σ_i) is a direct target of (M_i, μ_i^j). Therefore, by assumption (a), there is a uniquely determined morphism $\sigma : L \to S$, such that $\sigma \circ \lambda_i = \sigma_i$ for any $i \in I$. Take $\tau := \Phi^{-1} \circ E(\sigma) : E(L) \to T$, then we get

$$\tau \circ E(\lambda_i) \;=\; \Phi^{-1} \circ E(\sigma) \circ E(\lambda_i) \;=\; \Phi^{-1} \circ E(\sigma \circ \lambda_i) \;=\; \Phi^{-1} \circ E(\sigma_i) \;=\; \Phi^{-1} \circ \Phi \circ \tau_i \;=\; \tau_i$$

That is τ satisfies the properties required for a direct limit. It remains to verify the uniqueness: Suppose we had another morphism $\tau' : E(L) \to T$ such that for any $i \in I$ we get $\tau' \circ E(\lambda_i) = \tau_i$. Then $\Phi \circ \tau' : E(L) \to E(S)$ and thereby there is a (uniquely determined) $\sigma' : L \to S$, such that $E(\sigma') = \Phi \circ \tau'$. Then we find

$$E(\sigma' \circ \lambda_i) \;=\; E(\sigma') \circ E(\lambda_i) \;=\; \Phi \circ \tau' \circ E(\lambda_i) \;=\; \Phi \circ \tau_i \;=\; E(\sigma_i)$$

By faithfulness of E this is $\sigma' \circ \lambda_i = \sigma_i$ again, and as this is true for any $i \in I$ and σ is unique with this property, we conclude $\sigma' = \sigma$. In particular $\Phi \circ \tau' = E(\sigma') = E(\sigma) = \Phi \circ \tau$. And as Φ is an isomorphism we may apply Φ^{-1} from the left to find $\tau' = \tau$ which also is the uniqueness of τ.

(iii) It remains to proof the equivalence for inverse limits: But it is obvious, that (L, λ_i) being an inverse limit of (M_i, μ_j^i) in $\mathcal{C}$ is just the same, as (L, λ_i) being a direct limit of (M_i, μ_j^i) in $\mathcal{C}^{\mathrm{op}}$. And by the above, this is equivalent to $(E(L), E(\lambda_i))$ being a direct limit of $(E(M_i), E(\mu_j^i))$ in $\mathcal{D}^{\mathrm{op}}$. And this is just $(E(P), E(\lambda_i))$ being an inverse limit of $(E(M_i), E(\mu_j^i))$ in $\mathcal{D}$, again.

□
